Effects of oral and oropharyngeal cancer on speech intelligibility using acoustic analysis: Systematic review

Mathieu Balaguer MSc1,2 | Timothy Pommée MSc2 | Jérôme Farinas PhD2 | Julien Pinquier PhD2 | Virginie Woisard MD, PhD1,3 | Renée Speyer PhD4

Abstract

Background: The development of automatic tools based on acoustic analysis allows to overcome the limitations of perceptual assessment for patients with head and neck cancer. The aim of this study is to provide a systematic review of literature describing the effects of oral and oropharyngeal cancer on speech intelligibility using acoustic analysis.

Methods: Two databases (PubMed and Embase) were surveyed. The selection process, according to the preferred reporting items for systematic reviews and meta-analyses (PRISMA) statement, led to a final set of 22 articles.

Results: Nasalance is studied mainly in oropharyngeal patients. The vowels are mostly studied using formant analysis and vowel space area, the consonants by means of spectral moments with specific parameters according to their phonetic characteristic. Machine learning methods allow classifying “intelligible” or “unintelligible” speech for T3 or T4 tumors.

Conclusions: The development of comprehensive models combining different acoustic measures would allow a better consideration of the functional impact of the speech disorder.

KEYWORDS

acoustics, head and neck cancer, intelligibility, oncology, speech

1INTRODUCTION

Head and neck cancer (HNC) has major functional repercussions on the upper aerodigestive tract (breathing, swallowing, and phonation/speech). Because of the sensory-motor impairment related to the presence of the tumor in the anatomical regions involved in the articulation of the speech, a functional impairment at the level of communication is likely to appear.1 The speech-related quality of life will also be impacted.2,3

In this oncological context, various factors can affect the quality of speech, including the treatments, the size of the tumor,4-6 or its location.7,8

With the increasing rate of oropharyngeal cancer incidence,9,10 the evaluation of speech and its disorders becomes a major issue in the management of patients with HNC.

This evaluation is mainly based on a perceptual assessment: therapists, mainly speech pathologists, assess the quality of the patient’s speech production. But these methods have two major limitations. First, most of the tools are intended for voice quality assessment in laryngeal cancers,11 whereas speech disorder is the most common symptom in cancers of the oral cavity and the oropharynx.12 Second, these measures are known to show great interjudge and intrajudge variability. Indeed, the reliability of the perceptual estimates is mostly listener-dependent.13 The degree of
familiarity of the listener with the patient or with the task might increase predictability and improve the functional speech scores given by the rater. The rating by an expert in the pathology field or by a rater who is familiar with the patient can be very different of that by a naive listener. Moreover, the reproducibility of the perceptual assessment is also subject to intrajudge variations. The emotional context or the mental alertness of the judge at the time of the assessment may influence the outcome.

Recently, the technology development allows investigating new tools for speech evaluation, based on objective data. For this purpose, acoustic speech analysis is currently a growing field of research.

1.1 | Review question

The aim of this article is to provide a systematic review of literature describing the effects of HNC on speech intelligibility using acoustic analysis. This review will focus on speech intelligibility in adults with oral or oropharyngeal cancer assessed by acoustic measures.

2 | MATERIALS AND METHODS

2.1 | Ethical approval

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

2.2 | Protocol and registration

The methodology and reporting on this systematic review were guided by the preferred reporting items for systematic reviews and meta-analyses (PRISMA) statement and checklist. The PRISMA statement and checklist are designed to guide researchers in the essential and transparent reporting of systematic reviews.

2.3 | Eligibility criteria

To be eligible for inclusion in this systematic review, articles were required to describe the effects of oral and oropharyngeal cancer on speech intelligibility using acoustic analysis. Only articles with the following criteria were included:

- Assessment of speech intelligibility,
- Use of acoustics and related terms (such as acoustic analysis, phonetics, signal processing, sound spectrography, etc),
- Patients with oral or oropharyngeal cancer.

In this study, speech intelligibility is defined as the level which a message can be understood by a listener, the proportion of understood speech, or the correctly transcribed word rate. Speech intelligibility impairment is described as the functional speech deficit decreasing the ability to interact with someone else.

Exclusion criteria were:

- The absence of the original larynx (exclusion of total or partial laryngectomies, larynx prostheses, etc),
- Studies addressing children populations,
- Papers that were not original articles, such as abstracts, conference proceedings, and reviews,
- Case studies,
- Articles not published in English.

2.4 | Data sources and search strategies

A literature search was performed in two different electronic databases, to gather relevant literature: PubMed and Embase. These two databases were selected based on the subject of this research. Note that a third database, Web of Science (WoS), did not retrieve any new reference.

All publications dated up to December 4, 2018 were included, with no limitations regarding the publication dates. The search terms are listed in Table 1.

All abstracts were reviewed by two independent raters. Differences of opinion about the eligibility of articles were settled by consensus. A flowchart of the selection process according to PRISMA is shown in Figure 1.

2.5 | Methodological quality and level of evidence

The National Health and Medical Research Council (NHMRC) Evidence Hierarchy was used to assess the level of evidence, from I (Systematic reviews) to IV (Case series).

The QualSyst critical appraisal tool by Kmet et al provides systematic, reproducible, and quantitative means of assessing the methodological quality of research over a broad range of study designs. A QualSyst score higher than 80% was interpreted as strong quality, 60% to 79% as good quality, 50% to 59% as adequate quality, and lower than 50% as poor methodological quality. Studies with poor methodological quality were excluded from further analysis.

2.6 | Data extraction

After assessment of methodological quality, data from all remaining articles were extracted for the following categories: number of participants in the study and their characteristics (age, diagnosis, and language spoken), acoustic parameters.

(and their definitions), comparison criterion/a, speech sample, and authors’ main conclusions.

Additionally, geographic bibliometric data were extracted using the Netscity tool\(^1\) (by the Netscience project of the Labex SMS, Toulouse, France).

### 3 | RESULTS

#### 3.1 | Study selection

A total of 488 records were retrieved from the two electronic databases. Two independent reviewers screened all records and assessed 196 full-text articles for eligibility. A final total of 22 articles met the inclusion criteria and were included in this review (see Figure 1).

#### 3.2 | Quality assessment

The overall quality of the studies, as assessed by the QualSyst tool, ranged from “good” to “strong,” with four studies ranked as “good” and 18 as “strong.”

\(^1\)https://www.geotests.net/netscitypg/index.php.

Based on the NHMRC evidence hierarchy,\(^2\) 20 studies were classified as level III evidence (14 as III-3; “Comparative studies with two or more single-arm studies”; six as III-2; “Comparative studies with concurrent controls and allocation not randomized [cohort studies], or case control studies”), and two as level IV evidence (Case series). No article of a low level of evidence had to be excluded. The ratings of all 22 included articles are listed in Table 2.

The full outcome table on the 22 retained articles can be found in Appendix A.

### 3.3 | Bibliometric data

The field of acoustic parameters in speech analysis in patients treated for HNC mainly concerns teams located in three geographical areas: Western Europe (mainly the Netherlands), North America, and the Far East (Japan and South Korea). Some collaborations between teams are noted: between Finland and Canada, and between South Korea and the United States (see Figure 2).

This will have an influence on the languages of the study speech samples.
Most of the studies selected in this review have been published since 2010 (13/22, 59%). The use of cepstral coefficients and of machine learning tools in speech assessment in an oncological context started around 2010 (see Figure 3). The field of speech acoustic analysis is therefore growing, due to the recent use of new acoustic measures.

### 3.4 | Participants

Among the 22 studies, 10 include more than 20 patients,25,29,32-34,40,43 and also 10 include between 2 and 18 subjects.24,31,35,37-39,41,42,44,45 Two articles do not report the number of subjects involved in the acoustic analysis.30,36 Details are given in Table 3. Note that with the exception of two studies,24,45 the subjects included are mostly men.

Two studies30,34 use patient data from retrospective corpora.

All participants in the 22 studies had cancers of the oral cavity or of the oropharynx at the time of the study.

In total, 11 studies (50%) address patients treated for cancer of the oral cavity only. The anatomical sites mainly (9/11) involve the tongue (treated by total28,35,38,39,43,44 or partial glossectomy.24,31,33). The remaining two studies investigate maxillary tumors.37,45

Six studies (27%) include both patients treated for cancer of the oral cavity and patients treated for oropharynx cancer.26,27,29,30,34,40

Only five (23%) include only patients with an oropharyngeal tumor location. Two addressed patients with a tumor extension to the soft palate.41,42 The other three relate to the tonsil, alone25 or in comparison to the area of the base of the tongue.32,36

The distribution of the tumor locations is illustrated in Figure 4.

Regarding the size of the tumor, 12 studies (54%) include smaller tumors (T1 + T2) than large ones.25-27,29,31,33,37-40,43,44 Three studies (14%) focus on larger tumors (T3 + T4).30,34,42 One study (5%) includes as many subjects with small T1 + T2 tumors than with larger T3 + T4 tumors (T3 + T4).41

Last, six studies (27%) do not report the size of the tumor of participants.24,28,33,36,37,45

Figure 5 shows the detailed proportion of the tumor sizes across the studies that reported these sizes.

Of the 22 included studies, 20 (91%) address surgically treated patients. Among them, surgery was carried out exclusively (with no reported information about complementary treatment) in 14 studies, including seven surgical reconstructions.25-29,31,33,37-40,43-45 Surgery was combined with other treatment methods such as radiotherapy or
chemotherapy in six studies. Finally, a radio-
chemotherapy without surgical treatment was performed for
the participants of two studies (9%).

The main languages spoken by the subjects and thus
constituting the speech sample are English (including
American English and Canadian English) and Dutch in four
studies, respectively. The remaining studies are all
carried out in different languages: French, Portuguese,
German, Finnish, Hindi, Japanese, and Korean. Seven studies do not report the language.

3.5 Comparison outcomes

The different comparison outcomes used in the studies are
shown in Table 4.

Six studies (27%) compare acoustic measures with a per-
ceptual outcome. The latter is an intelligibility score assigned
by judges using a Likert-type ordinal scale, either globally or
on specific parameters such as articulation, nasality, or

weakness.

One study uses the percentage of correct
identified consonants.

Five studies (23%) investigate the performance of acous-
tic scores either by analyzing differences between the invest-
gigated parameters or by comparing the results with existing
data: comparison of formants, comparison of the perfor-
mance of two spectral parameters, and comparison with
the same parameters from other software or with existing
norms.

Three studies (14%) compare acoustic parameters before
and after treatment. Eventually, eight studies (36%)
compare the same parameters between a subject and a con-
trol group.

3.6 Speech samples

Fourteen studies measure acoustic parameters in isolated
phonemes. Specifically, eight analyze sustained vowels,
three analyze phonemes extracted

| Takatsu et al              | 19/20 (95%)        | Strong              | III-3                   |
| Wakumo et al               | 18/20 (90%)        | Strong              | III-3                   |
| Yoshida et al              | 19/20 (95%)        | Strong              | III-3                   |

Methodological quality: strong (>80%); good (60%-79%); adequate (50%-59%); and poor (<50%).

NHMRC hierarchy: Level 1, systematic reviews; level II, randomized control trials; level III-1, pseudo-randomized control trials; level III-2, comparative studies with concurrent controls and allocation not randomized (cohort studies), case control studies, or interrupted time series with a control group; level III-3, comparative studies with historical control, two or more single-arm studies, or interrupted time series without a control group; level IV, case series.
from a read text,26,27,38 and two from isolated words.31,39 One study analyzes both sustained vowels and words (formants and their transitions43).

One study carries out analyses at the sentence-level,40 and four use a more global analysis on a read text.25,30,34,41 One study does not report the composition of its speech sample.32

These results are shown in Table 5.

FIGURE 2 World location of authors' affiliations, and collaborations between research teams [Color figure can be viewed at wileyonlinelibrary.com]

FIGURE 3 Number of articles selected per year (the numbers inside the bar charts are the reference of the article)
3.7 | Acoustic measures

The acoustic parameters analyzed in the included studies, reported below, are shown in Appendix B. Figure 6 represents the distribution of the units of analysis in the articles.

3.7.1 | Nasalance (seven articles)

Seven articles focus on the analysis of nasality. Three studies carried out the nasalance analysis on vowels,³²,³⁶,³⁷ one on sentences,⁴⁰ and two on a read text.²⁵,⁴¹ One study does not report the speech unit used.⁴²

Most of the studies compute a nasality score by using dedicated software (Praat,³⁶ Dr. Speech³⁷) or nasometers.⁴⁰-⁴² The ratio of the acoustic energy emerging from the nasal and from the oral cavity is calculated in two studies.²⁵,³²

Nasalance score presents a significant association with perceptual assessment, in extended resection or reconstruction of the soft palate.²⁵ Four other studies show an increased nasalance after treatment.³²,³⁶,³⁷,⁴² One study shows that oral cavity tumors do not have a significant impact on the nasality in contrast to oropharyngeal tumors.⁴⁰

| Comparison outcome | Number of studies (%) |
|--------------------|-----------------------|
| Perceptual assessment | 6 (27%) |
| Global intelligibility | 1 |
| Specific parameters: articulation, nasality, “weakness” | 4 |
| Percent correct identification of consonants | 1 |
| Difference analysis | 5 (23%) |
| Formants | 1 |
| Spectral parameters | 2 |
| Parameters or existing norms from software | 2 |
| Same parameters before/after treatment | 3 (14%) |
| Same parameters in subjects and controls | 8 (36%) |

---

**FIGURE 4** Tumor locations

**FIGURE 5** Detailed proportion of the tumor size (T classification) in the retained articles (note that articles 26 and 27 do not differentiate T3 and T4 sizes in the 25 participants)
3.7.2 | Vowels (nine articles)

Nine articles study the first and second formants (F1 and F2) of vowels.26,28,29,31,33,35,39,43,45 Of these, three also study F328,31,33 and one analyzes formants up to F12.45 The vowel space area (VSA) is used in two studies26,43 and the transition slope is only found in one.43

Four studies investigate acoustic differences before and after treatment. After tongue surgery, significant differences are found in F1 and F2,35,39 with F1 generally being increased and F2 being lowered. The acoustic measures are impacted by local reconstruction,43 as well as by a well-adapted palate-lowering prosthesis, which is shown to modify F1, F2, and F3 in patients treated for a subtotal glossectomy.28 Two studies show a correlation between acoustic measures and perceived intelligibility: F2 of /i/ ($r = 0.35$) and the size of the VSA are linked with intelligibility ($r = 0.39, P < .05$) and articulation ($r = 0.42, P < .05$) ratings.26 and F7 and F12 of /i/ are also highly correlated with perceptual ratings ($r = 0.84$).45 A single study does not find any significant correlation between acoustic and perceptual assessment on F0, F1, and F2.29

The studies comparing subjects and healthy controls find that F2 and F3 are lower in the patient group.31 For women, significant correlations are found between subjects and controls for F2 and F3, but only for F1 for men.33

3.7.3 | Consonants (five articles)

Three studies analyze spectral moments on plosives and fricatives: the center of gravity/spectral mean24,32,38 and the spectral skewness.24,26,38 The Klatt Voice Onset Time (VOT) is also analyzed on both consonant groups in one study.24

On plosive consonants, the duration of air pressure release is measured twice.26,32 The /t/ consonant peak energy frequency and the formant transition in the syllable /ta/ are analyzed in Reference 44.

On fricatives, the friction duration and the band energy are calculated in two studies.32,38 In Reference 32, F1, F2, and F3 are measured on liquids /l/ and /r/.

The results show that the duration of the air pressure release in /k/ is linked with intelligibility and articulation estimates.26 In addition, the center of gravity and the skewness correlate with the perceptual evaluation in specific contexts (iCi and αCα context).24 The comparison pretreatment vs post-treatment allows considering the spectral mean and

**TABLE 5** Constitution of the speech samples

| Speech sample                       | Number of studies (%) |
|-------------------------------------|-----------------------|
| Isolated phonemes                   | 14 (64%)              |
| Sustained vowels                    | 8                     |
| Extracted from a read text          | 3                     |
| Extracted from isolated words       | 2                     |
| Combination of sustained vowels and phonemes in words | 1 |
| Syllables and diadochokinesis       | 2 (9%)                |
| Sentences                           | 1 (5%)                |
| Read text                           | 4 (17%)               |
| Not reported                         | 1 (5%)                |

**FIGURE 6** Number of studies analyzing the categories of acoustic parameters
the skewness as good measures for short-term effects, and friction duration on /s, z/ does not seem to be relevant for long-time effects. One year after chemoradiotherapy, the spectral burst peak frequency of /k/ is weakened, a significantly higher F3 with lower intensity is found on /l/, and a significant higher spectral burst frequency on /t/ (higher spectral burst frequency) is noted. Across different contexts, the Klatt VOT seems congruent with the perceptual assessment. Last, the formant variance F2-F3 at the transition between plosive and vowel returns to normal after surgery, and the consonant peak energy frequency is lower presurgery for some subjects.

3.7.4 | Global speech (three articles)

Two articles study the performance of different acoustic features, computed from existing corpora, in order to classify speech into two categories (intelligible/unintelligible). The investigated features are: Mel-frequency cepstral coefficients (MFCC) and Mel S-transform cepstrum coefficients (MSCC) in Reference 30 and multiresolution sinusoidal transform coding (MRSTC) in Reference 34. These features are fed to different classifying algorithms that output a binary decision on the intelligibility: article 34 uses a regression-based classifier, article 30 a support vector machine (SVM). A third article uses an artificial neural network (ANN) to predict articulation quality and nasalance.

MSCC yield better results than MFCC in classifying intelligible and unintelligible speech on retrospective corpora, and MRSTC show a better classification when they are fed to an SVM. ANNs significantly predict perceived articulation quality on /i/ and /u/, as well as perceptual hypernasality on /i/ and /u/.

4 | DISCUSSION

The main goal of this study was to review the scientific literature studying the effects on speech intelligibility of oral or oropharyngeal cancer, using acoustic parameters.

Two main lines of thought emerge from the analysis of the 22 selected articles, regarding the choice of the acoustic parameters, and the unit of analysis chosen to assess intelligibility.

4.1 | Acoustic parameters according to participants' characteristics

If we look at the most investigated acoustic analyses used in the studies retained for this review, two main fields can be determined: the nasality measures and the vowel acoustics.

The location of the tumor plays a role in the choice of the acoustic parameter. Most of the studies, including patients with oropharyngeal cancer, use nasalance measures as one of the criteria impacting intelligibility. Among these studies, five include only oropharyngeal cancer and two include patients undergoing surgery for the oropharynx or the cavity oral. The oropharyngeal pathology, because of its location, has an impact on the dynamics of the anatomical structures that account for speech nasality, particularly by its effect on the soft palate or the tonsil.

The majority of the studies, including patients with oral cavity cancer, analyze acoustics on vowels and consonants. If nasalance is mainly assessed at a sentence or text level, most of the other analyses, however, focus on the acoustic characteristics of isolated vowels, produced singly or more rarely extracted from syllables or continuous speech. The analyses are mainly carried out on the first formants, which are known to be directly impacted by the oral pathology: the opening of the jaw modifies F1 and the position of the tongue modifies F2. The studies making the link between these formant measures and perceived intelligibility (perceptual comparison criteria are used in three articles out of nine addressing formant measures) put forward the interest of three main parameters: the size of the VSA, F2 in the vowel /i/, and ANN-based nasalance scores on /i/.

Regarding the analyses on consonants, their type induces the use of different acoustic parameters. On the plosives [p t k], the spectral analysis of the burst and the air pressure release seem relevant. The center of gravity, spectral slope, and band energy are more commonly used for fricatives.

Thereby, the acoustic parameters analyzed depend on the location of the tumor: the analyses on vowels and consonants relate mainly to oral cavity patients, whereas nasalance concerns mainly patients treated for oropharynx cancer. This is congruent with the expected functional impact of the morphological and dynamic changes consecutive to the treatment. It therefore seems appropriate to adapt the choice of acoustic parameters to the pathology presented by the patient in the clinical assessment.

Regarding the size of the tumor, the intelligibility in the context of small tumors is mainly analyzed on vowels (mostly formant analysis), and on consonants (spectral moments). Nasality is only investigated in one study, using an ANN on vowels.

The three studies including larger tumors mainly use cepstral coefficients (MFCC, MSCC, MRSTC). The use of feature extraction and of neural networks is fairly recent in the field of intelligibility assessment and shows promising performances in terms of intelligible/unintelligible binary classification, with the perceptual judgment as the external validation criterion.

The size of the tumor, in accordance with the impact on the anatomical structures involved in speech production,
seems to determine the acoustic criteria. Phoneme-specific acoustic parameters are thus mainly used in tumors of small volumes, having a lesser impact on speech dynamics. Regarding tumors of larger volumes, studies look for more general speech-quality parameters to categorize speech as intelligible or unintelligible.

Subcategory analyses by treatment and by language did not reveal any trend, particularly because of the small numbers of studies and patients in each category. Only two languages are found in more than one article: English and Dutch in four studies. Among them, two analyzes the same cardinal vowels and the first two formants: they show different results regarding the correlation between these scores and the perceptive assessment of intelligibility. More studies are thus required to specifically study the effect of the phonemic constitution of a language on patients' intelligibility after treatment.

To summarize, a tight link seems to exist between the acoustic parameters and the tumor location, as well as between these parameters and the tumor size. Moreover, there is a great variability in acoustic parameters used in the different studies, mainly at the segmental level. The use of cepstral parameters and machine learning tools allows continuous speech analysis, but these techniques are still very recent and research needs to be developed. Currently, acoustic parameters seem to be relevant to complete the perceptual assessment of speech, carried out in current practice. It would therefore seem appropriate to investigate more comprehensive analysis models that not only classify patients' speech according to their functional intelligibility performance, but also study the fine acoustic impact of a tumor to enable targeted management of analytic deficits.

### 4.2 Speech samples

The analysis of the speech samples on which the acoustic parameters are measured shows a predominance of the study of isolated phonemes (vowels or consonants). Sentences or texts are rather used for the measurement of cepstral coefficients (such as MFCC or MSCC) or nasalance.

However, in a functional point of view, the analysis of semi-spontaneous or spontaneous speech would be the closest way to predict the intelligibility in the patient's daily life. From our review, we notice that there are no studies on such tasks, such as an image description or spontaneous speech analysis.

### 4.3 Study limitations

This systematic review surveyed two databases (PubMed and Embase). The WoS was also surveyed, but no entry was found that was not also present in the first two databases (ie, all articles found in the WoS were duplicates of the PubMed and Embase entries). However, it is not excluded that other studies exist outside the scope of this search.

In the 22 articles that were selected, two studies were carried out on identical or very similar corpora: References 26 and 27 and References 38 and 39. However, both were retained because the main objectives were different and complementary: Reference 26 focused on formant analysis while Reference 27 used ANN; Reference 38 investigated the analysis of the spectral moments on consonants, while Reference 39 studied formants in vowels.

The great variability of the included studies underlines the need for the development of standarized tools of acoustic evaluations in patients treated for HNC. Standardization can enable to carry out more precise and reliable assessments in the diagnosis of speech disorder and its severity, but also in intraindividual comparisons in patient follow-up.

### 4.4 Future directions for research

Numerous acoustic parameters allow differentiating subjects suffering from cancer of the oral cavity or of the oropharynx, from healthy controls. This is the case for formant analysis mainly in cancers of the oral cavity, but also for nasality scores in two studies. The clinical validity of these measures has thereby been underlined. Other parameters allow the measurement of a change before/after treatment, such as spectral burst frequencies on /t/ and /k/ or nasalance scores for patients with oropharyngeal cancer, and F1 and F2 for patients with oral cavity cancer. These parameters therefore show a good responsiveness.

However, one important question still needs to be addressed: Which golden standard can be used to evaluate the criterion validity of these different parameters? Six studies choose the perceptual evaluation as a golden standard, which is currently the standard in clinical practice. The discussion on the choice of this golden standard remains open.

When conducting our initial database search, the inclusion term “intelligibility” has led to many articles not addressing speech per se, but the quality of voice. It seems that no consensus is reached in the literature regarding the definition of intelligibility.

Moreover, most of the studies focused on the quality of acoustic-phonetic decoding on phonemes (vowels and consonants), to account for the speech intelligibility. However, there are several additional factors that can affect the quality of speech. The inclusion of other elements of the speech signal in addition to the acoustico-phonetic decoding—such as nasality, speech rate, and other temporal and/or prosodic parameters related to perceived impairment—defines the more complex notion of speech disorder severity.
The differentiation between the notions of intelligibility and severity of a speech disorder can also be applied to the question of the impact of these disorder levels at a functional (ie, communication) and at a psychosocial level.

The automatic speech analysis is mainly performed at the segmental level, which is a context allowing a better control of the speech production of the patient. Speech assessment on a read text, which is a semi-spontaneous speech, allows controlling the context of speech production. Although the majority of the speech units from the selected studies are isolated phonemes, and more rarely sentences or texts, none investigated semi-spontaneous or spontaneous speech. True spontaneous speech is based on nonconstrained productions, such as conversational speech. But the automatic analysis of this spontaneous speech is more complex to perform because it does not allow any reference to which comparing the performance of the patient, and that it includes many associated linguistic dimensions (phonemic, lexical, syntactic, prosodic). However, the functional impact of the speech disorder lies in the decrease of the patient’s ability to transmit a message. Despite these challenges, acoustic measurements on spontaneous speech need to be developed. This context of production is the closest to communication situations experienced by patients on a daily basis, in communication with peers. Thus, the development of automatic tools objectively measuring speech on picture-description task or spontaneous speech (such as talking about the last holidays), using specific parameters (eg, acoustics on phonemes, coarticulation, prosody, speech rate, etc) seems to be an interesting lead for future research, facilitated by the recent evolution of technology.48 Within a perspective of speech evaluation closely reflecting the patient's daily production, the functional impact of the speech disorder must be taken into consideration.

Thus, an overall assessment of speech seems relevant. It would include an objective assessment using specific acoustic measures—specifically according to tumor location—a perceptual evaluation (which is more global because it involves the complexity of speech disorder perception), and new tools for measuring the functional speech impairment (such as self-questionnaires). On the one hand, this would allow a more reliable and accurate assessment of deficits caused by the tumor or its treatment. Relevant linguistic units are to be searched and studied in speech signal to improve the intelligibility measurement of speech production disorders. On the other hand, this overall assessment could better take into account the functional consequences on daily life communication, by the assessment of associated deficits or communication needs. Indeed, the correlation between severity of speech impairment perceptively assessed and quality of life is only moderate.4 A multidimensional assessment of speech disorders will allow customizing the therapeutic protocols in rehabilitation by capturing new information in speech signal and targeting more objectively deficits and, but also anticipating the functional and psychosocial impact by adapting therapeutic strategies. Moreover, the automatic acoustic analysis tools, in addition to categorizing speech into intelligible/unintelligible, could also be used to determine finer cutoff points for speech disorder severity levels, depending on the functional impact.

5 | CONCLUSION

Speech assessment in patients with cancer of the oral cavity or of the oropharynx by objective acoustic measures is in development. While many studies focus on the acoustic analysis of isolated phonetic features, the link with functional consequences and psychosocial repercussions must be studied.

More studies are needed to develop new automatic tools and to study which information they allow eliciting about the self-perceived impairment and the speech-related quality of life.

ACKNOWLEDGMENTS

This research was funded by the Hospitals of Toulouse (France), and Grant ANR-18-CE45-0008 from The French National Research Agency in 2018 RUGBI project “Improving the measurement of intelligibility of pathological production disorders impaired speech” led by Jérôme Farinas at IRIT. We thank Dr. Guillaume Cabanac from the Information Retrieval and Information Synthesis team (IRIT, Toulouse) for his help with the online tool Netscity, allowing us to gather the bibliometric data of the retained articles.

## APPENDIX A  EFFECTS OF ORAL AND OROPHARYNGEAL CANCER ON SPEECH INTELLIGIBILITY USING ACOUSTIC ANALYSIS

| Reference | Design (according to NHMRC) | QualSys by Kmet et al | Participants, diagnosis, language | Patients’ age | Acoustic parameters (definitions) | Comparison criteria | Speech sample | Author(s) main conclusion(s) |
|-----------|-----------------------------|-----------------------|-------------------------------|--------------|----------------------------------|---------------------|--------------|-----------------------------|
| Adher et al<sup>24</sup> | IV                           |                       | Participants: 2 patients (1 M, 1 F) with hemi-glossectomy and bilateral neck dissection, chemoradiotherapy | Patient 1: M, 28 y, Patient 2: F, 62 y | “Spectral moments” (energy in frequency domain): COG (first moment): average of frequency distribution of spectral energy. Kurtosis: not seem to be an efficient parameter in this context. | Measure: 5-point scale on intelligibility (1-5: normal to unintelligible) | 24 CVCCV: The median consonant is analyzed when it is surrounded by a symmetrical vowel context (i-i, u-u, o-o). | COG and skewness: changes correspond with the perceptual evaluation of a large majority of the analyzed consonants in the /i/-i/ and /a/-a/ context. Kurtosis: not seem to be an efficient parameter in this context. Klatt VOT: congruent with the perceptual evaluation when the latter could not be explained by spectral parameters. |
| Chung et al<sup>25</sup> | III-3                        |                       | Participants: 53 patients (48 M, 5 F) surgically treated for tonsil cancer (squamous cell carcinoma) | 56.7 y, range 39-80 y | Nasalance: calculation of the ratio of acoustic energy output of nasal sounds from the nasal and OC | Measure: percentage of correct identification of consonants | Reading a no nasal passage, and a high nasal passage | Demurred reconstruction technique (P<.001), extent of soft palate resection (P = .001), and T-stage (P<.001) were significantly associated with the nasalance score assessed objectively and perceptively (Demurred reconstruction: P = .001, extent of soft palate resection: P<.001, T-stage: P = .01) |
| de Buin et al<sup>26</sup> | III-2                        |                       | Participants: 51 patients (28 M, 23 F) treated surgically (with reconstruction) for advanced oral or OP squamous cell carcinoma (21 OC, 30 oropharynx). Included 6 mo after treatment | 53.8 y, SD 8.7, Range: 25-73 y | Vowel formants (i/i, /i/, /a/): F1: first formant frequency associated with ‘height’ (degree of opening of the vocal tract). F2: second formant frequency associated with the anterior-posterior tongue position. Size of vowel space area (area of the vowel triangle) amount of reduction in the vowel systems measured in Hz. Analysis of the velar consonants: /k/: duration of air pressure release (short silent period of pressure building + the pressure release). /K/: spectral slope. | Measure: correlation coefficients between objective parameters and subjective blinded assessment of articulation and nasal resonance (using a 4-point scale) | On vowels: F1/i:/ r = 0.42 with nasal resonance. F2/i:/ r = 0.35 with intelligibility and articulation. Comparison between subjective assessment and size of vowel area: r = 0.39 (P < .05) with intelligibility, r = 0.42 (P < .05) with articulation. On velar consonants: /k/: r > 0.40 (significantly different) for with intelligibility and articulation. Parameters involved in prediction of intelligibility: duration of air pressure release on /k/, size of vowel space and F1/V (P < .05). |

|-----------|-----------------------------|-------------------------|---------------------|---------------|----------------------------------|----------|---------------------|---------------|-----------------------------|
| de Bruij et al\(^{27}\) | IB-2 | 20/22 91% (strong) | Participants: 51 patients (28 M, 23 F) treated for advanced oral or OP squamous cell carcinoma (21 OC, 30 oropharynx) | 53.8 y, SD 8.7 Range: 23-73 y | ANNs: feature representation of an input speech signal, contain a number of model parameters (weights of the connections between network nodes) that determine the relation between input (in this article, input context of seven input MFCC) and output (specifically nasalance in this study): ANN-nasalance | ANN-nasalance (ANN-nasalance): multivariate linear (for intelligibility) or logistic (for articulation quality and hypernasality) regression to obtain insight into the role of objective parameters in subjective speech evaluation (blind assessment of articulation and nasal resonance using a 4-point scale) | Two realizations of cardinal vowels in Dutch (/i/, /u/, /a/) in different phonological contexts (stop consonants, liquid consonants, and nasal consonants) | Predictions by the amount on nasalance (ANN-nasalance): Intelligibility ($R^2 = 21.3\%$); second realizations of /a/ ($P = .01$) and /i/ ($P = .02$) | Articulation quality ($R^2 = 48.7\%$); second realization of /i/ ($P = .05$) | Hypernasality ($R^2 = 24.9\%$): first realizations of /i/ ($P = .05$) and /u/ ($P = .01$) | Analyses on /i/ and /u/ predict articulation quality, on /i/ and /u/ predict hypernasality assessed perceptually |
| de Carvalho-Teles et al\(^{28}\) | IB-3 | 18/22 82% (strong) | Participants: 36 patients (33 M, 3 F) with total or subtotal glossectomy or hemiglossectomy and using a stable and well-adapted palate-lowering prosthesis for at least 3 mo. | Range 30-80 y | Spectrographic assessment of the formants (mean values of F1, F2, and F3 extracted from the most stable part of each vowel held 5 s approximately) of the seven vowels of Brazilian Portuguese, with and without the prosthesis | Measure: | Repetition of 18 syllables with and without prosthesis | With and without the prosthesis: F1: statistically significant differences for /i/, /ê/, /a/ ($P < .005$), and statistical trend for difference for /ó/ ($P = .09$). F2: significant difference for /i/, /ê/, /ó/ ($P < .001$) and statistical trend for /i/, /ô/, /ó/ ($P = .06$ and $P = .08$, respectively). F3: significant difference for /i/, /ê/, /ó/ ($P < .001$) (analysis of variance, $P < .001$). |
| Dwivedi et al\(^{29}\) | IB-2 | 24/24 100% (strong) | Participants: 62 patients (41 M, 21 F) with OC (13 tongue, 9 floor of mouth) and OP cancer (41:13 base of tongue, 26 tonsil, 2 soft palate), surgically treated | Mean: 58.9 y | F0, F1, and F2 analyzed on the mid-stable portion of the sustained vowel /i/ (containing the maximum possible periods—not fewer than 200 ms for F0). LPC technique to evaluate the F1 and F2 formant frequencies | Measure: | Sustained vowel /i/ at a comfortable pitch and loudness (at least 5 s) | Lack of correlation between F1 and F2 on /i/ and perceptual speech parameters (overall, intelligibility and articulation grade) ($P > .15$) | In patients: F1: affected by the elevation of the tongue, mouth closure, and pharyngeal constriction. F2: increased with elevation of the anterior tongue or depression of the posterior region of the OC. F0: rise in male patients with OC cancer (especially oral tongue). |
| Fang et al\(^{30}\) | IB-2 | 14/20 70% (good) | Corpus 1 NKI-CCRT (Clapham, 2012): 55 patients (45 M, 10 F) with head and neck cancer surgery and chemotherapy | Not reported (but reference to Clapham, 2012: mean 58 y, range 32-79) | MFCC MSCE: S-transform is a time-frequency analysis method which combines the advantage of wavelet transform with short-time Fourier transform (better antinoise, time resolution) | Measure: Sensitivity (Se), specificity (Sp), AU, and Accuracy calculated on MFCC and MSCC in two groups | Corpus 1: reading German neutral text Corpus 2: recordings of vowels /i/, /ê/, /a/ produced at normal, high, low and low-high-low pitch, and recordings of a German sentence | Se: 67.1% (MSCC), 56.25% (MFCC) Sp: 62.36% (MSCC), 46.90% (MFCC) UA: 64.75% (MSCC), 51.58% (MFCC) Accuracy: 63.67% (MSCC), 50.54% (MFCC) |

| Reference | Design (according to NIMRBC) | QualSyS (by Kmet et al) | Participants,* | Patients' age | Acoustic parameters (definitions) | Comparison criteria | Speech sample | Author(s) main conclusion(s) |
|-----------|-----------------------------|-------------------------|----------------|-------------|----------------------------------|--------------------|---------------|-----------------------------|
| Hu et al[11] | IB-2 | 20/22 | Participants: 13 patients (8 M, 5 F) with postpartial lateral glossectomy patients | Mean: 45.3 y | First three formants of the middle segment of vowels /i/ and /u/, automatically extracted by LPC | Measure: calculation of (F2/F1), (F3/F2), (F3/F1), and comparison with a control group of 23 normal controls | Vowels /i/ and /u/ from seven repetitions of “a geese” and “a souk” | MSCC parameters improved significantly in the classification rate between intelligible and not intelligible than the MFCC on both corpuses. |
| Jacobi et al[29] | IB-3 | 19/20 | Participants: 34 patients (27 M, 7 F) with advanced head and neck tumors treated by chemoradiotherapy | Median: 58 y | F1 and F2 on vowels /i/, /ʊ/, /u/ | Measure: pairwise comparisons between before and after treatment | Standard Dutch text Diadochokinesis (‘pataka’ repetition) List of words (DYVA) | 10 weeks after the end of treatment: Nasality: decrease compared to baseline (P = .06 and t = 1.935). Significant differences for /t/ (higher spectral burst frequency), /k/ (more diffuse), and /t/ productions (increase of F2 and F1) 1 y after the end of treatment, significant differences (P < .05) for /t/, /k/ (weaker), /l/ (significantly higher F3 with lower intensity), /s/ (lower frequency measures in initial and final position), /v/, /N/, /W/ |
| Kazi et al[30] | IB-2 | 20/20 | Participants: 26 patients (19 M, 7 F) with squamous cell carcinoma who underwent partial glossectomy | Mean: 53.1 y, SD 8.7 | F1, F2, and F3: averaged LPC coefficients (for an estimate for each speaker) | Measure: correlation of formant frequencies between 31 control subjects and patients' group | Sustained vowel /i/ produced at a comfortable pitch and loudness for at least 5 s | Significant formant correlations: • between normal and study females on F2 (P = .04) and F3 (P = .02) • between normal and study males on F3 (P = .01) No other significant formant correlations on other comparisons |
| Kim et al[31] | IB-3 | 19/22 | Participants: corpus NKI-CCRT (Clapham, 2012): 55 patients (45 M, 10 F) with head and neck cancer surgery and chemotherapy | Not reported (but reference to Van der Molen, 2009: mean 58 y, range 32-79) | MRSTC: multiresolution sinusoidal transform coding using wavelet-like analysis (lower frequency components calculated over a greater | Measure: Accuracy (ACC) defined as: (number of hits)/ (number of instances) | Reading a 189-word passage from a Dutch fairy tale | On binary intelligibility classifier: ACC: 68.0 (SVM), 72.7 (SVM + MRSTC) UWA: 66.2 (SVM), 71.2 (SVM + MRSTC) |
## APPENDIX A (Continued)

| Reference | Design (according to NHMRC) | QualSys by Kmet et al. | Participants, diagnosis, language | Patients' age | Acoustic parameters (definitions) | Comparison criteria | Speech sample | Author(s) main conclusion(s) |
|-----------|-----------------------------|------------------------|----------------------------------|---------------|----------------------------------|---------------------|--------------|-----------------------------|
| Knuuttila et al. | II-3 | 16/20 | Patients: 9 patients (8 M, 1 F) operated for tongue cancer | Range: 41-75 y | First (F1) and second (F2) formant estimated on a stable part of the sustained vowel (FFT analysis was used for spectral analyses) | Measure: differences in acoustic measurements of vowels after and before tongue resection (F1 and F2) | Sustained Finnish vowels produced twice | Significant difference only for F1 of /i/ (P = .03) and F2 of /a/ (P = .01). Higher F1 of /i/ (mean: 32, P = .05) and lower F2 of /a/ (mean: −97, P = .01) after surgery |
| Kraaijenga et al. | III-3 | 19/22 | Participants: 18 patients treated by concurrent chemoradiotherapy in two groups: NT group: six nasopharyngeal and tonsil tumors patients, LHBT group: 12 with laryngeal, hypopharyngeal and base of tongue tumors | Mean age: 63 y, range 45-79 | Nasality measured with the software Praat | Measure: comparison of antiformants between a baseline (postsurgery) and 2 y (Y + 2) and 6 y (Y + 6) post-treatment | Sustained /a/ | Improvements at Y + 2 and deterioration at Y + 6 in the “NT group.” Deterioration compared to baseline also in “LHBT group” (paired t test P = .09). |
| Kumar et al. | III-3 | 16/22 | Participants: 10 patients (9 M, 1 F) treated by maxillectomy | Mean: 43 y, range 15-75 | Nasalance measured by the nasal view of Dr. Speech software | Measure: automatic percentage of nasalance at different times (preoperative, at complete healing without obturator, and 24 h and 6 wk after placement of the obturator) | Phonation of a sustained vowel | Nasalance increases abruptly from 20.16 ± 5.52 to 52.04 ± 19.25 after surgery (P = .01) |
| Laaksonen et al. | III-3 | 21/22 | Participants: 17 patients (11 M, 6 F) with tongue cancer (anterior 2/3 of the tongue was reconstructed with a radial forearm free flap) | M: 53 y (mean), range 27-67; F: 59 y (mean), range 17-72 | Spectral moments (from spectrum computed from the waveform/spectrogram display using the FFT) of the LTA spectrum: mean (first moment), and skewness (third moment) | Measure: Comparison of the measurements produced before tongue resection, 1, 6, and 12 mo after reconstruction | Reading of six stimulus sentences and the Zoo passage: analyses of 892 tokens for /s, z/, and 88 tokens for /ʃ/ | Spectral mean: Reduction of acoustic distinctiveness between /s, z, /ʃ/ Decreased fast (preoperative vs 1-mo postoperative, P < .0001), mean difference: 1094 Hz and then increased (1-mo vs 6-mo postoperative, P < .0001, mean difference: 752 Hz) without returning to preoperative levels (preoperative vs 12-mo postoperative, P < .0001), mean difference: decreasing of 654 Hz. |

| Reference          | Design (according to NHMRC) | QualSyst (by Kmet et al) | Participants, diagnosis, language | Patients' age | Acoustic parameters (definitions) | Comparison criteria                                                                 | Speech sample                                                                 | Author(s) main conclusion(s) |
|--------------------|-----------------------------|--------------------------|----------------------------------|---------------|----------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------|------------------------------|
| Laakso nen et al   | III-3                       | 17/20                    | 85% (strong)                     | Range 27-72 y | F1, F2, F0, and duration were analyzed | Measure: Comparison of the parameters before the tongue resection and 1, 6, and 12 mo. after tongue reconstruction | Vowels /i/, /I/, /a/, and /u/ (chosen because of their articulatory, acoustical and perceptual distinctiveness) and diphthongs /ai/, /eI/ from a set of six sentences including [hVd] sequences (eg, "heed" or "who'd") | Females got back to the preoperative level gradually within 1 y period (preoperative vs 12-mo. postoperative, P < .0001, mean difference: 1142 Hz) |
| Verkkonen-Lepo et al | III-2                       | 22/22                    | 100% (strong)                    | Mean: 56.2 y, range 38-80 | Speech resonance is evaluated by nasalance (ie, objective and specific acoustic substitution of perceived nasality) with a Nasometer | Measure: Comparison of values before and after surgery (post 6 wk, 3 mo., 6 mo., 12 mo.) | Sentences loaded with voiceless plosive consonants or voiced consonants. Each sentence is repeated three times | For the male patient group, long-term effects were observed in F2 and in vowel duration. F2 decreased (interaction: F = 3.262, P = .002; preop. vs 12 mo. postop. [pairwise comparison] P = .003, mean difference 68 Hz). For the female patient group, no statistically significant changes were observed (all P values > .05) for any of the outcome measures. |
| Moerman et al      | IV-1                        | 14/22                    | 64% (good)                       | Not reported   | Nasalance measurement by nasometry | Measure: Comparison between mean nasalance scores | Reading of an oronasal, an oral, and a nasal text | Normal nasalance before and after operation in the OC patient group. In OP patients, however, nasalance increased after operation, differing significantly from OC patients at 6 wk and 6 mo. after surgery (P < .05) |
| Seikaly et al      | III-3                       | 17/20                    | 85% (strong)                     | Mean: 55.1 y (43-75) | Nasalance balance by nasometry assessed by Nasometer, PERCI-SARS and the Computerized Assessment of Intelligibility of Dysarthric Speech (CAIDS) | Measure: Comparison between mean nasalance scores at three times in point: before surgery, 1 mo. after surgery and pre-RT, and 6-9 mo. after surgery and completion of RT | Not reported | Preoperative nasalance values differed significantly from pre-RT time values (P = .05). Preoperative word intelligibility scores differed significantly from both pre-RT time (P < .01) and post-RT (P < .05). No significant differences for any of these variables between pre-RT time and post-RT time. |
| Reference          | Design (according to NHMRC) | Qualify (by Knesi et al) | Participants, diagnosis, language | Patients’ age | Acoustic parameters (definitions) | Comparison criteria | Speech sample | Author(s) main conclusion(s) |
|-------------------|-------------------------------|--------------------------|----------------------------------|---------------|----------------------------------|---------------------|--------------|-------------------------------|
| Takasu et al      | III-3                         | 10/20 95% (strong)       | Participants: 62 patients with tongue cancer; Group 1 (G1): 40 (29 M, 11 F) with partial glossectomy; T classification (T/N/M): T1 = 6, T2 = 6, T3 = 3, T4 = 7; Group 2 (G2): 22 (15 M, 7 F) reconstructed; T classification (T/N/M): T1 = 1, T2 = 4, T3 = 3, T4 = 14; Language: Japanese | G1: median 55.8 y, range 30-77 y | Formant frequency of vowels (center of 30-ms intervals of sustained vowels, excluding the first and last 25 ms): F1, F2, and slopes of formant transitions (formant slopes) between diphthongs /ui/ and /ai/ | Measure: Comparison of acoustic characteristics data collected during the preoperative and postoperative periods, and after rehabilitation | Sustained vowels: 3 s of /ai/, /ei/, /ui/ | Word repetition task: /taiko/, /kaiko/, /suika/ were sampled three times each. |
| Wakamato et al    | III-3                         | 14/20 95% (strong)       | Participants: 10 patients treated by glossectomy; Group 1 (G1): 5 directly sutured patients (4 M, 1 F); T classification (T/N/M): T1 = 1, T2 = 3, T3 = 4, T4 = 1; Group 2 (G2): 5 patients reconstructed with forearm flap (5 M); T classification (T/N/M): T1 = 1, T2 = 2, T3 = 2, T4 = 1; Language: Not reported | G1: median 37.4 y, range 28-67 y | Frequency characteristics at consonant section with the spectral envelope extracted by FFT from LPC coefficients: calculation of the formant frequency by peak picking method; CPF: physical evaluation score that aims to quantitatively evaluate the frequency characteristics at the consonant section | Measure: Comparison of the scores collected before operation, 1-, 6-, and 12-mo. post-surgery | Pronunciation of the target syllable /ai/, selected among speech intelligibility test samples because of its pronunciation with the front side closure of the OC using tongue tip | G1: Directly sutured subjects: CPF: some got lower scores preoperatively than at the postoperative sessions; F2-F3: some showed close to the baseline scores 1-mo. postoperation | G2: Reconstruction: CPF: some disclosed a concentration tendency approximately at the 3-5 kHz area 1-mo. postoperation; F2-F3: 1-mo. postoperation, some showed the scores close to the baseline |
| Yoshida et al     | III-3                         | 10/20 95% (strong)       | Participants: 15 patients (4 M, 11 F) treated for various types of palatal/maxillary or maxillary sinus cancers; T classification (T/N/M): not reported; Language: Not reported | Range 38-78 y | Spectral analyses on 1/3-octave spectra obtained from data transformed by FFT analysis and 1/3-octave band-pass filtered in the frequency range of 125 Hz to 6.3 kHz | Measure: 5-point scale assessment for hypernasality Rates: two speech pathologists | Sustained vowel /i/ during 0.5 s at an individually preferred pitch and loudness | Correlation: high correlation between the perceptual ratings and the predicted values (r = 0.8419, adjusted r² = 0.8147, F[2, 27] = 32.480, P < .001) by a stepwise regression (with the perceptive score as outcome, and F7 and F12, amplitudes of the 7th and 12th multiples in the normalized 1/3-octave spectra, as dependent variables) |

Abbreviations: ANN, artificial neural network; BT, base of tongue; COG, center of gravity; CPF, consonant peak energy frequency; FFT, fast Fourier transform; LHBT, laryngeal, hypopharyngeal, and base of tongue tumors; LPC, linear prediction coefficient; LTA, long time average; MFCC, mel-frequency cepstrum coefficients; MRSTC, multiresolution sinusoidal transform coding; MSCC, mel S-transform cepstrum coefficients; NT, nasopharynx or lateral pharyngeal wall or tonsil; OC, oral cavity; OP, oropharyngeal; RT, radiotherapy; SVD, Saarbruecken Voice Database; SVM, support vector machine; UA, under a curve area; VOT, voice onset time.

aNHRMC hierarchy: Level 1, systematic reviews; Level II, randomized control trials; Level III-1, pseudo-randomized control trials; Level III-2, comparative studies with concurrent controls and allocation not randomized (cohort studies), case control studies, or interrupted time series with a control group; Level III-3, comparative studies with historical control, two or more single-arm studies, or interrupted time series without a control group; Level IV, case series.

bMethodological quality: strong (>80%); good (60%-79%); adequate (50%-59%); and poor (<50%).

cM: males, F: females.
## APPENDIX B  ACOUSTIC PARAMETERS ANALYZED IN THE INCLUDED STUDIES

| Nasalance | Vowels | Consonants | Global speech |
|-----------|--------|------------|---------------|
| Dedicated software or nose-meters | Ratio of acoustic energy output of nasal nasal and oral cavity | F1 and F2 (±F3) | F1 to F12 | VSA | Transition slope | Spectral moments | Duration of air pressure release | Friction duration and the band energy | F1, F2, F3 on /l/ and /R/ | Feature extraction: MFCC, MSFCC, MRSTC, ANN-nasalance |
