Abstract

Aim of this work was to analyse some microbiological, chemico-physical and organoleptic parameters of sheep milk yogurt during and after its declared shelf-life. Five samples of a sheep’s milk yogurt of the same lot, collected from a short supply chain ovine dairy farm of the Roman province, were analysed. Declared shelf-life of the product was 30 days. The products were examined at 2, 14, 30, 35 and 40 days from the production date, performing the following microbiological analyses: enumeration of i) colony-forming units characteristic of the yogurt, ii) Enterobacteriaceae, iii) yeasts and/or moulds at 25°C. Microbiological identification was performed by miniaturized biochemical tests and for the lactic acid bacteria also by PCR. At every test interval, evaluation of organoleptic parameters and pH was also performed. The analysed product maintained an almost constant amount of lactic acid bacteria until the end of the declared shelf-life. Concerning lactic acid bacteria, a 100% concordance of the results observed by using biochemical identification methods and PCR assays was obtained. After 14 days from the production, the presence of yeasts (Candida famata) was revealed, while the presence of moulds was detected after 30 days. Ralstonia picketti, an environmental microorganism, was also isolated. The results obtained in this study indicate that yogurt spoilage is mainly due to the growth of specific microorganisms of spoilage, such as yeasts and moulds.

Introduction

Yogurt is a fermented milk product widely known and appreciated for its beneficial effects on consumers health. To obtain a first-rate yogurt, excellent quality raw materials and production techniques that follow the good manufacturing practices should be used. Yogurt is a perishable food due to its composition and physico-chemical properties. Its shelf-life could be established based on microbiological data and the use of other parameters such as sensory analysis, aw, pH and titratable acidity (Mataragas et al., 2011).

Chemico-physical and microbiological modifications of yogurt until the expiry date, which can vary from 20 to 40 days from the date of production, can cause undesired changes in the organoleptic properties of the product (colour, odour, flavour and texture). For this reason, correct storage conditions until the end of shelf life is essential for the maintenance of product characteristics. The alteration of dairy products such as yogurt is mainly linked to the development of specific spoilage organisms (SSOs) such as yeasts and moulds. The deterioration of yogurt by yeasts is generally identified by the development of abnormal flavours, yeast odour and CO₂ production with consequent swelling of the lid heat-sealed when used (Vallone et al., 2001). In absence of specific guidelines in the Italian legislation, some Authors report that yogurt cultures (Lactobacillus delbrueckii subsp. bulgaricus and Streptococcus thermophilus bacteria) should be alive and viable until the time of consumption and in quantities not less than 10⁶ CFU/g (Health Ministry, 1972).

The decrease in pH caused by the production of lactic acid is one of the desirable effects of the metabolic activity of lactic acid bacteria. In fact, the main benefits of yogurt are related to its acidity: the production of lactic acid from lactose can allow the consumption of this product also by lactose intolerant consumers; moreover, it promotes the absorption of calcium and minerals (Al-Kadamany et al., 2002; Mataragas et al., 2011). The analysis of the aspects described above is essential to determine the conditions of conservation and define the length of shelf-life period of yogurt.

The aim of this work was to analyse some microbiological, chemico-physical and organoleptic parameters in samples of sheep milk yogurt produced in a short supply chain farm, during the shelf-life declared by the dairy farmer.

Materials and Methods

Five samples of a sheep milk yogurt of the same lot, collected from a short supply chain ovine dairy farm of the Roman province, were analysed. Declared shelf-life of the product was 30 days. The yogurts stored at 4°C were examined in 5 sessions of analysis: at 2, 14, 30, 35 and 40 days from the production date.

The following microbiological analysis were performed: enumeration of characteristic microorganisms of yogurt (ISO 7889:2003; ISO, 2003a), identification of Lactobacillus delbrueckii bulgaricus and Streptococcus thermophilus (ISO 9232:2003; ISO, 2003b), enumeration of Enterobacteriaceae (ISO 21528-2: 2004; ISO, 2004a), enumeration of yeasts and moulds at 25°C (ISO 6611:2004; ISO, 2004b).

The identification of the isolated microorganisms was performed using miniaturised biochemical tests (API CHL Biomerieux®, API C AUX Biomerieux® and API NE Biomerieux®; bioMérieux, Mary l’Étoile, France). The identity of lactic acid bacteria was also verified by PCR analysis. DNA was extracted from bacterial colonies by using boiling method and subjected to PCR using primers and reaction conditions reported in the literature for the identification of Streptococcus thermophilus (Fortina et al., 2003), Lactobacillus delbrueckii subsp. bulgaricus and subsp. lactis (Torriani et al., 1999), and a GeneAmp® PCR System 9700 (Applied Biosystems, Carlsbad, CA, USA) machine.

Amplified products were visualised on 1.2% agarose gel containing Gel Red® in Tris-acetate-EDTA 1X by using a UV-transilluminator. In each analysis session, the organoleptic acceptability of each sample was evaluated by criteria such as discouloration, mould formation, off-odours, abnormal flavours and texture. The pH of each sample was measured with a MP225 pH meter (Mettler Toledo Inc., Leicester, UK) with a probe for the detection of the temperature and electrode combined as
follows: once the sample reached 25°C, the determination of pH was performed repeating the measurements in duplicate for each sample. The same analyses were also performed on a single sample of bulk milk collected from the same farm.

Results

The analysed product maintained an almost constant amount of lactic acid streptococci (on the order of $10^9$ CFU/g) until the end of the declared shelf-life (Figure 1). The concentration of lactobacilli remained almost constant until the end of shelf-life (with a concentration on the order of $10^8$ CFU/g), followed by a slight decrease after the expiry date (Figure 1).

Concerning lactic acid bacteria, on the totality of the bacterial strains identified as Lactobacillus delbrueckii subsp. bulgaricus and Streptococcus thermophilus, there was a 100% concordance of results by using biochemical and PCR methods. The concentration of enterobacteria was found to be <10 CFU/g in all samples. The presence of yeasts was detected starting from 14 days after production, with a concentration of 40 CFU/g; during the subsequent analyses they increased, until a concentration of $10^3$ CFU/g at the end of the shelf-life. The result of the yeast typing on the isolates revealed the presence of Candida famata species only. The presence of moulds was observed starting from 30 days of production (expiry date of the product) at a concentration of $4.3\times10^3$ CFU/g. Overall, the microbiological analyses performed during the shelf-life period revealed a modest increase of undesirable microorganisms such as yeasts and moulds, with a constant concentration or a slight decrease in lactic acid bacteria. From the examined yogurts and from the bulk milk sample as well, the presence of Ralstonia pickettii, i.e. a contaminating microorganism probably of environmental origin, was detected.

The organoleptic characteristics of the products remained unchanged until the end of the declared shelf-life. Therefore, the presence of yeasts and moulds produced no substantial organoleptic variations up to 30 days from the production date. However, a bitter/cheese flavour and an acrid smell was perceived in the yogurts after the expiry date of the product.

The pH values measured from the examined yogurts showed minimal variations until the end of the shelf-life (from 4.56 to 4.61), while a decrease (until 4.35) occurred after the end of shelf-life (Figure 2).

Discussion

As reported in the literature, our results showed that the process of deterioration in yogurt is due primarily to the development of SSOs, such as yeasts and moulds; these organisms are able to ferment lactose and sucrose also at refrigeration temperatures and low pH values. The presence of these organisms can be determined by: addition of characterising ingredients, such as cereals, fruit not properly pasteurised; application of improper production and/or storage practices; use of inadequate raw materials. In this case, it is important to evaluate the starting microbiological quality of the milk (Mataragas et al., 2011). Only in very few cases the source of contamination of yogurt are the starter cultures; thus, a correct monitoring of the production and storage areas of the products is pivotal.

Conclusions

Research to identify the origin of the contamination by Ralstonia pickettii are still ongoing. Good sensory characteristics and an almost constant concentration of lactic acid bacteria were maintained during all the commercial life of the products. However, the study of contaminating microorganisms detected could be of a certain relevance. Predictive models might be useful to study the process of deterioration of yogurts by contaminants. Such information could be extremely relevant for dairy farmers to determine a suitable shelf-life of their products (Al-Kadamany et al., 2002; Mataragas et al., 2011; Sofu and Evinci, 2007). In order to evaluate meaningfully chemical-physical and microbiological modifications during the shelf-life period of this product, it could be helpful to extend the number of samples.
