Spectral Determinants on Mandelstam Diagrams

Luc Hillairet, Victor Kalvin, Alexey Kokotov

December 3, 2013

Abstract. We study the regularized determinant of the Laplacian as a functional on the space of Mandelstam diagrams (noncompact translation surfaces glued from finite and semi-infinite cylinders). A Mandelstam diagram can be considered as a compact Riemann surface equipped with a conformal flat singular metric $|ω|^2$, where $ω$ is a meromorphic one-form with simple poles such that all its periods are pure imaginary and all its residues are real. The main result is an explicit formula for the determinant of the Laplacian in terms of the basic objects on the underlying Riemann surface (the prime form, theta-functions, canonical meromorphic bidifferential) and the divisor of the meromorphic form $ω$. As an important intermediate result we prove a decomposition formula of the type of Burghelea-Friedlander-Kappeler for the determinant of the Laplacian for flat surfaces with cylindrical ends and conical singularities.

1 Introduction

Formally, a (planar) Mandelstam diagram is a strip $Π = \{z ∈ \mathbb{C} : 0 ≤ \Im z ≤ H\}$ with finite number of slits parallel to the real line. These slits are either finite segments or half-lines, the sides of different slits and parts of the boundary of the strip are glued together according to a certain gluing scheme. This gives a surface made from a finite number of finite and semi-infinite cylinders. In addition, the diagram could be twisted via cutting the finite ("interior") cylinders into two parts by vertical cuts and gluing these parts back with certain twists; see, e. g., [11], [12] for more details, explanation of the terminology and proper references to the original physical literature.

One thus obtains a noncompact translation surface $M$ or, more precisely, a flat surface with trivial holonomy with conical singularities (at the end points of the slits) and cylindrical ends.

One can also consider $M$ as a compact Riemann surface (i. e. an algebraic curve) with flat conformal metric $|ω|^2$, where $ω$ is the meromorphic differential on $M$ obtained from the 1-form $dz$ in a small neighborhood of a nonsingular point of $M$ via parallel transport. The differential $ω$ has zeros at the end points of the slits and the first order poles at the points of infinity of cylindrical ends. All the periods of $ω$ are pure imaginary,
all the residues at the poles of $\omega$ are real.

Moving in the opposite direction, one can get a Mandelstam diagram from a Riemann surface and a meromorphic differential with pure imaginary periods and simple poles with real residues. More precisely, let $X$ be a compact Riemann surface of genus $g$ with $n \geq 2$ marked points $P_1, \ldots, P_n$ and let $\alpha_1, \ldots, \alpha_n$ be nonzero real numbers such that $\alpha_1 + \cdots + \alpha_n = 0$. Then there exists a unique meromorphic differential $\omega$ on $X$ with simple poles at $P_1, \ldots, P_n$ such that all the periods of $\omega$ are pure imaginary and $\text{Res}(\omega, P_k) = \alpha_k$, $k = 1, \ldots, n$. Moreover, to such a pair $(X, \omega)$ there corresponds a Mandelstam diagram (with $n$ semi-infinite cylinders) (see [11]).

The space of Mandelstam diagrams with fixed residues $\alpha_1, \ldots, \alpha_n$ (i.e. with fixed circumferences, $|O_1|, \ldots, |O_n|$ of the cylindrical ends) is coordinatized by the circumferences, $h_i$, of the interior cylinders; the interaction times $\tau_j$ (see [11] for explanation of the terminology) – the real parts of the $z$-coordinates of the zeros of the differential $\omega$ (we assume that the smallest interaction time, $\tau_0$, is equal to 0, this can be achieved using a horizontal shift of the diagram) and the twist angles $\theta_k$.

Mandelstam diagrams (with fixed residues $\alpha_1, \ldots, \alpha_n$) give a cell decomposition of the moduli space $M_{g,n}$ of compact Riemann surfaces of genus $g$ with $n$ marked points. The top-dimensional cell is given by the set $S_{g,n}$ of simple Mandelstam diagrams, for these diagrams the corresponding meromorphic differential $\omega$ has only simple zeros. The parameters

$$h_i, \quad i = 1, \ldots, g; \quad \tau_j, \quad j = 1, \ldots, 2g + n - 3; \quad \theta_k, \quad k = 1, \ldots, 3g + n - 3 \quad (1.1)$$

give global coordinates on $S_{g,n}$, see Fig. [11] taken from [12], p. 93) for the case $g = 2, n = 4$, three poles with negative residues, one pole with positive residue.

From now on we refer to the coordinates (1.1) as moduli.

The goal of the present paper is to study the regularized determinant of the Laplacian on a noncompact translation surface $M$ as a function of moduli (for simplicity we consider only the top dimensional cell). The title of the paper is chosen to emphasize the relation to older paper [6] (see also [35]) where such a determinant was defined in a heuristic way (unrelated to the spectral theory) and the question of the possibility of a spectral definition was raised. It should be said that in contrast to [6] we are working here with scalar Laplacians, the Laplacians acting on spinors will be considered elsewhere.

The scheme of the work can be briefly explained as follows. Assume for simplicity that a Mandelstam diagram $M$ has two cylindrical ends. Then the Laplacian $\Delta$ on

![Figure 1: Mandelstam Diagram.](image_url)
\( \mathcal{M} \) can be considered as a perturbation of the "free" Laplacian \( \hat{\Delta} \) on the flat infinite cylinder \( S^1(\frac{dH}{\pi}) \times \mathbb{R} \) obtained from the strip \( \Pi \) via identifying the points \( x \in \mathbb{R} \) with points \( x + iH \in \mathbb{R} + iH \). Then, following the well-known idea (see, e.g., [29], [15], [2]), one can introduce the relative operator zeta-function

\[
\zeta(s; \Delta, \hat{\Delta}) = \frac{1}{\Gamma(s)} \int_0^\infty \text{Tr}(e^{-t\Delta} - e^{-t\hat{\Delta}}) t^{s-1} dt \tag{1.2}
\]

and define the relative zeta-regularized determinant of the operator \( \Delta \) (having continuous spectrum, possibly with embedded eigenvalues - see an example in Appendix A.2) via

\[
\det(\Delta, \hat{\Delta}) := e^{-\zeta'(0; \Delta, \hat{\Delta})}. \tag{1.3}
\]

In case of \( n \geq 3 \) cylindrical ends the definition of \( \det(\Delta, \hat{\Delta}) \) is similar: as the free Laplacian \( \hat{\Delta} \) one takes the Laplacian on the diagram with \( n \) semi-infinite slits starting at \( \tau_0 = 0 \) (a sphere with \( n \) cylindrical ends).

Our main result is an explicit formula for \( \det(\Delta, \hat{\Delta}) \) in terms of classical objects on the Riemann surface \( \mathcal{M} \) (theta-functions, the prime form, the Bergman kernel) and the divisor of the meromorphic differential \( \omega \).

At the first step we establish variational formulas for \( \log \det(\Delta, \hat{\Delta}) \) with respect to moduli. At the second step we integrate the resulting system of PDE and get an explicit expression for \( \det(\Delta, \hat{\Delta}) \) (up to moduli independent constant). The derivation of the above mentioned variational formulas goes as follows.

First we prove a decomposition formula of the Burghelea-Friedlander-Kappeler type for \( \det(\Delta, \hat{\Delta}) \). This formula could not be considered as a completely new one: for smooth manifolds with cylindrical ends analogous formulas were found in [26] and [31]. We believe that it would be possible to establish our result just following the way of [26] or [31] with suitable modifications: presence of conical points and slightly different method of regularization (in [26] and [31] the authors use the operators of Dirichlet problem in semi-cylinders as "free", whereas we are using here for that purpose the Laplace operator in the infinite cylinder), should not present a serious additional difficulty. The proofs from [31] are based on the one hand on results from scattering theory on manifolds with cylindrical ends that themselves depend on techniques of Melrose [27] and on the other hand from results of Carron [2].

We have chosen here a slightly different approach that avoids the full machinery of scattering theory on manifolds with cylindrical ends (see [27, 4, 5]). Following [2], it is fairly straightforward to get a gluing formula for non-zero values of the spectral parameter so that the only missing ingredient is a precise description of the resolvent of the operator \( \Delta \) at the bottom of its continuous spectrum (see Theorem 2 below). The latter can then be obtained using methods of elliptic boundary value problems.

Using the decomposition formula, we reduce the derivation of the variational formulas for \( \det \Delta \) to a simpler case of Laplacians (with discrete spectra) on \emph{compact} conical surfaces which are flat everywhere except standard fixed "round" ends. After that, using a certain version of the classical Hadamard formula for the variation of the Green function of a plane domain (see Proposition 2), we derive the variational formulas for the latter simpler case.

The resulting system of PDE for \( \log \det \Delta \) (where the so-called Bergman projective connection is the main ingredient) is a complete analog of the governing equations for the Bergman tau-functions on the Hurwitz spaces and moduli spaces of holomorphic
differentials ([23], [21], [22]). Relying on the results obtained in [22, 23], it is not hard to propose an explicit formula for the solution of this system (its main ingredient, the Bergman tau-function on the space of meromorphic differentials of the third kind, was recently introduced by C. Kalla and D. Korotkin in [17]).

The proof of the thus conjectured formula is a direct calculation (similar to that from [22]). For the sake of simplicity we present this calculation for genus one Mandelstam diagrams only.

Acknowledgement. The work of AK was supported by NSERC. The work of LH is partly supported by the ANR programs METHCHAOS and NOSEVOL. The authors thank D. Korotkin for extremely useful discussions. We thank also C. Kalla and D. Korotkin for communicating the results from [17] long before their publication.

2 Relative determinant and decomposition formula

Consider \( M \) as a noncompact flat surface with cylindrical ends and conical points at the ends of the slits of \( \Pi = \{ z \in \mathbb{C} : 0 \leq \Im z \leq 1 \} \). We shall use \( x = \Re z \) as a (global) coordinate on \( M \). Let \( P \) be the set of all conical points on \( M \). Assume that \( R > 0 \) is so large that there are no points in \( P \) with coordinate \( x / R \in (-R, R) \). Denote \( \Gamma = \{ p \in M : |x| = R \} \) and consider the (positive) selfadjoint Friedrichs extension \( \Delta_{D}^{in} \) of the Dirichlet Laplacian on \( M_{in} = \{ p \in M : |x| \leq R \} \) with Dirichlet conditions on \( \Gamma \). Then for any \( f \in C^{\infty}(\Gamma) \) the Dirichlet problem

\[
\Delta u = 0 \text{ on } M \setminus \Gamma, \quad u = f \text{ on } \Gamma
\]

has a unique bounded at infinity solution \( u \) such that \( u = \tilde{f} - (\Delta_{D}^{in})^{-1} \Delta \tilde{f} \) on \( M_{in} \), where \( \tilde{f} \in C^{\infty}(M_{in} \setminus P) \) is an extension of \( f \). Introduce the Dirichlet-to-Neumann operator

\[
Nf = \lim_{x \to R^{+}} \langle -\partial_{x}u(-x), \partial_{x}u(x) \rangle + \lim_{x \to R^{-}} \langle \partial_{x}u(-x), -\partial_{x}u(x) \rangle,
\]

where \( \langle \cdot, \cdot \rangle \in L^{2}(\Gamma_{-}) \oplus L^{2}(\Gamma_{+}) \equiv L^{2}(\Gamma) \) with \( \Gamma_{\pm} = \{ p \in M : x = \pm R \} \). The operator \( N \) is a first order elliptic operator on \( \Gamma \) which has zero as an eigenvalue. The modified zeta regularized determinant \( \det^{*}N \) (i.e. the zeta regularized determinant with zero eigenvalue excluded) is well-defined. By \( \det \Delta_{D}^{in} \) we denote the zeta regularized determinant of \( \Delta_{D}^{in} \). In this section we prove

**Theorem 1.** The decomposition formula

\[
\det(\Delta, \tilde{\Delta}) = C \det^{*}N \cdot \det \Delta_{D}^{in}
\]

is valid, where \( N, \Delta_{D}^{in}, \) and \( C \) depend on \( R \), however \( C \) is moduli (that is \( h, \theta, \tau \)) independent.

As it was mentioned in the Introduction this theorem can be considered as a version of the analogous results from [26] and [31] for smooth manifold with cylindrical ends. However, we choose here a different less technical approach that avoids the full machinery of b-calculus [27] heavily used in [26] as well as spectral representations and elements of the scattering theory on manifolds with cylindrical ends [14, 9, 30] used in [31]; note that similar spectral representations and results of the scattering theory are also a part of results [27] used in [26] (for results of the scattering theory on manifolds with cylindrical ends see also [4, 5, 32]).
As in [31] our starting point is the Burghelea-Friedlander-Kappeler type decomposition of \( \det(\Delta - \lambda, \Delta - \lambda) \), obtained in [2] for negative (regular) values of the spectral parameter \( \lambda \). (Although only smooth manifolds are considered in [2], it is fairly straightforward to see that on Mandelstam diagrams the decomposition remains valid outside of conical points.) In order to justify the decomposition for \( \det(\Delta, \Delta) \) (i.e. at the bottom \( \lambda = 0 \) of the continuous spectrum of \( \Delta \) and \( \Delta \)), one has to study the behavior of all ingredients of the decomposition formula as \( \lambda \to 0- \) (i.e. zeta regularized determinants of Laplacians and Dirichlet-to-Neumann operators) and then pass to the limit. Our approach relies on precise information on the behavior of the resolvent of the operator \( \Delta \) at \( \lambda = 0 \) (see Theorem 2 below) obtained by well-known methods of elliptic boundary value problems and the Gohberg-Sigal theory of Fredholm holomorphic functions; see e.g. [25] [19] [20] and [13] (or e.g. [20] Appendix). As a consequence, we immediately get precise information on the behavior of the Dirichlet-to-Neumann operator and an asymptotic of its determinant as \( \lambda \to 0 \). The latter one also provides the integrand in (122) with asymptotic as \( t \to +\infty \). This together with asymptotic of the integrand as \( t \to 0 \) (obtained in a standard way) prescribes the behavior of \( \det(\Delta - \lambda, \Delta - \lambda) \) as \( \lambda \to 0- \) and completes justification of the decomposition formula for \( \det(\Delta, \Delta) \).

### 2.1 Resolvent meromorphic continuation and its singular part at zero

In this subsection we operate with Friedrichs extensions \( \Delta_\epsilon \) of the Laplacian \( \Delta \) in weighted spaces \( L^2_\epsilon(\mathcal{M}) \) with different values of weight parameter \( \epsilon \). For this reason we reserve the notation \( \Delta_0 \) for the (selfadjoint nonnegative) Friedrichs extension of the Laplacian \( \Delta \) in \( L^2(\mathcal{M}) \) initially defined on the set \( C^\infty_0(\mathcal{M} \setminus \mathcal{P}) \) of smooth compactly supported functions.

**Theorem 2.** By \( \mathcal{B}(L^2_\epsilon(\mathcal{M}), L^2_\epsilon(\mathcal{M})) \), \( \epsilon > 0 \), we denote the space of bounded operators acting from smaller \( L^2_\epsilon(\mathcal{M}) \) to bigger \( L^2_\epsilon(\mathcal{M}) \) weighted space with the norm \( \|u; L^2_\epsilon(\mathcal{M})\| = \|e_\gamma u; L^2(\mathcal{M})\| \), where the weight \( e_\gamma \in C^\infty(\mathbb{R}) \) is a positive function such that \( e_\gamma(x) = \exp(\gamma|x|) \) for all sufficiently large values of \( |x| \).

Let \( \epsilon \) be a sufficiently small positive number. Then the function

\[
\mu \mapsto (\Delta_0 - \mu^2)^{-1} - \frac{i}{2\mu} (1)_{L^2(\mathcal{M})} \in \mathcal{B}(L^2_\epsilon(\mathcal{M}), L^2_\epsilon(\mathcal{M}))
\]

is holomorphic in the union \( \mathbb{C}^+ \) of \( \mathbb{C}^+ = \{ \mu \in \mathbb{C} : \Re(\mu) > 0 \} \) with the disc \( |\mu| < 1 \). In other words, the resolvent \( (\Delta_0 - \mu^2)^{-1} \) viewed as the holomorphic function

\[
\mathbb{C}^+ \ni \mu \mapsto (\Delta_0 - \mu^2)^{-1} \in \mathcal{B}(L^2_\epsilon(\mathcal{M}), L^2_\epsilon(\mathcal{M}))
\]

has a meromorphic continuation to \( \mathbb{C}^+_\epsilon \) which is holomorphic in \( \mathbb{C}^+_\epsilon \setminus \{0\} \) and has a simple pole at zero with the rank one operator \( L^2_\epsilon(\mathcal{M}) \ni f \mapsto \frac{i}{2}(f, 1)_{L^2(\mathcal{M})} \in L^2_\epsilon(\mathcal{M}) \) as the residue.

The scheme of the proof can be described as follows. We consider the Friedrichs m-sectorial extension \( \Delta_\epsilon \) of the Laplacian \( \Delta \) initially defined on \( C^\infty_0(\mathcal{M} \setminus \mathcal{P}) \) and acting in the weighted space \( L^2_\epsilon(\mathcal{M}) \). (Here m-sectorial means that the numerical range \( \{(e_\epsilon \Delta_\epsilon u, u)_{L^2(\mathcal{M})} : u \in \mathcal{D}_\epsilon \} \subseteq \mathbb{C} : u \in \mathcal{D}_\epsilon \) and the spectrum of a closed operator \( \Delta_\epsilon \) in \( L^2_\epsilon(\mathcal{M}) \) with the domain \( \mathcal{D}_\epsilon \) are both in some sector \( \{ \lambda \in \mathbb{C} : |\arg(\lambda + c)| \leq \theta < \pi/2, c > 0 \} \). Then we introduce a certain rank \( n \) extension of the operator \( \Delta_\epsilon - \mu^2 \) (\( n \) stands for the number of cylindrical ends on \( \mathcal{M} \)). The inverse of that extension provides the resolvent
\( (\Delta_0 - \mu^2)^{-1} \) with the desired meromorphic continuation to \( \mathbb{C}_+^\ast \). The proof of Theorem \( \square \) is preceded by Lemmas \( \square \) \( \square \) and Proposition \( \square \)

In order to introduce \( \Delta_\epsilon \) we need to obtain some estimates on the quadratic form

\[
q_\epsilon[u,u] = \|\nabla u; L^2_\epsilon(M)\|^2 + ((\partial_x e_{2\epsilon})(\partial_x u), u)_{L^2(M)}, \quad u \in C_0^\infty(M \setminus \mathcal{P}),
\]

of the Laplacian \( \Delta \) in \( L^2_\epsilon(M) \). Denote by \( H^1_\epsilon(M) \) the weighted Sobolev space of functions \( v = e^{-\epsilon}u, \ u \in H^1(M) \), with the norm \( \|v; H^1_\epsilon(M)\| = \|e^{-\epsilon}v; H^1(M)\| \); here \( H^1(M) \) is the completion of the set \( C_0^\infty(M \setminus \mathcal{P}) \) in the norm

\[
\|u; H^1(M)\| = \sqrt{\|u; L^2(M)\|^2 + \|\nabla u; L^2(M)\|^2}.
\]

Clearly, \( |\partial_x e_{2\epsilon}(x)| \leq C e_{2\epsilon}(x) \),

\[
|((\partial_x e_{2\epsilon})(\partial_x u), u)_{L^2(M)}| \leq C\|\partial_x u; L^2_\epsilon(M)\| \cdot \|u; L^2_\epsilon(M)\|
\leq C^2 \delta^{-1} \|u; L^2_\epsilon(M)\|^2 + \delta \|\nabla u; L^2_\epsilon(M)\|^2, \quad \delta > 0,
\]

and the norm in \( H^1_\epsilon(M) \) is equivalent to the norm \( \sqrt{\|u; L^2_\epsilon(M)\|^2 + \|\nabla u; L^2_\epsilon(M)\|^2} \). Thus for some \( \delta > 0 \) and \( \gamma > 0 \) we obtain

\[
|\arg(q_\epsilon[u,u] + \gamma\|u; L^2_\epsilon(M)\|^2)| \leq \vartheta < \pi/2,
\]

\[
\delta\|u; H^1_\epsilon(M)\|^2 - \gamma\|u; L^2_\epsilon(M)\|^2 \leq \Re q_\epsilon[u,u] \leq \delta^{-1}\|u; H^1_\epsilon(M)\|^2,
\]

which shows that \( q_\epsilon \) with domain \( H^1_\epsilon(M) \) is a closed densely defined sectorial form in \( L^2_\epsilon(M) \). Therefore this form uniquely determines an \( m \)-sectorial operator \( \Delta_\epsilon \) (the Friedrichs extension of the Laplacian \( \Delta : C_0^\infty(M \setminus \mathcal{P}) \to L^2_\epsilon(M) \), see [18, Theorem VI.2.1]) possessing the properties: i) The domain \( \mathcal{D}_\epsilon \) of \( \Delta_\epsilon \) is dense in \( H^1_\epsilon(M) \); ii) For all \( u \in \mathcal{D}_\epsilon \) and \( v \in H^1_\epsilon(M) \) we have \( (e_{2\epsilon}\Delta_\epsilon u, v)_{L^2(M)} = q_\epsilon[u,v] \). This extension scheme also gives the nonnegative selfadjoint Friedrichs extension \( \Delta_0 \) if we formally set \( \epsilon = 0 \); the operator \( \Delta_\epsilon \) (with \( \epsilon > 0 \)) is non-selfadjoint. Due to conical points on \( M \) the second derivatives of \( u \in \mathcal{D}_\epsilon \) are not necessarily in \( L^2_\epsilon(M) \), e.g. [20].

**Lemma 1.** Equip the domain \( \mathcal{D}_\epsilon \) of \( \Delta_\epsilon \) with the graph norm

\[
\|u; \mathcal{D}_\epsilon\| = \sqrt{\|u; L^2_\epsilon(M)\|^2 + \|\Delta_\epsilon u; L^2_\epsilon(M)\|^2}.
\]

Then the continuous operator

\[
\Delta_\epsilon - \mu^2 : \mathcal{D}_\epsilon \to L^2_\epsilon(M)
\]

is Fredholm (or, equivalently, \( \mu^2 \) is not in the essential spectrum of \( \Delta_\epsilon \)) if and only if for any \( \xi \in \mathbb{R} \) the point \( \mu^2 - (\xi + i\epsilon)^2 \) is not in the spectrum \( \{0, 4\pi^2\ell^2|O_k|^{-2} : \ell \in \mathbb{N}, 1 \leq k \leq n\} \) of the selfadjoint Laplacian on the union of circles \( O_1, \ldots, O_n \). The essential spectrum of \( \Delta_\epsilon \) is depicted on Fig. \( \square \)

**Proof.** See Appendix. \( \square \)
Proof. We shall also use the operator $J$ which depend on $\mu$ and $|\mu|$. Considering the values of $\Delta \psi$ for $\mu \neq 0$, we have:

$$\sum_{k=1}^{n} c_k \varphi_k(\mu) \in D_\epsilon.$$

Lemma 2. Take some functions $C \ni \mu \mapsto \varphi_k(\mu) \in C^\infty(M \setminus P)$ satisfying

$$\varphi_k(\mu; p) = \begin{cases} e^{i\mu|x|}, & p = (x, y) \in (-\infty, -R-1) \times O_k \ (\text{resp. } p \in (R+1, \infty) \times O_k), \\ 0, & p \in M \setminus (-\infty, -R) \times O_k \ (\text{resp. } p \in M \setminus (R, \infty) \times O_k), \end{cases}$$

(2.4)

if $O_k$ corresponds to a cylindrical end directed to the left (resp. to the right). Let $\mu \in \mathbb{C}^+ \cap |\mu| < \epsilon$, where $\epsilon > 0$ is sufficiently small. Then for any $f \in L^2_\epsilon(M)$ and some $c_k \in \mathbb{C}$, which depend on $\mu$ and $f$, we have:

$$(\Delta_0 - \mu^2)^{-1} f - \sum_{k=1}^{n} c_k \varphi_k(\mu) \in D_\epsilon.$$  

(2.5)

Proof. See Appendix. 

Clearly, $(\Delta - \mu^2) \varphi_k(\mu) \in C^\infty_0(M \setminus P) \subset L^2(M)$. Thus Lemma 2.5 implies that the linear combinations of $\varphi_1(\mu), \ldots, \varphi_n(\mu)$ are asymptotics of $(\Delta_0 - \mu^2)^{-1} f$ as $|x| \to \infty$ with a remainder in the space $D_\epsilon$ of functions exponentially decaying at infinity. We introduce a rank $n$ extension $A(\mu) : D_\epsilon \times \mathbb{C}^n \to L^2_\epsilon(M)$ of the m-sectorial operator $\Delta_\epsilon - \mu^2$ by considering the values of $\Delta - \mu^2$ not only on $D_\epsilon$ but also on the asymptotics $\sum c_k \varphi_k(\mu)$. The continuous operator $A(\mu)$ acts by the formula

$$D_\epsilon \times \mathbb{C}^n \ni (u, c) \mapsto A(\mu)(u, c) = (\Delta_\epsilon - \mu^2) u + \sum_{k=1}^{n} c_k (\Delta - \mu^2) \varphi_k(\mu) \in L^2_\epsilon(M).$$

(2.6)

We shall also use the operator $\mathcal{J}(\mu)$ mapping $D_\epsilon \times \mathbb{C}^n$ into $L^2_{-\epsilon}(M)$ in the following natural way:

$$D_\epsilon \times \mathbb{C}^n \ni (u, c) \mapsto \mathcal{J}(\mu)(u, c) = u + \sum_{k=1}^{n} c_k \varphi_k(\mu) \in L^2_{-\epsilon}(M), \quad |\mu| < \epsilon.$$

The functions $\varphi_k(\mu)$, $1 \leq k \leq n$, are linearly independent and for $|\mu| < \epsilon$ we have $\varphi_k(\mu) \notin D_\epsilon$. Hence $\mathcal{J}(\mu)$ yields an isomorphism between $D_\epsilon \times \mathbb{C}^n$ and its range $\{u + \sum c_k \varphi_k(\mu) : u \in D_\epsilon, c \in \mathbb{C}^n\} \subset L^2_{-\epsilon}(M)$.
Below we will rely on some results of the theory of Fredholm holomorphic functions, see e.g. [13] or [19, Appendix A]. Recall that holomorphic in a domain $\Omega$ operator function $\mu \mapsto F(\mu) \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$, where $\mathcal{X}$ and $\mathcal{Y}$ are some Banach spaces, is called Fredholm if the operator $F(\mu) : \mathcal{X} \to \mathcal{Y}$ is Fredholm for all $\mu \in \Omega$ and $F(\mu)$ is invertible for at least one value of $\mu$. The spectrum of a Fredholm holomorphic function $F$ (which is the subset of $\Omega$, where $F(\mu)$ is not invertible) consists of isolated eigenvalues of finite algebraic multiplicity. Let $\psi_0$ be an eigenvector corresponding to an eigenvalue $\mu_0$ of $F$ (i.e. $\psi_0 \in \ker F(\mu_0) \setminus \{0\}$). The elements $\psi_1, \ldots, \psi_{m-1}$ in $\mathcal{X}$ are called generalized eigenvectors if they satisfy $\sum_{j=0}^{t} \frac{1}{j!} \partial_\mu^j F(\mu_0) \psi_{t-j} = 0$, $t = 1, \ldots, m - 1$. If there are no generalized eigenvectors and $\dim \ker F(\mu_0) = 1$, we say that $\mu_0$ is a simple eigenvalue of $F$. Let $\mu_0$ be a simple eigenvalue of a Fredholm holomorphic function $F$. Then in a neighborhood of $\mu_0$ the inverse $F(\mu)^{-1}$ of the operator $F(\mu)$ admits the representation

$$F(\mu)^{-1} = \frac{\omega_0(\cdot)}{\mu - \mu_0} + H(\mu), \quad (2.7)$$

where $\mu \mapsto H(\mu) \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$ is holomorphic, $\psi_0 \in \ker F(\mu_0) \setminus \{0\}$, and $\omega_0 \in \ker F^*(\mu_0)$ is an eigenvector of the adjoint holomorphic function $\mu \mapsto F^*(\mu) = (F(\mu))^* \in \mathcal{B}(\mathcal{Y}^*, \mathcal{X}^*)$ such that the value of the functional $\omega_0(\cdot)$ on $\partial_\mu F(\mu_0) \psi_0$ is 1. Note that the converse is also true, i.e. $(2.7)$ implies that $\mu_0$ is a simple eigenvalue of $F$ and $\psi_0 \in \ker F(\mu_0)$. For the proof of $(2.7)$ we refer to [13, Theorem 7.1] and [19, Theorem A.10.2].

**Proposition 1.** Let $\epsilon > 0$ be sufficiently small. Then

1. $\mu \mapsto A(\mu) \in \mathcal{B}(\mathcal{D}_\epsilon \times \mathbb{C}^n, L^2(\mathcal{M}))$ is a Fredholm holomorphic operator function in the disc $|\mu| < \epsilon$ and $A(\mu)$ is invertible for all $\mu \in \mathbb{C}^+$. 
2. $\ker A(0) = \{\mathcal{B}(0)^{-1} C : C \in \mathbb{C}\}$ and $\ker A(0)^* = \{e_{-2} C : C \in \mathbb{C}\}$.
3. There are no solutions $(v, d)$ to the equation $(\partial_\mu A(0))(\mathcal{B}(0))^{-1} + A_0(v, d) = 0$, i.e. there are no generalized eigenvectors and $\mu = 0$ is a simple eigenvalue of $A(\mu)$.
4. In the disc $|\mu| < \epsilon$ we have

$$A(\mu)^{-1} = \frac{i}{2\mu}(1, \mathcal{J}(0)L^2(\mathcal{M}))\mathcal{J}(0)^{-1}1 + \mathcal{H}(\mu),$$

where $\mu \mapsto \mathcal{H}(\mu) \in \mathcal{B}(L^2(\mathcal{M}), \mathcal{D}_\epsilon \times \mathbb{C}^n)$ is holomorphic.
5. For $\mu \in \mathbb{C}^+$ with $|\mu| < \epsilon$ the operators $\mathcal{J}(\mu)A(\mu)^{-1}$ and $(\Delta_0 - \mu^2)^{-1}$ coincide as elements of $\mathcal{B}(L^2(\mathcal{M}), L^2_{r}(\mathcal{M}))$. Thus $\mathcal{J}(\mu)A(\mu)^{-1}$ provides the resolvent

$$\mathbb{C}^+ \ni \mu \mapsto (\Delta_0 - \mu^2)^{-1} \in \mathcal{B}(L^2(\mathcal{M}), L^2_{r}(\mathcal{M}))$$

with meromorphic continuation to the disc $|\mu| < \epsilon$.

**Proof.** 1. For $|\mu| < \epsilon$ the operator $A(\mu)$ is Fredholm as a finite-rank extension of a Fredholm operator, see Lemma [II]. It is easy to see that for any $(u, c) \in \mathcal{D}_\epsilon \times \mathbb{C}^n$ the function $\mu \mapsto A(\mu)(u, c)$ is holomorphic in the disc $|\mu| < \epsilon$. Assume, in addition, that $\mu \in \mathbb{C}^+$. Then for any $(u, c) \in \mathcal{D}_\epsilon \times \mathbb{C}^n$ we have $\mathcal{J}(\mu)(u, c) \in L^2(\mathcal{M})$ and $\mu^2$ is a regular point of the nonnegative selfadjoint operator $\Delta_0$. Hence $\dim \ker A(\mu) = 0$. Indeed, for any $(u, c) \in \ker A(\mu)$ we have $(\Delta_0 - \mu^2)\mathcal{J}(\mu)(u, c) = 0$, which implies $\mathcal{J}(\mu)(u, c) = 0$, and therefore $v = 0$ and $a = 0$. Besides, by Lemma [II] for any $f \in L^2(\mathcal{M})$ we have
(\Delta_0 - \mu^2)^{-1} f = u + \sum c_k \phi_k(\mu) \text{ with } u \in \mathcal{D}_\epsilon \text{ and } c \in \mathbb{C}^n. \text{ Therefore } A(\mu)(u, c) = f \text{ and the operator } A(\mu) \text{ is invertible. Assertion 1 is proved.}

2. It is easy to see that \( A(0) \bar{\mathcal{J}}(0)^{-1} = 0 \); here \( \bar{\mathcal{J}}(0)^{-1} = (1 - \sum \phi_k(0), 1, \ldots, 1) \). Moreover, since there are no other bounded solutions to \( \Delta u = 0 \) than a constant, this proves the first equality in Assertion 2. For \( v \) in the kernel of the adjoint operator \( A(0)^* : L^2_{*} \to \mathcal{D}^* \times \mathbb{C}^n \) and any \((u, c) \in \mathcal{D} \times \mathbb{C}^n\) we have

\[
(\Delta_\epsilon u, v)_{L^2_{\epsilon}(\mathcal{M})} + \sum c_k (\Delta \phi_k(0), v)_{L^2_{\epsilon}(\mathcal{M})} = 0.
\]

Therefore \( v \) is an element in \( \ker(\Delta_\epsilon)^* \subset \mathcal{D} \), satisfying \( (\Delta \phi_k(0), v)_{L^2_{\epsilon}(\mathcal{M})} = 0, 1 \leq k \leq n \); here \( (\Delta_\epsilon)^* \) is the adjoint to \( \Delta_\epsilon \) in-sectorial operator in \( L^2_{\epsilon}(\mathcal{M}) \) with domain \( \mathcal{D} \), see Proof of Lemma 1 in Appendix. Separation of variables in the cylindrical ends gives

\[
e_{2\epsilon}(x)v(x, y) = A_k x + \sum_{\ell \in \mathbb{Z}} B^\ell_k e^{2\pi |O_k|^{-1}(-|x| + i\ell y)},
\]

where \( A_k \) and \( B^\ell_k \) are some coefficients. Next we show that \( A_k = 0 \). Consider, for instance, a right cylindrical end (with cross-section \( O_k \)). Then by using the Green formula we get

\[
0 = (\Delta \phi_k(0), v)_{L^2_{\epsilon}(\mathcal{M})} = \lim_{T \to +\infty} \int_{O_k} \int_R e_{2\epsilon}(x) \Delta \phi_k(0; x, y) v(x, y) \, dx \, dy
\]

\[
= \lim_{T \to +\infty} \int_{O_k} \phi_k(0; T, y) \partial_x(e_{2\epsilon}v)(T, y) \, dy = |O_k| A_k
\]

and hence \( A_k = 0 \). Similarly one can see that \( A_k = 0 \) for the left cylindrical ends. This together with \( (2.8) \) implies that \( e_{2\epsilon}v \) is a bounded solution and thus it is a constant. Assertion 2 is proved.

3. Taking the derivative in \( (2.6) \) we obtain \( \partial_\mu A(0) \bar{\mathcal{J}}(0)^{-1} = \sum \Delta \partial_\mu \phi_k(0) \). The equation for \((v, d)\) takes the form

\[
A(0)(v, d) = -\sum \Delta \partial_\mu \phi_k(0).
\]

This equation has no solutions since its right hand side is not orthogonal to \( e_{-2\epsilon} \in \ker A(0)^* \). Indeed,

\[
(\Delta \partial_\mu \phi_k(0), e_{-2\epsilon})_{L^2_{\epsilon}(\mathcal{M})} = \lim_{T \to +\infty} \int_{O_k} \int_R \Delta \partial_\mu \phi_k(0; x, y) \, dx \, dy
\]

\[
= -\lim_{T \to +\infty} \int_{O_k} \partial_x \partial_\mu \phi_k(0; T, y) \, dy = -\lim_{T \to +\infty} \int_{O_k} i \, dy = -i|O_k|
\]

if \( O_k \) corresponds to a right cylindrical end; in the same way one can check that \( (\Delta \partial_\mu \phi_k(0), e_{-2\epsilon})_{L^2_{\epsilon}(\mathcal{M})} = -i|O_k| \) for the left cylindrical ends. Thus

\[
\sum (\Delta \partial_\mu \phi_k(0), e_{-2\epsilon})_{L^2_{\epsilon}(\mathcal{M})} = -2i
\]

and there are no generalized eigenvectors. Assertion 3 is proved.

4. Assertion 4 is the representation \( (2.7) \) written for \( A(\mu)^{-1} \) and \( \mu_0 = 0 \). Indeed, \( \psi_0 = \bar{\mathcal{J}}(0)^{-1}1 \) is an eigenvector of \( A(\mu) \) at \( \mu = 0 \), and \( \omega_0(\cdot) = \frac{i}{2} (\cdot, 1)_{L^2(\mathcal{M})} \) because

\[
\omega_0(\partial_\mu F(\mu_0) \psi_0) = \frac{i}{2} (\partial_\mu A(0) \bar{\mathcal{J}}(0)^{-1}1, 1)_{L^2(\mathcal{M})} = \frac{i}{2} \sum (\Delta \partial_\mu \phi_k(0), e_{-2\epsilon})_{L^2_{\epsilon}(\mathcal{M})} = 1
\]
as we need.

5. For \( \mu \in \mathbb{C}^+ \) with \(|\mu| < \epsilon \) and any \( f \in L^2(M) \) we have \((\Delta_0 - \mu^2)^{-1}f = \mathcal{J}(\mu)A(\mu)^{-1}f\), which means that the operators \((\Delta_0 - \mu^2)^{-1}\) and \(\mathcal{J}(\mu)A(\mu)^{-1}\) in \(\mathcal{B}(L^2(M), L^2_{\mathcal{C}}(M))\) are coincident. Clearly, \( \mu \mapsto \mathcal{J}(\mu) \) is holomorphic in the disc \(|\mu| < \epsilon \). Thus the meromorphic in the disc \(|\mu| < \epsilon \) function \( \mu \mapsto \mathcal{J}(\mu)A(\mu)^{-1} \in \mathcal{B}(L^2(M), L^2_{\mathcal{C}}(M)) \) provides the resolvent \((\Delta_0 - \mu^2)^{-1}\) with the desired continuation. Assertion 5 is proved. \( \square \)

**Proof of Theorem 2** As a consequence of Assertions 4 and 5 of Proposition 1 we have

\[
(\Delta_0 - \mu^2)^{-1} = \mathcal{J}(\mu)A(\mu)^{-1} = \frac{i}{2\mu}(\cdot, 1)_{L^2(M)} + \Phi(\mu),
\]

\[
\Phi(\mu) = \frac{i}{2\mu}(\cdot, 1)_{L^2(M)}(\mathcal{J}(\mu) - \mathcal{J}(0))\mathcal{J}(0)^{-1}1 + \mathcal{J}(\mu)\mathcal{H}(\mu),
\]

where \( \mu \mapsto \Phi(\mu) \in \mathcal{B}(L^2(M), L^2_{\mathcal{C}}(M)) \) is holomorphic in the disc \(|\mu| < \epsilon \). Theorem 2 is proved. \( \square \)

### 2.2 Dirichlet-to-Neumann operator

As before we assume that \( R > 0 \) is so large that there are no conical points on \( M \) with coordinate \( x \notin (-R, R) \) and denote \( \Gamma = \{ p \in M : |x| = R \} \). Then for \( \mu^2 \in \mathbb{C} \setminus (0, \infty) \) and any \( f \in C^\infty(\Gamma) \) there exists a unique bounded at infinity solution to the Dirichlet problem

\[
(\Delta - \mu^2)u(\mu) = 0 \text{ on } M \setminus \Gamma, \quad u(\mu) = f \text{ on } \Gamma,
\]

such that

\[
u(\mu) = \tilde{f} - (\Delta_{\text{in}}^D - \mu^2)^{-1}(\Delta - \mu^2)\tilde{f} \text{ on } M_{\text{in}},
\]

where \( \tilde{f} \in C^\infty(M_{\text{in}} \setminus \mathcal{P}) \) is an extension of \( f \) and \( \Delta_{\text{in}}^D \) is the Friedrichs selfadjoint extension of the Dirichlet Laplacian on \( M_{\text{in}} = \{ p \in M : |x| \leq R \} \). We introduce the Dirichlet-to-Neumann operator

\[
\mathcal{N}(\mu^2)f = \lim_{x \to R_+} \langle -\partial_x u(\mu; -x), \partial_x u(\mu; x) \rangle + \lim_{x \to R_-} \langle \partial_x u(\mu; -x), -\partial_x u(\mu; x) \rangle;
\]

here \( \langle \cdot, \cdot \rangle \in L^2(\Gamma_-) \oplus L^2(\Gamma_+) \equiv L^2(\Gamma) \) with \( \Gamma = \{ p \in M : |x| = \pm R \} \).

**Theorem 3.** Let \( \epsilon > 0 \) be sufficiently small. Then the functions

\[
\mu \mapsto \mathcal{N}(\mu^2) \in \mathcal{B}(H^1(\Gamma); L^2(\Gamma)), \quad \mu \mapsto \mathcal{N}(\mu^2)^{-1} - \frac{i}{2\mu}(\cdot, 1)_{L^2(\Gamma)} \in \mathcal{B}(L^2(\Gamma)),
\]

and \( \mu \mapsto \det \mathcal{N}(\mu^2) \in \mathbb{C} \) are holomorphic in the disc \(|\mu| < \epsilon \), where \( \det \mathcal{N}(\mu^2) \) is the zeta regularized determinant of \( \mathcal{N}(\mu^2) \). Moreover, as \( \mu \) tends to zero we have

\[
\det \mathcal{N}(\mu^2) = -i\mu(\det^* \mathcal{N}(0) + O(\mu)),
\]

where \( \mathcal{N}(0) \) has zero as an eigenvalue and \( \det^* \mathcal{N}(0) \in \mathbb{R} \) is the corresponding zeta regularized determinant with zero eigenvalue excluded.

**Proof.** The main idea of the proof is essentially the same as in [1, Theorem B*] and [24, Theorem B].

First we show that \( \mathcal{N}(\mu^2) \in \mathcal{B}(H^1(\Gamma); L^2(\Gamma)) \) is holomorphic in \( \mu, |\mu| < \epsilon \). Since \( \Delta_{\text{in}}^D \) is a positive selfadjoint operator, its resolvent \((\Delta_{\text{in}}^D - \mu^2)^{-1} : H^{-1/2}(M_{\text{in}}) \to H^{3/2}(M_{\text{in}}) \) is
a holomorphic function of $\mu^2$ in the sufficiently small disc $|\mu^2| < \varepsilon^2$; here $\|v; H^k(M_{in})\| = \|((\Delta_{in})^k)^{1/2}v; L^2(M_{in})\|$. Let $\tilde{f} \in H^{3/2}(M_{in})$ be a continuation of $f \in H^1(\Gamma)$. Then in the small disc $|\mu| < \varepsilon$ the equality \eqref{2.10} defines a holomorphic family of operators mapping $H^1(\Gamma) \ni f \mapsto u(\mu) \in H^{3/2}(M_{in})$. As a consequence, for any $f \in H^1(\Gamma)$ the second limit in \eqref{2.11} is a holomorphic function of $\mu$ (more precisely of $\mu^2$), $|\mu| < \varepsilon$, with values in $L^2(\Gamma)$. The first limit in \eqref{2.11} also defines a holomorphic function of $\mu$ in a vicinity of $\Gamma$. Since $\tilde{f}$ is holomorphic with respect to $\mu$ operator in $\mathcal{B}(H^1(\Gamma), L^2(\Gamma))$ as it is seen from the explicit formulae

$$
\partial_x u(\mu; \pm (R+), y) = \pm \left( i\mu \int_{O_k} f(y') \, dy' - \sum_{\ell \in \mathbb{Z} \setminus \{0\}} \sqrt{4\pi^2 \ell^2 |O_k|^{-2} - \mu^2} \int_{O_k} f(y')e^{2\pi i \ell |O_k|^{-1}(y-y')} \, dy' \right), \quad y \in O_k, \; 1 \leq k \leq n,
$$

obtained by separation of variables in the cylindrical ends; here $+$ signs (resp. $-$) are taken if $O_k$ corresponds to a right (resp. left) cylindrical end.

On the next step we make use of the representation

$$
N(\mu^2)^{-1} = ((\Delta_0 - \mu^2)^{-1}(\cdot \otimes \delta_\Gamma)) |_{\Gamma}, \quad \tag{2.13}
$$

where $\delta_\Gamma$ is the Dirac $\delta$-function along $\Gamma$, the action of the resolvent on $(\cdot \otimes \delta_\Gamma)$ is understood in the sense of distributions, and $\mid_{\Gamma}$ is the restriction map to $\Gamma$; for a proof of \eqref{2.13} see [2, Proof of Theorem 2.1].

Let $\varrho$ be a smooth cutoff function on $M$ supported in a small neighborhood of $\Gamma$ and such that $\varrho = 1$ in a vicinity of $\Gamma$. Since $\varrho$ is supported outside of conical points, the local elliptic coercive estimate

$$
\|\varrho u; H^1(M)\| \leq C(\|\varrho \Delta u; H^{-1}(M)\| + \|\varrho u; L^2(M)\| \tag{2.14}
$$
is valid, where $\varrho \in C_0^\infty(M \setminus D)$ and $\varrho \varrho = \varrho$. In particular, for

$$
u = \Phi(\mu) f := (\Delta_0 - \mu^2)^{-1} f - \frac{i}{2\mu} (f, 1)_{L^2(M)} \tag{2.11}
$$

implies

$$
\|\varrho \Phi(\mu) f; H^1(M)\| \leq C(\|f; L^2(M)\| + |\mu|^2 \|(\Delta_0 - \mu^2)^{-1} f; L^2_\varepsilon(M)\| + \|\Phi(\mu) f; L^2_\varepsilon(M)\|).
$$

This together with Theorem 2 shows that $\mu \mapsto \varrho \Phi(\mu) \in \mathcal{B}(L^2_\varepsilon(M); H^1(M))$ is holomorphic in the disc $|\mu| < \varepsilon$. Since the mapping $L^2(\Gamma) \ni \psi \mapsto \psi \otimes \delta_\Gamma \in H^{-1}(M) = (H^1(M))^*$ is continuous, for any $f \in L^2_\varepsilon(M)$ we have

$$
((\Delta_0 - \mu^2)^{-1}(\cdot \otimes \delta_\Gamma) f)_{L^2(M)} = \left( \cdot \otimes \delta_\Gamma, \varrho \Phi(\mu) f \right)_{L^2(M)} = \frac{i}{2\mu} \left( \cdot, 1 \right)_{L^2(\Gamma)} (1, f)_{L^2(M)} + \left( \cdot \otimes \delta_\Gamma, \Phi(\mu) f \right)_{L^2(M)},
$$

where $(\cdot, \cdot)_{L^2(M)}$ is extended to the pairs in $H^{-1}(M) \times H^1(M)$ and $L^2_\varepsilon(M) \times L^2_\varepsilon(M)$. In other words, the equality

$$
(\Delta_0 - \mu^2)^{-1}(\cdot \otimes \delta_\Gamma) = \frac{i}{2\mu} (\cdot, 1)_{L^2(\Gamma)} + \Phi(\mu), \; |\mu| < \varepsilon, \tag{2.15}
$$
holds in $L^2_{-\epsilon}(\mathcal{M})$, where $\mu \mapsto \mathcal{H}(\mu) \in \mathcal{B}(L^2(\Gamma), L^2_{-\epsilon}(\mathcal{M}))$ is holomorphic. We substitute $u = \mathcal{H}(\mu) \psi$ into \eqref{2.14} and obtain
\[
\|\mathcal{H}(\mu) \psi; H^1(\mathcal{M})\| \leq C(||\psi \otimes \delta_\Gamma; H^{-1}(\mathcal{M})||
+ |\mu|^2(|\Delta_0 - \mu^2|^{-1}(\psi \otimes \delta_\Gamma); L^2_{-\epsilon}(\mathcal{M})|| + ||\mathcal{H}(\mu) \psi; L^2_{-\epsilon}(\mathcal{M})||).
\]
Thus $\mu \mapsto \mathcal{H}(\mu) \in \mathcal{B}(L^2(\Gamma); H^1(\mathcal{M}))$ is holomorphic. Now from \eqref{2.15}, \eqref{2.13}, and continuity of the embedding $H^1(\mathcal{M})|_\Gamma \hookrightarrow L^2(\Gamma)$ we conclude that
\[
\mathcal{N}(\mu^2)^{-1} = \frac{i}{2\mu} (\cdot, 1)_{L^2(\Gamma)} + \mathcal{H}_\Gamma(\mu), \quad |\mu| < \epsilon,
\]
where $\mathcal{H}_\Gamma(\mu) \psi = (\mathcal{H}(\mu) \psi)|_\Gamma$ and $\mu \mapsto \mathcal{H}_\Gamma(\mu) \in \mathcal{B}(L^2(\Gamma))$ is holomorphic. In particular, \eqref{2.16} implies that zero is a simple eigenvalue of $\mathcal{N}(0)$ and ker $\mathcal{N}(0) = \{ c \in \mathbb{C} \}$; cf. \eqref{2.7}.

The operator $\mathcal{N}(\mu^2)$ is an elliptic classical pseudodifferential operator on $\Gamma$ (all conical points of $\mathcal{M}$ are outside of $\Gamma$ and thus do not affect properties of the symbol of $\mathcal{N}(\mu^2)$), e.g. from \eqref{2.13} one can see that the principal symbol of $\mathcal{N}(\mu^2)$ is $2\xi$. Besides, \eqref{2.13} implies that $\mathcal{N}(\mu^2)$ with $\mu^2 \leq 0$ is formally selfadjoint, and $\mathcal{N}(\mu^2)$ is positive if $\mu^2 < 0$ and nonnegative if $\mu = 0$. Therefore the closed unbounded operator $\mathcal{N}(\mu^2)$ in $L^2(\Gamma)$ with domain $H^1(\Gamma)$ is selfadjoint for $\mu^2 \leq 0$, it is positive if $\mu^2 < 0$, and nonnegative if $\mu = 0$, e.g. \cite{13}.

Let $\mu \in i[0, \epsilon)$ and let $0 \leq \lambda_1(\mu) \leq \lambda_2(\mu) \leq \lambda_3(\mu) \leq \cdots$ be the eigenvalues of the selfadjoint operator $\mathcal{N}(\mu^2)$. The operator $\mathcal{N}(\mu^2)$, and therefore its eigenvalues and eigenfunctions, are holomorphic functions of $\mu$ in the disc $|\mu| < \epsilon$; e.g. \cite{13} Chapter VII). Since $\epsilon$ is sufficiently small, the eigenvalue $\lambda_1(\mu)$ remains simple for $|\mu| < \epsilon$ and $\lambda_1(\mu) \to 0$ as $\mu \to 0$, while all other eigenvalues satisfy $\delta < |\lambda_2(\mu)| \leq |\lambda_3(\mu)| \leq \cdots$ with some $\delta > 0$. Let $\psi(\mu)$ be the eigenfunction corresponding to the eigenvalue $\lambda_1(\mu)$ of $\mathcal{N}(\mu^2)$ and satisfying $(\psi(\mu), \psi(-\bar{\mu}))_{L^2(\Gamma)} = 1$; clearly, $\psi(0) = 2^{-1/2}$. The equality
\[
1/\lambda_1(\mu) = (\mathcal{N}(\mu^2)^{-1} \psi(\mu), \psi(-\bar{\mu}))_{L^2(\Gamma)}, \quad \mu \in i(0, \epsilon)
\]
extends by analyticity to the punctured disc $|\mu| < \epsilon, \mu \neq 0$. This together with \eqref{2.16} and $\|\psi(\mu) - 2^{-1/2}; L^2(\Gamma)\| = O(|\mu|)$ gives
\[
\lambda_1(\mu) = -i\mu + O(\mu^2), \quad |\mu| < \epsilon.
\]
For $\mu \neq 0$ the operator $\mathcal{N}(\mu^2)$ is invertible, the function $\zeta(s) = \text{Tr} \mathcal{N}(\mu^2)^{-s}$ is holomorphic in $\{s \in \mathbb{C}: Re s > 1\}$ and admits a meromorphic continuation to $\mathbb{C}$ with no pole at $s = 0$. We set $\det \mathcal{N}(\mu^2) = e^{-\partial_s \zeta(0)}$. Besides, the function $\zeta^*(s) = \text{Tr} \mathcal{N}_s(\mu^2)^{-s}$ of the invertible operator
\[
\mathcal{N}_s(\mu^2) = \mathcal{N}(\mu^2) + (1 - \lambda_1(\mu))(\cdot, \psi(-\bar{\mu}))_{L^2(\Gamma)} \psi(\mu), \quad |\mu| < \epsilon,
\]
is holomorphic in $\{s \in \mathbb{C}: Re s > 1\}$ and has a meromorphic continuation to $\mathbb{C}$ with no pole at $s = 0$; here the Riesz projection $(\cdot, \psi(-\bar{\mu}))_{L^2(\Gamma)} \psi(\mu)$ is a smoothing operator. We set $\det^* \mathcal{N}(\mu^2) = \det \mathcal{N}_s(\mu^2) = e^{-\partial_s \zeta^*(0)}$. Clearly,
\[
det \mathcal{N}(\mu^2) = \lambda_1(\mu) \det^* \mathcal{N}(\mu^2).
\]
Note that \((2.13)\) also implies that the order of pseudodifferential operator \(\partial_{\mu}^{\ell} N(\mu^{2})^{-1}\) is \(-1 - 2\ell\). Thus the order of \(\partial_{\mu}^{\ell} N(\mu^{2})\) is \(1 - 2\ell\), for \(\ell \geq 1\) and \(|\mu| < \epsilon\) the operator \(\partial_{\mu}^{\ell-1} \left[ (\partial_{\mu} N_{\epsilon}(\mu^{2})) N_{\epsilon}(\mu^{2})^{-1} \right]\) is trace class and

\[
\partial_{\mu} \log \det^{*} N(\mu^{2}) = \text{Tr} \left( \partial_{\mu}^{\ell-1} \left[ (\partial_{\mu} N_{\epsilon}(\mu^{2})) N_{\epsilon}(\mu^{2})^{-1} \right] \right),
\]

\[
\partial_{\mu} \log \det^{*} N(\mu^{2}) = \text{Tr} \left( (\partial_{\mu} N_{\epsilon}(\mu^{2})) N_{\epsilon}(\mu^{2})^{-1} \right) = 0;
\]

see [10] [1]. As a consequence, \(\mu \to \det^{*} N(\mu^{2})\) is holomorphic in the disc \(|\mu| < \epsilon\). This together with \((2.18)\) and \((2.17)\) completes the proof.

\(\square\)

2.3 Relative zeta function

Both perturbed and unperturbed Mandelstam diagrams can be considered as strips \(\Pi\) and \(\hat{\Pi}\) with different slits. Therefore \(L^{2}(\Pi) = L^{2}(\hat{\Pi})\) and the spaces \(L^{2}(M)\) and \(L^{2}(\hat{M})\) can be naturally identified. Starting from now on we consider only selfadjoint Friedrichs extensions \(\Delta\) and \(\hat{\Delta}\) in \(L^{2}(M)\); in other words, we set \(\epsilon = 0\) and omit it from notations.

**Lemma 3.** For all \(t > 0\) the operator \(e^{-t\Delta} - e^{-t\hat{\Delta}}\) is trace class and

\[
\text{Tr} \left( e^{-t\Delta} - e^{-t\hat{\Delta}} \right) = O(t^{-1/2}) \quad \text{as} \quad t \to +\infty.
\]

**Proof.** As is known [2] Theorem 2.2], \((\Delta + 1)^{-1} - (\Delta_{D}^{in} \oplus \Delta_{D}^{out} + 1)^{-1}\) is trace class; here \(\Delta_{D}^{in}\) is the same as in the section 2.2 and \(\Delta_{D}^{out}\) is the selfadjoint Friedrichs extension of the Dirichlet Laplacian on \(M_{out} = \{ p \in M; |x| \geq R \}\), i.e. \(\Delta_{D}^{in} \oplus \Delta_{D}^{out}\) is the operator of the Dirichlet problem \((2.9)\). Then by the Krein theorem, see e.g. [36, Chapter 8.9] or [2, Theorem 3.3], there exists a spectral shift function \(\xi \in L^{1}(\mathbb{R}_{+}, (1 + \lambda)^{-2} d\lambda)\) such that

\[
\text{Tr} \left( (\Delta + 1)^{-1} - (\Delta_{D}^{in} \oplus \Delta_{D}^{out} + 1)^{-1} \right) = - \int_{0}^{\infty} \xi(\lambda) (1 + \lambda)^{-2} d\lambda.
\]

Moreover, the following representation is valid

\[
\text{Tr} \left( e^{-t\Delta} - e^{-t\Delta_{D}^{in} \oplus \Delta_{D}^{out}} \right) = -t \int_{0}^{\infty} e^{-t\lambda} \xi(\lambda) d\lambda,
\]

where the right hand side is finite. Thus \(e^{-t\Delta} - e^{-t\Delta_{D}^{in} \oplus \Delta_{D}^{out}}\) is trace class. Besides, by [2, Theorem 3.5] we have

\[
\xi(\lambda) = \pi^{-1} \arg \det N(\lambda + i0), \quad \lambda > 0.
\]

This together with \((2.12)\) gives \(\xi(\lambda) = 3/2 + O(\sqrt{\lambda})\) as \(\lambda \to 0^{+}\). As a consequence, the right hand side of \((2.20)\) provides the left hand side with asymptotic

\[
\text{Tr} \left( e^{-t\Delta} - e^{-t\Delta_{D}^{in} \oplus \Delta_{D}^{out}} \right) = 3/2 + O(t^{-1/2}) \quad \text{as} \quad t \to +\infty.
\]

Similarly we conclude that \(e^{-t\Delta} - e^{-t\hat{\Delta}_{D}^{in} \oplus \hat{\Delta}_{D}^{out}}\) is trace class and

\[
\text{Tr} \left( e^{-t\Delta} - e^{-t\hat{\Delta}_{D}^{in} \oplus \hat{\Delta}_{D}^{out}} \right) = 3/2 + O(t^{-1/2}) \quad \text{as} \quad t \to +\infty;
\]

here the operators \(\hat{\Delta}_{D}^{in}\) and \(\hat{\Delta}_{D}^{out}\) of the Dirichlet problems on \(\{ p \in M : |x| \leq R \}\) and \(\{ p \in M : |x| \geq R \}\) respectively are introduced in the same way as \(\Delta_{D}^{in}\) and \(\Delta_{D}^{out}\). For the operator \(\Delta_{D}^{in}\) (resp. \(\hat{\Delta}_{D}^{in}\)) on compact manifold it is known that \(e^{-t\Delta_{D}^{in}}\) (resp. \(e^{-t\hat{\Delta}_{D}^{in}}\)) is trace class and \(\text{Tr} e^{-t\Delta_{D}^{in}} = O(e^{-\lambda t})\) (resp. \(\text{Tr} e^{-t\hat{\Delta}_{D}^{in}} = O(e^{-\lambda t})\)) as \(t \to +\infty\), where \(\lambda > 0\) is the first eigenvalue of \(\Delta_{D}^{in}\) (resp. \(\hat{\Delta}_{D}^{in}\)). Since \(\Delta_{D}^{out} \equiv \hat{\Delta}_{D}^{out}\), this together with \((2.22)\) and \((2.23)\) completes the proof.

\(\square\)
Remark 1. In the general framework [29] (see also [31, 30]) the long time behavior of \( \text{Tr}(e^{-t\Delta} - e^{-t\Delta^{D}_n \oplus \Delta^{D}_0}) \) is supposed to be studied via properties of the corresponding scattering matrix near the bottom of the continuous spectrum (as it naturally follows from [2.20] and the Birman-Krein theorem). In contrast to this, in the proof of Lemma 3 we follow the original idea of Carron [2, Theorem 3.5], [3] and immediately obtain the result relying on (2.21) and (2.12).

Lemma 4. Let \( K \) be the number of the interior slits of the diagram \( \mathcal{M} \). Then for some \( \delta > 0 \)

\[
\text{Tr}(e^{-t\Delta} - e^{-t\hat{\Delta}}) = -K/4 + O(e^{-\delta/t})
\]  

(2.24)
as \( t \to 0^+ \).

Proof. Let \{\( \mathcal{U}_j \)\} be a finite covering of the flat surface \( M \) by open discs centered at conical points, flat open discs, and open semi-infinite cylinders and let \{\( \zeta_j \)\} be the \( C^\infty \) partition of unity subject to this covering. Let also \( \tilde{\zeta}_j \) be smooth functions supported in small neighborhoods of \( \mathcal{U}_j \) such that \( \zeta_j \tilde{\zeta}_j = \zeta_j \) and

\[
\text{dist}(\text{supp}\nabla \tilde{\zeta}_j, \text{supp}\zeta_j) > 0
\]

for all \( j \). Define a parametrix for the heat equation on \( \mathcal{M} \) as

\[
\mathcal{P}(p, q; t) = \sum_j \tilde{\zeta}_j(p)\mathcal{K}_j(p, q; t)\zeta_j(q),
\]

(2.25)

where \( \mathcal{K}_j \) is (depending on the type of the element \( \mathcal{U}_j \) of the covering) either the heat kernel on the infinite flat cone with conical angle \( 4\pi \) (see, e. g., [22], f-la (4.4)) or the standard heat kernel in \( \mathbb{R}^2 \) or the heat kernel

\[
H(x, y, x', y', t) = \frac{e^{-(x-x')^2/(4t)}}{\sqrt{4\pi t}} \sum_{n \in \mathbb{Z}} e^{i2\pi a^{-1}n(y-y')-4\pi^2n^2a^{-2}t}
\]

(2.26)
in the infinite cylinder with circumference \( a \) (the latter is the same as the circumference of the corresponding semi-infinite cylinder from the covering). One has the relation

\[
\lim_{t \to 0} \int_{\mathcal{M}} \mathcal{P}(x, y, x', y'; t) f(x', y') \, dx' \, dy' = f(x, y), \quad \forall f \in C^\infty_0(\mathcal{M})
\]

and the estimate

\[
|\mathcal{P}_1(x, y, x', y'; t)| \leq C e^{-\delta(1+x^2+y^2)/t}
\]

(2.27)

for \( \mathcal{P}_1(p, q; t) := (\partial_t - \Delta)\mathcal{P}(p, q; t) \) and some \( \delta > 0 \). To prove (2.27) one has to notice that \( \mathcal{P}_1(p, q; t) \) vanishes when \( p \) does not belong to the union of \( \text{supp}\nabla \tilde{\zeta}_j \) (which is a compact subset of \( \mathcal{M} \)) or when the distance between \( p \) and \( q \) is sufficiently small and then make use of the explicit expressions for the standard heat kernels in (2.25). Due to (2.27) one can construct the heat kernel on \( \mathcal{M} \) in the same way as it is usually done for compact manifolds (see, e. g. [28]). We introduce consecutively

\[
\mathcal{P}_{\ell+1}(x, y, x', y'; t) = \int_0^t \int_{\mathcal{M}} \mathcal{P}_1(x, y, \hat{x}, \hat{y}; t - \hat{\ell})\mathcal{P}_\ell(\hat{x}, \hat{y}, x', y'; t) \, d\hat{x} \, d\hat{y} \, d\hat{\ell}, \quad \ell \geq 1.
\]

(2.28)

By (2.27) the second integral in (2.28) is absolutely convergent and

\[
|\mathcal{P}_{\ell+1}(x, y, x', y'; t)| \leq e^{-\delta(1+x^2+y^2)/t}(ct)^\ell
\]

(2.29)
for some \( c > 0 \). For small \( t \) the heat kernel \( \mathcal{H} \) on \( M \) is given by

\[
\mathcal{H} = \mathcal{P} + \sum_{t=1}^{\infty} (-1)^t \mathcal{P}_t.
\]  

(2.30)

Moreover, one has the following estimate for the difference between the heat kernel and the parametrix \( \mathcal{P} \)

\[
|\mathcal{H}(x, y, x', y'; t) - \mathcal{P}(x, y, x', y'; t)| \leq C e^{-\delta(1+x^2+y^2)/t},
\]  

(2.31)

where \( t > 0 \) is sufficiently small, \( \delta \) and \( C \) are some positive constants.

Similarly one can construct a parametrix \( \mathcal{Q} \) and the heat kernel \( \mathcal{H} \) for the "free" diagram \( \tilde{M} \) (coinciding with \( M \) for \( |x| > R \), with sufficiently large \( R \)). Obviously, \( \mathcal{P}(p, p; t) = \mathcal{Q}(p, p; t) \) for \( p = (x, y), |x| > R \). Thus,

\[
\text{Tr}(e^{-t\Delta} - e^{-t\tilde{\Delta}}) = \int_M \mathcal{H}(x, y, x, y; t) dx dy - \int_M \hat{\mathcal{H}}(x, y, x, y; t) dx dy + O(e^{-\delta/t}),
\]

where \( \delta > 0 \) and \( t \downarrow 0 \). From (22), Theorem 8 it follows that the first integral at the right has the asymptotics

\[
\frac{\text{Area}(M \cap \{|x| < R\})}{4\pi t} + \frac{1}{12} \sum_k \left( \frac{2\pi}{\beta_k} - \frac{\beta_k}{2\pi} \right) + O(e^{-\delta/t}),
\]

as \( t \to 0^+ \), where the summation is over the conical points of \( M \) inside \( \{|x| < R\} \) and all the conical angles \( \beta_k \) are equal to \( 4\pi \). The second term has the similar asymptotics with \( \text{Area}(\tilde{M} \cap \{|x| < R\}) = \text{Area}(M \cap \{|x| < R\}) \) and smaller number of conical points (by \( 2K \), where \( K \) is the number of interior slits of the perturbed diagram \( M \)). This implies (22).

Now we are in position to introduce the relative zeta determinant \( \det(\Delta - \mu^2, \tilde{\Delta} - \mu^2) \) following [29]. As a consequence of Lemma 3 the function

\[
\zeta_{\infty}(s; \Delta - \mu^2, \tilde{\Delta} - \mu^2) = \frac{1}{\Gamma(s)} \int_1^\infty t^{s-1} e^{t\mu^2} \text{Tr}(e^{-t\Delta} - e^{-t\tilde{\Delta}}) dt, \quad \mu^2 \leq 0,
\]

is holomorphic in \( \{s \in \mathbb{C} : \Re s < 1/2\} \) (and \( \zeta_{\infty}(0; \Delta, \tilde{\Delta}) = 0 \)). Lemma 3 implies that the holomorphic in \( \{s \in \mathbb{C} : \Re s > 1\} \) function

\[
\zeta_0(s; \Delta - \mu^2, \tilde{\Delta} - \mu^2) = \frac{1}{\Gamma(s)} \int_0^1 t^{s-1} e^{t\mu^2} \text{Tr}(e^{-t\Delta} - e^{-t\tilde{\Delta}}) dt, \quad \mu^2 \leq 0,
\]

has a meromorphic extension to \( s \in \mathbb{C} \) with no pole at \( s = 0 \) (and \( \zeta_0(0; \Delta, \tilde{\Delta}) = -K/4 \)). We introduce the relative zeta function

\[
\zeta(s; \Delta - \mu^2, \tilde{\Delta} - \mu^2) = \zeta_0(s; \Delta - \mu^2, \tilde{\Delta} - \mu^2) + \zeta_{\infty}(s; \Delta - \mu^2, \tilde{\Delta} - \mu^2)
\]

and the corresponding relative determinant

\[
\det(\Delta - \mu^2, \tilde{\Delta} - \mu^2) = e^{-\partial_s \zeta(0; \Delta - \mu^2, \tilde{\Delta} - \mu^2)}, \quad \mu^2 \leq 0.
\]
Theorem 4.

$$\det(\Delta - \mu^2, \hat{\Delta} - \mu^2) = \det(\Delta, \hat{\Delta}) + o(1) \text{ as } \mu^2 \to 0.$$  \hfill (2.32)

Proof. From analytic continuations of $\zeta_0$ and $\zeta_\infty$ it is easily seen that as $\mu^2 \to 0$– we have

$$\partial_s \zeta_0(0; \Delta - \mu^2, \hat{\Delta} - \mu^2) = \partial_s \zeta_0(0; \Delta, \hat{\Delta}) + o(1),$$

$$\partial_s \zeta_\infty(0; \Delta - \mu^2, \hat{\Delta} - \mu^2) = \partial_s \zeta_\infty(0; \Delta, \hat{\Delta}) + o(1),$$

which proves the assertion. \hfill \Box

2.4 Decomposition formula

Proof of Theorem 1. The asymptotic

$$\text{Tr}(\text{e}^{-t\Delta} - \text{e}^{-t\Delta^D_{in} \oplus \Delta^D_{out}}) \sim \sum_{j \geq -2} a_j t^{j/2} \text{ as } t \to 0^+$$

(which can be established in the same way as (2.24)) together with (2.22) implies that the relative zeta function

$$\zeta(s; \Delta - \mu^2, \Delta^D_{in} \oplus \Delta^D_{out} - \mu^2) = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} e^{t\mu^2} \text{Tr}(\text{e}^{-t\Delta} - \text{e}^{-t\Delta^D_{in} \oplus \Delta^D_{out}}) \, dt, \quad \mu^2 < 0,$$

is holomorphic for $\{s \in \mathbb{C}; \Re s > 1\}$ and has a meromorphic extension to $s \in \mathbb{C}$ with no pole at $s = 0$. We set

$$\det(\Delta - \mu^2, \Delta^D_{in} \oplus \Delta^D_{out} - \mu^2) = e^{-\partial_s \zeta(0; \Delta - \mu^2, \Delta^D_{in} \oplus \Delta^D_{out} - \mu^2)}.$$

Similarly we define $\det(\hat{\Delta} - \mu^2, \hat{\Delta}^D_{in} \oplus \Delta^D_{out} - \mu^2)$. Then by [2, Theorem 4.2] we have

$$\det(\Delta - \mu^2, \Delta^D_{in} \oplus \Delta^D_{out} - \mu^2) = \det N(\mu^2); \quad \det(\hat{\Delta} - \mu^2, \hat{\Delta}^D_{in} \oplus \Delta^D_{out} - \mu^2) = \det \hat{N}(\mu^2).$$

Dividing the first equality by the second one we get

$$\frac{\det(\Delta - \mu^2, \hat{\Delta} - \mu^2) \det(\hat{\Delta}^D_{in} - \mu^2)}{\det(\Delta^D_{in} - \mu^2)} = \frac{\det N(\mu^2)}{\det \hat{N}(\mu^2)},$$

(2.33)

where $\det(\Delta^D_{in} - \mu^2)$ and $\det(\hat{\Delta}^D_{in} - \mu^2)$ are the zeta regularized determinants of Dirichlet Laplacians on compact manifolds. Since $\Delta^D_{in}$ is positive, we have $\det(\Delta^D_{in} - \mu^2) \to \det \Delta^D_{in}$ as $\mu^2 \to 0$, and the same is true for $\hat{\Delta}^D_{in}$. Thanks to (2.32) and Theorem 3 applied to $N(\mu^2)$ and $\hat{N}(\mu^2)$ we can pass in (2.33) to the limit as $\mu^2 \to 0$– and obtain

$$\frac{\det(\Delta, \hat{\Delta}) \det \hat{\Delta}^D_{in}}{\det \Delta^D_{in}} = \frac{\det^* N(0)}{\det^* \hat{N}(0)}.$$

Since $\det \hat{\Delta}^D_{in}$ and $\det^* \hat{N}(0)$ are moduli independent, this proves Theorem 1 where $C = (\det \hat{\Delta}^D_{in} \det^* \hat{N}(0))^{-1}$ and $N = N(0)$. \hfill \Box
3 Variational formulas for the relative determinant

3.1 Compactification of the ends

In the holomorphic local parameter \( \zeta_k = \exp(\pm 2\pi z/|O_k|), \) \( z = x + iy \) in a vicinity \( U_k = \{ x > R \} \) (or \( \{ x < -R \} \)) of the point at infinity \( \zeta_k = 0 \) of the \( k \)-th cylindrical end of \( M \) the flat metric \( m \) on \( M \) is written in the form

\[
m = \frac{|O_k|^2 |d\zeta_k|^2}{4\pi^2 |\zeta_k|^2}.
\]

Let \( \chi_k \) be a smooth function on \( \mathbb{C} \) such that \( \chi_k(\zeta) = \chi_k(|\zeta|), \) \( |\chi_k(\zeta)| \leq 1, \) \( \chi_k(\zeta) = 0 \) if \( |\zeta| > \exp(-2\pi(R+1)/|O_k|) \) and \( \chi(\zeta) = 1 \) if \( |\zeta| < \exp(-2\pi(R+2)/|O_k|) \). Introduce another metric \( \tilde{m} \) on \( M \) by

\[
\tilde{m} = \begin{cases} 
m & \text{for } |x| < R; \\
[1 + (|\zeta_k|^2 - 1)\chi(\zeta_k)]m & \text{in } U_k.
\end{cases}
\]

Applying BFK decomposition formula [1, Theorem B*] to the determinant of the Laplacian \( \Delta_{\tilde{m}} \) on the compact Riemannian manifold \((\tilde{M}, \tilde{m})\), we get

\[
\log \det \Delta_{\tilde{m}} = \log C_0 + \log \det \Delta^D_{\tilde{m}} + \log \det^* N + \log \det \Delta_{\text{ext}}, \tag{3.1}
\]

where \( \Delta_{\text{ext}} \) is the operator of the Dirichlet problem for \( \Delta_{\tilde{m}} \) in \( M \setminus \{ |x| < R \} \),

\[
C_0 = \frac{\text{Area}(\tilde{M}, \tilde{m})}{\sum |O_k|},
\]

and \( N \) is the same as in (2.1). From (2.1) and (3.1) it follows that \( \log \det \Delta_{\tilde{m}} \) and \( \log \det(\Delta, \tilde{\Delta}) \) have the same variations with respect to moduli \( h_k, \theta_k, \tau_k \) and, therefore,

\[
\det \Delta_{\tilde{m}} = C \det(\Delta, \tilde{\Delta})
\]

with moduli independent factor \( C \).

3.2 Variational formulas for resolvent kernel

Denote by \( G(\cdot, \cdot; \lambda) \) the resolvent kernel of the Laplace operator \( \Delta_{\tilde{m}} \). From now on we assume that the spectral parameter \( \lambda \) is real, so \( G(\cdot, \cdot; \lambda) \) is a real-valued function.

Introduce the one-form \( \omega \) on \( M \)

\[
\omega = G(P, z, \bar{z}; \lambda)G_{z\bar{z}}(Q, z, \bar{z}; \lambda)d\bar{z} + G_z(P, z, \bar{z}; \lambda)G_{z\bar{z}}(Q, z, \bar{z}; \lambda)dz.
\tag{3.2}
\]

Clearly, \( d\omega = 0 \) on \( M \cap \{ |x| < R \} \).

The following proposition describes the variations of the resolvent kernel \( G(P, Q; \lambda) \) under variations of moduli parameters. It is assumed that positions of the points \( P \) and \( Q \) on the diagram are kept fixed when the moduli vary.

Proposition 2.

\[
\frac{\partial G(P, Q; \lambda)}{\partial \theta_k} = 4\Re \left\{ \int_{\gamma_k} \omega \right\}, \quad k = 1, \ldots, 3g + n - 3; \tag{3.3}
\]
Here $\gamma_k$ are the contours along which the twists $\theta_k$ are performed, $b_k$ are $b$-cycles on the Riemann surface $M$ encircling the finite cuts of the diagram, contours $A_k, A'_k$ and $C_k$ coincide with circumferences of the three cylinders joining at the moment of "time" $x = \tau_k$, the choice of sign $\pm$ depends on the position of the cylinders (two at the left and one at the right or vice versa), see Fig. 3.

In the proof of Proposition 2 we will make use of the representation of a solution to the homogeneous Helmholtz equation given by the following Lemma.

**Lemma 5.** Let $G(z, \bar{z}, \xi, \bar{\xi}; \lambda)$ be the resolvent kernel of the operator $\Delta^{\bar{m}}$, and let $u$ be a solution to

$$\Delta^{\bar{m}} u - \lambda u = 0$$

in $M$. Let also $\Omega \subset M$ be an open subset of $M$ with piece-wise smooth boundary. Then for any $P \in \Omega, P = (\xi, \bar{\xi})$ one has the relation

$$u(\xi, \bar{\xi}) = -2i \int_{\partial\Omega} G(z, \bar{z}, \xi, \bar{\xi}; \lambda) u_{\bar{z}}(z, \bar{z}) d\bar{z} + G_z(z, \bar{z}, \xi, \bar{\xi}; \lambda) u(z, \bar{z}) dz.$$  

(3.7)

**Proof of Lemma 5** Applying Stokes theorem to the integral over the boundary of the domain $\Omega_\epsilon = \Omega \setminus \{ |z - \xi| \leq \epsilon \}$, one gets the relation

$$\int_{\partial\Omega_\epsilon} G(z, \bar{z}, \xi, \bar{\xi}; \lambda) u_{\bar{z}}(z, \bar{z}) d\bar{z} + G_z(z, \bar{z}, \xi, \bar{\xi}; \lambda) u(z, \bar{z}) dz = \int\int_{\Omega_\epsilon} (G_{u_{\bar{z}}} - G_{\bar{z}z} u) dz \wedge d\bar{z}$$

$$= \int\int_{\Omega_\epsilon} \frac{1}{\rho(z, \bar{z})} \{ G(\Delta^{\bar{m}} u - \lambda u) - (\Delta^{\bar{m}} G - \lambda G) u \} dz \wedge d\bar{z} = 0,$$

(3.7)
where $\Delta^m = \rho(z, \bar{z}) \partial_z \partial_{\bar{z}}$ in the conformal local parameter $z$. Sending $\epsilon$ to 0 and using the asymptotics

$$G(z, \bar{z}, \xi, \bar{\xi}; \lambda) = \frac{1}{2\pi} \log |z - \xi| + O(1)$$

as $z \to \xi$, one gets (3.7).

**Proof of Proposition [2]** Let us prove (3.3).

Let $\Omega$ be the surface $M$ cut along the twist contour $\gamma_k$. Denote the differentiation with respect to $\theta_k$ by dot. The function $\dot{G}(P, \cdot; \lambda)$ satisfies homogeneous Helmholtz equation (3.8). (Note that the singularity of $G(P, \cdot; \lambda)$ at $P$ disappears after differentiation with respect to $\theta_k$.) Differentiating the relation

$$G_-(P,z,\bar{z};\{\ldots,\theta_k,\ldots\}) = G_+(P,z + i\theta_k,\bar{z} + i\bar{\theta}_k,\lambda;\{\ldots,\theta_k,\ldots\})$$

for the left and right limit values of $G(P, \cdot; \lambda)$ at the contour $\gamma_k$ (we remind the reader that $G$ implicitly depends on moduli, this dependence is indicated in the previous formula), we get

$$\dot{G}_-(P,z,\bar{z};\lambda) = \dot{G}_+(P,z,\bar{z};\lambda) + i(G_z(P,z,\bar{z};\lambda) - \dot{G}_z(P,z,\bar{z},\lambda)), \tag{3.8}$$

$$\dot{(G_z)}_-(P,z,\bar{z};\lambda) = \dot{(G_z)}_+(P,z,\bar{z};\lambda) + i(G_{z\bar{z}}(P,z,\bar{z};\lambda) - \dot{G}_{z\bar{z}}(P,z,\bar{z},\lambda)). \tag{3.9}$$

Assuming that the contour $\gamma_k$ is not homologous to zero and using (3.7), (3.8) and (3.9), we get

$$\dot{G}(P,Q;\lambda) = 2\int_{\gamma_k} G(z,\bar{z},Q;\lambda) [G_{z\bar{z}}(P,z,\bar{z};\lambda) - \dot{G}_{z\bar{z}}(P,z,\bar{z},\lambda)] d\bar{z}$$

$$+ G_z(z,\bar{z},Q;\lambda) [G_z(P,z,\bar{z};\lambda) - G_{z\bar{z}}(P,z,\bar{z},\lambda)] dz$$

$$= 2\int_{\gamma_k} \omega(P,Q) + \overline{\omega(P,Q)} - d (G(Q,z,\bar{z};\lambda)G_z(P,z,\bar{z},\lambda)) = 4\Re \left\{ \int_{\gamma_k} \omega \right\}.$$ 

In the case of homologically trivial contour $\gamma_k$ dividing the diagram $M$ into two parts, $M_-$ and $M_+$, one has, say, for $Q \in M_-:

$$\dot{G}(P,Q;\lambda) = -2i \oint_{\gamma_k} G(z,\bar{z},Q;\lambda) [\dot{G}_-(P,z,\bar{z};\lambda)] d\bar{z} + G_z(z,\bar{z},Q;\lambda) \dot{G}_-(P,z,\bar{z};\lambda) dz,$$

$$-2i \oint_{\gamma_k} G(z,\bar{z},Q;\lambda) [\dot{G}_+(P,z,\bar{z};\lambda)] d\bar{z} + G_z(z,\bar{z},Q;\lambda) \dot{G}_+(P,z,\bar{z};\lambda) dz = 0.$$ 

These two relations together with (3.8), (3.9) imply (3.3).

To prove (3.5) we notice (leaving the detailed proof to the reader) that the infinitesimal horizontal shift of a zero $P_k$ of the differential $\omega$ (or, equivalently, the variation of the interaction time $\tau_k$) is the same as the insertion (removal) of the infinitesimal horizontal cylinders along the circumferences $A_k$, $A'_k$ and $C_k$ of the three cylinders of the diagram $M$ meeting at $P_k$. It is easy to show that the variation of the resolvent kernel under each such insertion (removal) is given by

$$4\Im \left\{ \oint_{\gamma} \omega \right\}.$$
where the $\gamma$ is the cycle of the insertion (removal). The orientation of the cycle $\gamma$ depends on its position with respect to the point $P_k$ (from the left or from the right).

It should also be noticed that the sum $\pm A_k \pm A_k' \mp C_k$ is homologous to a small circular contour surrounding the zero $P_k$ and (3.5) could also be proved using real analyticity of the resolvent kernel with respect to the local parameter $\sqrt{z - z_k}$ (cf. the proof of formula (4.24) in [22]).

The proof of (3.4) is similar to the proof of the formula (4.20) in [22]. We leave it to the reader.

### 3.3 Variational formulas for regularized determinant

Choose a canonical basis of $a$ and $b$-periods on the compact Riemann surface $M$, the corresponding basis of normalized holomorphic differentials $\{v_k\}$: $\int_{b_j} v_k = \delta_{jk}$ and introduce the corresponding matrix of $b$-periods

$$B = |\int_{b_j} v_k|_{j,k=1,...,g},$$

the prime form $E(P, Q)$, the canonical meromorphic bidifferential

$$W(P, Q) = d_P d_Q \log E(P, Q),$$

and the Bergman projective connection $S_B$ (see [8]). Denote by $S_\omega$ the projective connection defined via

$$\left\{ \int_{P} \omega, x(P) \right\},$$

where the braces denote the Schwarzian derivative.

The following theorem gives the variational formulas for the regularized determinant with respect to moduli.

**Theorem 5.** Let

$$\tilde{Q} = \frac{\det \Delta_{\tilde{m}}}{\det \mathfrak{ZB}}, \quad Q = \frac{\det(\Delta, \tilde{\Delta})}{\det \mathfrak{ZB}}.$$

Then the following variational formulas hold:

\[
\frac{\partial \log Q}{\partial \theta_k} = \frac{\partial \log \tilde{Q}}{\partial \theta_k} = -\frac{1}{6\pi} \Re \left\{ \int_{\gamma_k} \frac{S_B - S_\omega}{\omega} \right\}, \quad k = 1, \ldots, 3g + n - 3; \tag{3.10}
\]

\[
\frac{\partial \log Q}{\partial h_k} = \frac{\partial \log \tilde{Q}}{\partial h_k} = \frac{1}{6\pi} \Re \left\{ \int_{b_k} \frac{S_B - S_\omega}{\omega} \right\}, \quad k = 1, \ldots, g; \tag{3.11}
\]

\[
\frac{\partial \log Q}{\partial \tau_k} = \frac{\partial \log \tilde{Q}}{\partial \tau_k} = \frac{1}{6\pi} \Re \left\{ \int_{A_k \pm A'_k \mp C_k} \frac{S_B - S_\omega}{\omega} \right\}. \tag{3.12}
\]

Although methods of Fay’s memoir [8] allows to derive Theorem 5 from Proposition 2 in the same manner as [22, Theorem 9] was derived from [22, Proposition 2], we decided to use another approach, which is shorter and more transparent than that of [22]. We rely on the contour integral representation of the operator-zeta function and the variations of individual eigenvalues of the Laplacian $\Delta^m$, see Lemma 6 below.
Lemma 6. Let $\lambda_j$ be an eigenvalue of $\Delta \tilde{m}$ and let $\phi_j$ be the corresponding (real-valued) normalized eigenfunction. The one-form

$$\Omega_j = (\partial_z \phi_j(z, \bar{z}))^2 dz + \frac{\lambda_j}{4} \phi_j(z, \bar{z})^2 d\bar{z}$$  \hspace{1cm} (3.13)

is closed in the flat part of $(\mathcal{M}, \tilde{m})$ outside the conical singularities. One has the following variational formulas:

$$\frac{\partial \lambda_j}{\partial \theta_k} = 4 \Re \left\{ \phi_{\gamma_k} \Omega_j \right\},$$ \hspace{1cm} (3.14)

$$\frac{\partial \lambda_j}{\partial h_k} = -4 \Re \left\{ \int_{b_k} \phi \Omega_j \right\},$$ \hspace{1cm} (3.15)

$$\frac{\partial \lambda_j}{\partial \tau_k} = 4 \Im \left\{ \int_{\pm A_k \pm A_k' + C_k} \phi \Omega_j \right\}.$$ \hspace{1cm} (3.16)

Proof of Lemma 6. All statements immediately follow from Proposition 3 (cf. [8], p. 53 and 3.17) and the relation

$$\hat{\lambda}_n = \int_{\mathcal{M}} \text{Res} \left\{ (\lambda - \lambda_n) \hat{G}(x, y; \lambda); \lambda = \lambda_n \right\} \Big|_{y=x} d\tilde{m}(x).$$

However, Lemma 6 can also be proved independently. Let us omit the index $j$ and denote the eigenvalue by $\lambda$ and the corresponding (real-valued) normalized eigenfunction by $\phi$. For instance, to prove (3.14) observe (cf. (3.8) and (3.9)) that the derivative $\dot{\phi}$ of $\phi$ with respect to $\theta_k$ has the jump $i(\dot{\phi}_z - \dot{\phi})$ on the contour $\gamma_k$, whereas $\dot{\phi}_z$ has there the jump $i(\phi_{zz} - \phi_{z\bar{z}})$. Denote by $\tilde{M}$ the surface $\mathcal{M}$ cut along the contour $\gamma_k$. We have

$$\int_{\tilde{M}} \phi \dot{\phi} = \frac{1}{\lambda} \int_{\mathcal{M}} \Delta \tilde{m} \phi \dot{\phi} = \frac{1}{\lambda} \left\{ 2i \int_{\partial \tilde{M}} \phi \dot{\phi} d\bar{z} + \phi \dot{\phi}_z dz \right\}$$

$$= \frac{1}{\lambda} \left\{ -2 \int_{\gamma_k} \phi_z (\dot{\phi}_z - \dot{\phi}) d\bar{z} + \phi (\phi_{zz} - \phi_{z\bar{z}}) dz + \hat{\lambda} + \lambda \int_{\tilde{M}} \phi \dot{\phi} \right\}$$

Now (3.14) follows from the relations

$$\phi_z \phi_z d\bar{z} - (\phi_z)^2 d\bar{z} + \phi \phi_{zz} dz - \phi \phi_{z\bar{z}} dz = d(\phi \dot{\phi}_z) - (\phi_z)^2 dz - \phi \phi_{z\bar{z}} d\bar{z} - (\phi_z)^2 d\bar{z} - \phi \phi_{z\bar{z}} dz$$

and

$$\phi_{z\bar{z}} = \frac{\lambda}{4} \phi;$$

the latter one, of course, holds only in the flat part of $(\mathcal{M}, \tilde{m})$. \[ \square \]

Proof of Theorem 5. From now on $\lambda$ stands for the spectral parameter (we assume that it is real and negative), $\{\lambda_k\}$ is the spectrum of $\Delta \tilde{m}$, $z$ is the complex variable of integration which at some points also becomes the spectral parameter (one of the arguments of the resolvent kernel), $x$ and $y$ will denote the (flat) complex local coordinates of points near the contour $\gamma_k$. We start from the following integral representation of the zeta-function of the operator $\Delta \tilde{m} - \lambda$ through the trace of the second power of the resolvent:

$$s \zeta(s + 1; \Delta \tilde{m} - \lambda) = \frac{1}{2\pi i} \int_{\Gamma_{\lambda}} (z - \lambda)^{-s} \text{Tr} ((\Delta \tilde{m} - z)^{-2}) dz,$$ \hspace{1cm} (3.17)
where \( \Gamma_\lambda \) is the contour connecting \(-\infty + i \epsilon \) with \(-\infty - i \epsilon \) and following the cut \((-\infty, \lambda)\) at the (sufficiently small) distance \(\epsilon > 0\).

Differentiating this formula with respect to \( \theta_k \) (dot stands for such a derivative) and making use of (3.14), we get

\[
\begin{align*}
\dot{s} \zeta(s + 1, \Delta \tilde{m} - \lambda) &= -\frac{1}{\pi i} \int_{\Gamma_\lambda} (z - \lambda)^{-s} \sum_{\lambda_n > 0} \frac{\dot{\lambda}_n}{(\lambda_n - z)^3} dz \\
&= -\frac{4}{\pi i} \int_{\Gamma_\lambda} (z - \lambda)^{-s} \sum_n \Re \left\{ \oint_{\gamma_k} \left( \partial_x \phi_n(x, \bar{x}) \right)^2 dx + \frac{\lambda}{(\lambda_n - z)^3} \phi_n(x, \bar{x})^2 d\bar{x} \right\}.
\end{align*}
\]

(3.18)

One can assume that the contour \( \gamma_k \) is parallel to the imaginary axis and, therefore, \( \Re \oint_{\gamma_k} \phi_n^2 d\bar{x} = 0 \) (the latter trick does not work when one differentiates with respect to other moduli \( h_k, \tau_k \), in these cases the proof gets a little bit longer) and the right hand side of (3.18) can be rewritten as

\[
\begin{align*}
-\frac{2}{\pi i} \oint_{\gamma_k} \int_{\Gamma_\lambda} (z - \lambda)^{-s} \sum_n \left( \partial_x \phi_n(x, \bar{x}) \right)^2 (\lambda_n - z)^3 dz - \frac{2}{\pi i} \oint_{\gamma_k} \int_{\Gamma_\lambda} \left( \partial_x \phi_n(x, \bar{x}) \right)^2 (\lambda_n - z)^3 d\bar{x} dz.
\end{align*}
\]

(3.19)

Using the standard resolvent kernel representation

\[
G(x, y; z) = \sum_n \frac{\phi_n(x, \bar{x})\phi_n(y, \bar{y})}{\lambda_n - z},
\]

where summation is understood in the sense of the theory of distributions, one can easily identify the sum under the first (resp. the second) integral with \( \frac{1}{\pi} \left( \frac{d^2}{(dz)^2} G''_{xy}(x, y; z) \right) \bigg|_{y=x} \) (resp. \( \frac{1}{\pi} \left( \frac{d}{dz} G''_{xy}(x, y; z) \right) \bigg|_{y=x} \)). It should be noted that although the resolvent kernel (as well as its second \( xy \)-derivative) is singular at the diagonal \( x = y \), after differentiation with respect to the spectral parameter this singularity disappears. Using Theorem 2.7 from Fay’s memoir [8], we get

\[
\left( \frac{d^2}{(dz)^2} G''_{xy}(x, y; z) \right) \bigg|_{y=x} = \frac{d^2}{(dz)^2} \Phi(x, z);
\]

note that in [8 (2.32)] one should take \( r = |x - y|, H_0 = 1, \) and \( H_1 = 0 \) as the metric \( \tilde{m} \) is flat in a vicinity of the contour \( \gamma_k \). Clearly, in the right hand side of (3.18) the sum under the second integral equals to

\[
\frac{d^2}{(dz)^2} \Phi(x, \bar{z}).
\]

Integration by parts in (3.18) (and the change of variable \( s + 1 \to s \)) leads to

\[
\dot{\zeta}(s; \Delta \tilde{m} - \lambda) = -\frac{1}{\pi i} \oint_{\gamma_k} \int_{\Gamma_\lambda} (z - \lambda)^{-s} \left[ \frac{d}{dz} \Phi(x, z) dx + \frac{d}{dz} \Phi(x, \bar{z}) d\bar{x} \right] dz.
\]

Shrinking the contour \( \Gamma_\lambda \) to the half-line \((-\infty, \lambda)\), we obtain

\[
\dot{\zeta}(s; \Delta \tilde{m} - \lambda) = -\frac{2\sin(\pi s)}{\pi} \int_{-\infty}^\lambda \oint_{\gamma_k} (\lambda - t)^{-s} \left[ \frac{d}{dt} \Phi(x, t) dx + \frac{d}{dt} \Phi(x, t) d\bar{x} \right] dt.
\]

(3.20)
We differentiate (3.20) with respect to \( s \) and set \( s = 0 \) and \( \lambda = 0 \). As a result we get
\[
\zeta'(0, \Delta \vec{m}) = -2 \oint_{\gamma_k} \Phi(x,t) \bigg|_{t=0}^{t=-\infty} dx + \Phi(x,t) \bigg|_{t=-\infty}^{t=0} d\bar{x}
\] (3.21)
\[
= -2 \oint_{\gamma_k} \left( \frac{1}{24\pi} S_B(x) - \frac{1}{4} \sum_{\alpha,\beta=1}^{g} (\Im B)_{\alpha\beta}^{-1} v_\alpha(x)v_\beta(x) \right) dx + \left( \cdots \right) d\bar{x}
\] (3.22)
which is the same as (3.10). To pass from (3.21) to (3.22) we used the classical Lemma 7 given below (cf. [8], p. 30).

Lemma 7. Let, as before, \( G(x,y;\lambda) \) be the resolvent kernel for the operator \( \Delta \vec{m} \). Define the Green function \( G(x,y) \) of the operator \( \Delta \vec{m} \) via the expansion
\[
G(x,y;\lambda) = \frac{1}{\text{Area}(\mathcal{M}, \vec{m})} \frac{1}{\lambda} + G(x,y) + O(\lambda), \quad \lambda \to 0.
\] (3.23)
Then \( G''_{xy}(\cdot, \cdot) \) is a meromorphic bidifferential with unique double pole at the diagonal \( x = y \), related to the Bergman bidifferential \( W(x,y) \) via
\[
4\pi G''_{xy}(x,y) = W(x,y) - \pi \sum_{i=1}^{g} \Im B_{ij}^{-1} v_i(x)v_j(y),
\]
where \( v_1, \ldots, v_g \) are the normalized holomorphic differentials on the compact Riemann surface \( \mathcal{M} \). In particular, we have
\[
\left[ 4\pi G''_{xy}(x,y) - \frac{1}{(x-y)^2} \right] \bigg|_{y=x} = \frac{1}{6} S_B(x) - \pi \sum_{i=1}^{g} \Im B_{ij}^{-1} v_i(x)v_j(x),
\]
where \( S_B \) is the Bergman projective connection.

Proof. Clearly, the Green function (symmetric with respect to its both arguments) is the (unique) solution to the problem
\[
\begin{align*}
\Delta \vec{m} G(x,y) &= -\frac{1}{\text{Area}(\mathcal{M}, \vec{m})} \quad \text{for } x \neq y, \\
G(x,y) &\sim \frac{1}{2\pi} \log |x-y| \quad \text{as } x \to y.
\end{align*}
\]
Thus, \( \partial_y G''_{xy} = 0 \) for \( x \neq y \) and \( 4\pi G''_{xy}(x,y) = \frac{1}{(x-y)^2} + O(1) \) as \( y \to x \). This implies the equation
\[
4\pi G''_{xy}(x,y) = W(x,y) + \sum_{i,j=1}^{g} c_{ij} v_i(x)v_j(y)
\] (3.24)
with some constants \( c_{ij} \). Using Stokes theorem, it is easy to show that
\[
v.p. \int_M G''_{xy}(x,y)v_i(x) = 0, \quad i = 1, \ldots, g.
\] (3.25)
Plugging (3.24) in the orthogonality conditions (3.25) and using Stokes theorem once again, one gets the relations
\[
c_{ij} = -\pi (\Im B)_{ij}^{-1}, \quad i, j = 1, \ldots, g.
\]
\[\square\]
Remark 2. For other moduli \((h_k, \tau_k)\) the trick with choosing the contour of integration parallel to the imaginary axis is impossible and one has to work with the additional term
\[
\sum \frac{\lambda_n (\phi_n(x, \bar{x}))^2}{4 (z - \lambda_n)^2} = \frac{1}{2} \left. \left( \frac{d^2}{(dz)^2} G''_{x\bar{x}}(x, y; z) \right) \right|_{y=x}.
\]
To interchange the differentiation with respect to \(z\) and pass to the limit \(y \to x\) one should make use of the following corollary of [8, Theorem 2.7]:
\[
\left. \left( \frac{d^2}{(dz)^2} G''_{x\bar{x}}(x, y; z) \right) \right|_{y=x} = \frac{d^2}{(dz)^2} \left\{ \left( G''_{x\bar{x}}(x, y; z) - \frac{1}{16\pi} z \log |x - y|^2 - \frac{1}{8\pi} z \left( \log \frac{1}{2} \sqrt{z + \gamma - 1} \right) \right) \right|_{y=x} \right\}.
\]
After the same operations as before this term gives rise to the expressions
\[
\Re \left[ \frac{1}{\text{Area}(M, \tilde{m})} \oint_{b_k} d\bar{\ell} \right] \quad \text{or} \quad \frac{1}{\text{Area}(M, \tilde{m})} \oint_{\pm A_k \pm \tilde{A}_k + C_k} d\bar{\ell}.
\]
Both of them vanish.

Remark 3. For non Friedrichs self-adjoint extensions of the Laplacian on \((M, \tilde{m})\) \(\lambda = 0\) is not an eigenvalue and (3.23) is no longer true. Determinants of such extensions were studied in [10].

4 Bergman tau-function on Mandelstam diagrams and explicit formulas for regularized determinant

In this section we show that a solution to the system of equations in partial derivatives \((3.10, 3.11, 3.12)\) can be found explicitly in terms of certain canonical objects related to the underlying Riemann surface \(M\) (theta-functions, prime-forms) and the divisor of the meromorphic differential \(\omega\). This leads to an explicit formula for the regularized determinant \(\text{det}(\Delta, \tilde{\Delta})\) (up to moduli independent multiplicative constant).

We construct the above mentioned solution as the modulus square of the function \(\tau\) defined on the space of Mandelstam diagrams of a given genus. (More precisely, only some integer power of \(\tau\) is single-valued on the space of diagrams, the function \(\tau\) itself is defined up to a unitary factor.)

We start with definition of the function \(\tau\). Note that it is a straightforward generalization of the Bergman tau-function on the moduli space of Abelian differentials [22] (i. e. the moduli space of pairs \((X, \omega)\), where \(X\) is a compact Riemann surface, and \(\omega\) is a holomorphic one-form on \(X\)) to the case of a meromorphic one-form \(\omega\) with pure imaginary periods and simple poles with (fixed) real residues. This generalization (along with many others) was also recently discussed in [17].

The cases of genus \(g = 0, g = 1\) and \(g \geq 2\) should be considered separately, the first two are pretty elementary and do not involve somewhat complicated auxiliary objects.

Genus zero case. Let the Riemann surface \(M\) have genus zero. In this case the Mandelstam diagram \(\Pi\) has no interior slits. The Riemann surface \(M\) is biholomorphically equivalent to the Riemann sphere \(\mathbb{C}P^1\), let \(z\) be the uniformizing parameter which came from \(\mathbb{C} = \mathbb{C}P^1 \setminus \infty\). The canonical meromorphic bidifferential is given by
\[
W(P, Q) = \frac{dz(P) \, dz(Q)}{(z(P) - z(Q))^2}.
\]
Assume that the circles $O_1, \ldots, O_{n_-}$ correspond to the left cylindrical ends of $\mathcal{M}$, i.e. $\cup_{1 \leq \ell \leq n_-} O_\ell$ is the cross-section $\{ p \in \mathcal{M} : x = -R \}$. Then there are $n_+ = n - n_-$ circles $O_{n_-+1}, \ldots, O_n$ corresponding to the right cylindrical ends of $\mathcal{M}$. Let $P_1^-$ with $k = 1, \ldots, n_-$ and $P_1^+$ with $j = 1, \ldots, n_+$ be the corresponding points at infinity of the diagram $\mathcal{M}$ or, equivalently, the poles of the meromorphic differential $\omega$ with residues $-\frac{|O_1|}{2\pi}$ and $-\frac{|O_{n_-+1}|}{2\pi}$ respectively. Let also $R_1, \ldots, R_{n_-2}$ be the zeros of the meromorphic differential $\omega$ or, equivalently, the end points of the semi-infinite slits of the diagram $\mathcal{M}$.

Introduce the local parameters
\[
\zeta_k^- = \exp(2\pi z/|O_k|) \quad \text{(resp. } \zeta_j^+ = \exp(-2\pi z/|O_{n_-+j}|)) \quad (4.1)
\]
in vicinities of the poles $P_k^-$ (resp. $P_j^+$) of the differential $\omega$ and
\[
\zeta_\ell = \sqrt{z - z(R_\ell)} \quad (4.2)
\]
in vicinities of the zeros $R_\ell$ of $\omega$. We call the parameters $(4.1), (4.2)$ distinguished. In what follows we denote by $W(R_\ell, \cdot)$ the meromorphic one-form on the Riemann surface $\mathcal{M}$
\[
\frac{dW(P_\cdot, \cdot)}{d\zeta(P)} \bigg|_{P=R_\ell},
\]
where $\zeta$ is the distinguished local parameter in a vicinity of $R_\ell$; the quantities $W(P_\pm, \cdot)$ have similar meaning. Introduce the function $\tau$ on the space of Mandelstam diagrams via
\[
\tau^{12} = \frac{1}{\omega^2(\cdot)} \frac{\prod_{k=1}^{n_-} W(P_k^-, \cdot) \prod_{j=1}^{n_+} W(P_j^+, \cdot)}{\prod_{l=1}^{n_-} W(R_\ell, \cdot)}. \quad (4.3)
\]

Clearly, the right hand side of $(4.3)$ is a holomorphic function on the Riemann surface $\mathcal{M}$ and, therefore, a constant (depending on moduli).

**Genus one case.** Let the Riemann surface $\mathcal{M}$ have genus one. In this case the Mandelstam diagram $\mathcal{M}$ has one interior slit and the number of poles of the differential $\omega$ (i.e. the points at infinity of the diagram $\mathcal{M}$) equals to the number of zeros of $\omega$ (i.e. the endpoints of the slits of the diagram $\mathcal{M}$). For the poles and zeros we keep the same notation $P_k^\pm, R_l$ as before. Let $B$ be the $b$-period of the normalized $(f_a v = 1)$ differential $v$ on the marked Riemann surface $(\mathcal{M}, \{a, b\})$. Let
\[
v(R_\ell) = \frac{v(P)}{d\zeta(P)} \bigg|_{P=R_\ell},
\]
where $\zeta$ is the distinguished local parameter near $R_\ell$. The quantities $v(P_k^\pm)$ are defined similarly. Define the function $\tau$ via
\[
\tau^{12} = \left[ \Theta_1'(0 \mid B) \right]^8 \frac{\prod_{k=1}^{n_-} v(P_k^-) \prod_{j=1}^{n_+} v(P_j^+)}{\prod_{l=1}^{n_-} v(R_\ell)}, \quad (4.4)
\]
where $\Theta_1$ is the first Jacobi's theta-function.

**Case of genus $g \geq 2$.** Let the Riemann surface $\mathcal{M}$ have genus $g \geq 2$. Following $[\S]$, introduce the (multivalued) $g(g - 1)/2$-differential
\[
C(P) = \frac{1}{W[v_1, v_2, \ldots, v_g](P)} \sum_{\alpha_1, \ldots, \alpha_g=1}^{g} \frac{\partial^{g \Theta(K^P)}}{\partial z_{\alpha_1} \ldots \partial z_{\alpha_g}} v_{\alpha_1} \ldots v_{\alpha_g}(P),
\]
\end{document}
where \( \{v_1, \ldots, v_g\} \) is the normalized basis of holomorphic differentials on \( M \), \( W \) is the Wronskian determinant of the holomorphic differentials, \( K^P \) is the vector of Riemann constants, \( \Theta \) is the theta-function built from the matrix \( B \) of the \( b \)-periods of the Riemann surface \( M \). Let \( E(P, Q) \) be the prime-form on \( M \) (see [8]).

It is convenient to denote the zeros and poles of the meromorphic one-form \( \omega \) by \( D_l \).

The divisor of the one-form \( \omega \) can be written as

\[
(\omega) = \sum_l d_l D_l,
\]

where \( d_l = 1 \) if \( D_l \) is a zero and \( d_l = -1 \) if \( D_l \) is a pole of \( \omega \).

Define the function \( \tau \) via

\[
\tau = \mathcal{F}^{2/3} e^{-\frac{\pi i}{6} \langle r, B r \rangle} \prod_{m<n} \{E(D_m, D_n)\}^{d_m d_n/6},
\]

where the (scalar)

\[
\mathcal{F} = [\omega(P)]^{(g-1)/2} e^{-\pi i \langle r, K^P \rangle} \prod_m [E(P, D_m)]^{(1-g)d_m/2} \mathcal{C}(P)
\]

is independent of the point \( P \) of the Riemann surface \( M \) and the integer vector \( r \) is defined by the equality

\[
A((\omega)) + 2K^P + B r + q = 0;
\]

here \( q \) is another integer vector and the initial point of the Abel map \( A \) coincides with \( P \). If one argument (or both) of the prime-form coincides with some point \( D_l \) then the prime-form is computed with respect to the distinguished local parameter at this point.

**Remark 4.** If \( n_- = n_+ \) and there is a one-to-one correspondence between the sets \( \{O_k\}_{k=1}^{n_-} \) and \( \{O_j\}_{j=n_-+1}^{n} \), then as \( \bar{M} \) one take the union \( \bigcup_{x=1}^{n_-} \mathbb{R} \times O_x \) of \( n/2 \) infinite cylinders. As a result the right hand sides of (4.3), (4.4), and (4.5) turns out to be invariant under the horizontal shifts of the diagram \( z \mapsto z + C \) or, what is the same, independent of the choice of the initial moment of time \( \tau_0 = 0 \).

The following theorem states that the logarithm of the modulus square of the just introduced function \( \tau \) has the same derivatives with respect to moduli as the quantity \( \log \frac{\det(\Delta, \Delta^\vee)}{\det 3B} \).

**Theorem 6.** Then the following variational formulas hold:

\[
\frac{\partial \log |\tau|^2}{\partial \theta_k} = -\frac{1}{6\pi} \Re \left\{ \oint_{\gamma_k} \frac{S_B - S_\omega}{\omega} \right\}, \quad k = 1, \ldots, 3g + n - 3; \tag{4.6}
\]

\[
\frac{\partial \log |\tau|^2}{\partial h_k} = \frac{1}{6\pi} \Re \left\{ \oint_{b_k} \frac{S_B - S_\omega}{\omega} \right\}, \quad k = 1, \ldots, g; \tag{4.7}
\]

\[
\frac{\partial \log |\tau|^2}{\partial \tau_k} = -\frac{1}{6\pi} \Im \left\{ \oint_{A_k \pm A_k^\vee \pm C_k} \frac{S_B - S_\omega}{\omega} \right\}. \tag{4.8}
\]
Proof. The proof is completely similar to the proofs of [22, Theorems 6 and 7]. First, one has to derive variational formulas (under variations of the moduli $\theta_k, \tau_k, \text{ and } h_k$) for the basic objects on the compact Riemann surface $M$ which appear as ingredients in the explicit expression for the function $\tau$ (i.e. the basic holomorphic differentials, the matrix of $b$-periods, the canonical meromorphic bidifferential, the prime-form, the vector of the Riemann constants, and the multi-valued differential $C$). Then one has to check (4.6)–(4.8) via direct calculation. We decided not to repeat this rather long calculation here, we only sketch the proof in a relatively simple case of a low genus curve, where most of the technicalities disappear. For instance, let us prove (4.6) in case $g = 1$.

Choose a canonical basis $\{a, b\}$ of cycles on $M$ and introduce the normalized holomorphic differential $v$ such that

$$\int_a v = 1 \quad \text{and} \quad \int_b v = B.$$

Take $P \in \Pi$, then in vicinity of $P \in M$ the ratio of the two one-forms $\frac{v}{dz}$ defines a scalar function. Denote the value of this function at $P$ by $v(P)$. For a fixed $P$ this value still depends on the moduli $\theta_k, h_k, \tau_k$. Using the same idea as in the proof of Proposition 2 (see also [22, Proof of Theorem 3]), one can prove the following variational formula for the $v(P)$ with respect to the coordinate $\theta_k$:

$$\frac{\partial v(P)}{\partial \theta_k} = \frac{1}{2\pi} \int_{\gamma_k} \frac{W(\cdot, P)v}{\omega},$$

(4.9)

where $W$ is the Bergman bidifferential and the one form $W(\cdot, P)$ is defined as $\frac{W(\cdot, Q)}{dz(Q)}|_{Q=P}$.

Integrating (4.9) over the $b$-cycle, one gets the following variational formula for the $b$-period:

$$\frac{\partial B}{\partial \theta_k} = i \int_{\gamma_k} \frac{v^2}{\omega},$$

(4.10)

Moreover, since the distinguished local parameters (4.1) at $P_k^-$, $P_j^+$ and (4.2) at $R_l$ are moduli independent, (4.9) implies that

$$\frac{\partial v(P_k^-)}{\partial \theta_k} = \frac{1}{2\pi} \int_{\gamma_k} \frac{W(\cdot, P_k^-)v}{\omega},$$

(4.11)

$$\frac{\partial v(P_j^+)}{\partial \theta_k} = \frac{1}{2\pi} \int_{\gamma_k} \frac{W(\cdot, P_j^+)v}{\omega},$$

(4.12)

and

$$\frac{\partial v(R_l)}{\partial \theta_k} = \frac{1}{2\pi} \int_{\gamma_k} \frac{W(\cdot, R_l)v}{\omega},$$

(4.13)

where, say, $v(P_k^-) = \frac{v}{dz(P)}|_{P_k}$ and $W(\cdot, R_l) = \frac{W(\cdot, Q)}{dz(Q)}|_{Q=R_l}$, etc.

Now using (4.11)–(4.13) and the well-known formula

$$W(z_1, z_2) = \left[\Psi \left( \int_{z_1}^{z_2} v \right) - \frac{4i\pi}{3} \frac{d}{dB} \log \Theta_1(0 \| B) \right] v(z_1)v(z_2)$$

for the Bergman bidifferential on an elliptic curve (see, e.g., [7]), where $\Psi$ is the Weierstrass $\Psi$-function, we arrive at

$$\partial_{\theta_k} \log \frac{\prod_{k=1}^{n-k} v(P_k^-) \prod_{j=1}^{n-j} v(P_j^+)}{\prod_{l=1}^{n} v(R_l)}$$
\begin{align*}
= \frac{1}{2\pi} \int_{\gamma_k} v(Q) \left\{ \sum_{k=1}^{n_-} \frac{W(Q,P_k^-)}{v(P_k^-)} + \sum_{j=1}^{n_+} \frac{W(Q,P_j^+)}{v(P_j^+)} - \sum_{l=1}^{n} \frac{W(Q,R_l)}{v(R_l)} \right\} \\
= \frac{1}{2\pi} \int_{\gamma_k} \frac{v^2(Q)}{\omega(Q)} \left( \sum_{k=1}^{n_-} \Psi(\int_{P_k^-}^{Q} v) + \sum_{j=1}^{n_+} \Psi(\int_{P_j^+}^{Q} v) - \sum_{l=1}^{n} \Psi(\int_{R_l}^{Q} v) \right). 
\end{align*}

(4.14)

Consider the meromorphic function \( R' = \frac{\omega}{v} \) on \( \mathcal{M} \). (Clearly, it can be considered as the derivative of the (mulivalued) map \( \xi = \int_{v}^{P} v \mapsto R(\xi) = \int_{v}^{P} \omega \). Observe that the expression in the square brackets in (4.14) coincides with \( \frac{d}{d\xi} \left( \frac{R''(\xi)}{R'(\xi)} \right) \).

Therefore, using integrating by parts, (4.14) can be rewritten as

\begin{align*}
\frac{1}{2\pi} \int_{\gamma_k} \frac{1}{R'(\xi)} \frac{d}{d\xi} \left( \frac{R''(\xi)}{R'(\xi)} \right) d\xi = \frac{1}{2\pi} \int_{\gamma_k} \frac{(R''(\xi))^2}{(R'(\xi))^3} d\xi = \frac{1}{\pi} \int_{\gamma_k} \frac{\{R,\xi\}}{R'(\xi)} d\xi 
= \frac{1}{\pi} \int_{\gamma_k} \frac{\{\int_{v}^{P} \omega, \cdot \} - \{\int_{v}^{P} v, \cdot \}}{\omega},
\end{align*}

(4.15)

where \( \{\cdot, \cdot\} \) denotes the Schwarzian derivative. The integrand in (4.16) is a meromorphic one-form: the ratio of the difference of two projective connections (this difference gives a quadratic differential) and a meromorphic one-form.

Moreover, using (4.10), we get

\[ \partial_{\theta_k} \log \left[ \Theta_1'(0 \mid \mathcal{B}) \right]^8 = 8i \frac{\partial \log \Theta_1'(0 \mid \mathcal{B})}{\partial \mathcal{B}} \int_{\gamma_k} \frac{v^2}{\omega} \]

and, therefore,

\[ \partial_{\theta_k} \log (\tau^{12}) = \frac{1}{\pi} \int_{\gamma_k} \frac{\{\int_{v}^{P} \omega, \cdot \} - \{\int_{v}^{P} v, \cdot \} - 8i\pi \frac{\partial \log \Theta_1'(0 \mid \mathcal{B})}{\partial \mathcal{B}} \cdot v^2}{\omega}, \]

(4.17)

where \( \tau \) is from (4.4). It is known (see, e. g., [7]) that the expression in square brackets in (4.17) coincides with the Bergman projective connection. Therefore

\[ \partial_{\theta_k} \log \tau = -\frac{1}{12\pi} \int_{\gamma_k} \frac{S_B - S_\omega}{\omega}, \]

which proves (4.6).

The following immediate corollary of Theorem 3 is the main result of the present paper.

**Corollary 1.** One has the following explicit expression for the regularized determinant of the Laplacian on the Mandelstam diagram \( \mathcal{M} \):

\[ \det(\Delta, \tilde{\Delta}) = C \det \mathcal{B} |\tau|^2, \]

(4.18)

where \( C \) is moduli independent constant.

**Remark 5.** If the unperturbed diagram \( \mathcal{M} \) is a disjoint union of infinite cylinders then the regularized determinant \( \det(\Delta, \tilde{\Delta}) \) is invariant with respect to horizontal shifts of the diagram \( \mathcal{M} \) (i. e. the choice of the initial moment of time \( \tau_0 \)). The same is, of course, true for the right hand side of (4.18), cf. Remark 4.
A Appendix.

A.1 Proof of Lemmas 1 and 2

Proof of Lemma 1. The proof is based on well-known methods of the theory of elliptic boundary value problems, see e.g. [19, 20, 25]. Recall that a bounded operator is said to be Fredholm if its kernel and cokernel are finite dimensional and its range is closed. We will rely on the following lemma due to Peetre, see e.g. [20, Lemma 3.4.1] or [25, Lemma 5.1]:

Let $X, Y$ and $Z$ be Hilbert spaces, where $X$ is compactly embedded into $Z$. Furthermore, let $L$ be a linear continuous operator from $X$ to $Y$. Then the next two assertions are equivalent: (i) the range of $L$ is closed in $Y$ and dim ker $L < \infty$, (ii) there exists a constant $C$, such that

$$\|u; X\| \leq C(\|Lu; Y\| + \|u; Z\|) \quad \forall u \in X. \quad (A.1)$$

Below we assume that $\varrho k$ is the cross-section of a cylindrical end directed to the left (resp. directed to the right). We also set $\varrho k$ if the end is directed to the right. Introduce the weighted Sobolev space and establish the estimate

$$\|u; D \varrho\| \leq C(\|\Delta \varrho - \mu^2 u; L^2_c(M)\| + \|u; L^2(M)\|) \quad (A.3)$$

of type (A.1).

Let $R > 0$ be so large that there are no conical points on $M$ with coordinate $x \notin (-R, R)$. Take some smooth functions $\varrho_k$, $1 \leq k \leq n$, on $M$ satisfying

$$\varrho_k(p) = \begin{cases} 1, & p \in (-\infty, -R - 1) \times O_k \text{ (resp. } p \in (R + 1, \infty) \times O_k), \\ 0, & p \in M \setminus (-\infty, -R) \times O_k \text{ (resp. } p \in M \setminus (R, \infty) \times O_k), \end{cases}$$

if $O_k$ is the cross-section of a cylindrical end directed to the left (resp. directed to the right). We also set $\varrho_0 = 1 - \sum k \varrho_k$, then $\{\varrho_k\}_{k=0}^n$ is a partition of unity on $M$.

Let $L^2_c(\mathbb{R} \times O_k)$ be the weighted space with the norm $\left(\int_{\mathbb{R} \times O_k} |e^\gamma_k u(x, y)|^2 dx \, dy\right)^{1/2}$, where $\gamma_k = -\epsilon$ if the corresponding cylindrical end of $M$ is directed to the left and $\gamma_k = \epsilon$ if the end is directed to the right. Introduce the weighted Sobolev space $H^2_c(\mathbb{R} \times O_k)$ as completion of the set $C^\infty_c(\mathbb{R} \times O_k)$ in the norm

$$\|u; H^2_c(\mathbb{R} \times O_k)\| = \left(\sum_{p+q \leq 2} \|\partial_x^p \partial_y^q u; L^2_c(\mathbb{R} \times O_k)\|^2\right)^{1/2}.$$

For $u \in D \varrho_c(\subset H^1(M))$ we extend $u_k = \varrho_k u$, $1 \leq k \leq n$, to $\mathbb{R} \times O_k$ by zero. Clearly, the right hand side of the equation

$$(-\partial_x^2 + \Delta O_k - \mu^2)u_k = f_k \quad (A.4)$$

is in $L^2_c(\mathbb{R} \times O_k)$. Applying the Fourier-Laplace transform $\mathcal{F}_{\mu = \xi + i \gamma_k}$ we pass from (A.4) to the equation

$$(\Delta O_k - \mu^2 + (\xi + i \gamma_k)^2)\mathcal{F}_{\mu = \xi + i \gamma_k} u_k = \mathcal{F}_{\mu = \xi + i \gamma_k} f_k, \quad \xi \in \mathbb{R}. \quad (A.5)$$
The norm of the inverse of the operator \( \Delta_{O_k} - \mu^2 + (\xi + i\gamma_k)^2 \) in \( L^2(O_k) \) is bounded by the reciprocal of the distance from the parabola

\[
\{ \mu^2 - (\xi + i\gamma_k)^2 : \xi \in \mathbb{R} \} = \{ \mu^2 - (\xi + ie)^2 : \xi \in \mathbb{R} \}
\]

to the spectrum \( \{0, 4\pi^2 \ell^2|O_k|^{-2} : \ell \in \mathbb{N} \} \) of the selfadjoint Laplacian \( \Delta_{O_k} \) on \( O_k \), cf. (A.2). This together with elliptic coercive estimates for \( \Delta_{O_k} \) and the Parseval equality implies

\[
\|u_k; H^2(\mathbb{R} \times O_k)\| \leq c \|(-\partial^2_x + \Delta_{O_k} - \mu^2)u_k; L^2_x(\mathbb{R} \times O_k)\| \tag{A.6}
\]

with an independent of \( u \in H^2(\mathbb{R} \times O_k) \) constant \( c \); moreover, the operator

\[
-\partial^2_x + \Delta_{O_k} - \mu^2 : H^2(\mathbb{R} \times O_k) \rightarrow L^2_x(\mathbb{R} \times O_k)
\]

yields an isomorphism, see e.g. [20, Chapter 5] or [19] for details.

From (2.2) and (A.6) it immediately follows that

\[
\|u; \mathcal{D}_\epsilon\| \leq \sum_{k=0}^n \|g_k u; \mathcal{D}_\epsilon\| \leq \|\Delta_\epsilon - \mu^2\| \mathcal{g}_0 u; L^2(\mathcal{M})\|
\]

\[
+ (1 + |\mu|^2)\|g_0 u; L^2(\mathcal{M})\| + \sum_{k=1}^n \|g_k u; H^2(\mathbb{R} \times O_k)\| \tag{A.7}
\]

\[
\leq \|\Delta_\epsilon - \mu^2\| u; L^2(\mathcal{M})\| + \sum_{k=0}^n \|g_k; \Delta_\epsilon\| u; L^2(\mathcal{M})\| + (1 + |\mu|^2)\|g_0 u; L^2(\mathcal{M})\|.
\]

Here the commutators \([g_k, \Delta_\epsilon]\) are first order differential operators with smooth coefficients supported on a smooth compact part of \( \mathcal{M} \). Local elliptic coercive estimates imply

\[
\|[g_k, \Delta_\epsilon] u; L^2(\mathcal{M})\| \leq C \|\eta(\Delta_\epsilon - \mu^2) u; L^2(\mathcal{M})\| + \|\eta u; L^2(\mathcal{M})\|, \tag{A.8}
\]

where \( \eta \in C^\infty_c(\mathcal{M}) \) is such that \( \eta[g_k, \Delta_\epsilon] = [g_k, \Delta_\epsilon] \) and \( \eta \mathcal{g}_0 = \mathcal{g}_0 \). Now the estimate (A.3) follows from (A.7) and (A.8). It remains to note that compactness of the embedding \( \mathcal{D}_\epsilon \hookrightarrow L^2(\mathcal{M}) \) is a consequence of the compactness of

\[
H^2_x(\mathbb{R} \times O_k) \ni g_k u \mapsto g_k u \in L^2(\mathbb{R} \times O_k), \quad \mathcal{D} \ni \mathcal{g}_0 u \mapsto \mathcal{g}_0 u \in L^2(\mathcal{M}),
\]

where the domain \( \mathcal{D} \) of the selfadjoint Friedrichs extension of Dirichlet Laplacian on \( \mathcal{M}_R = \{p \in \mathcal{M} : |x| \leq R \} \) is compactly embedded into \( L^2(\mathcal{M}_R) \).

The above argument also implies that the graph norm (2.2) in \( \mathcal{D}_\epsilon \) is equivalent to the norm

\[
\|u; \mathcal{D}_\epsilon\| \asymp \|\mathcal{g}_0 u; \mathcal{D}\| + \sum_{k=1}^n \|g_k u; H^2_x(\mathbb{R} \times O_k)\|, \tag{A.9}
\]

and the space \( \mathcal{D}_\epsilon \) consists of all elements \( u \in H^1_x(\mathcal{M}) \) with finite norm (A.9).

In order to see that the cokernel of the operator (2.3) is finite-dimensional, one can apply a similar argument to the adjoint \( m \)-sectorial operator \( (\Delta_\epsilon)^* \) in \( L^2(\mathcal{M}) \). In particular, it turns out that the graph norm of \( (\Delta_\epsilon)^* \) is equivalent to the norm (A.9) and \( \mathcal{D}_\epsilon \) is the domain of \( (\Delta_\epsilon)^* \).

We have proved that the operator (2.3) is Fredholm if (A.2) holds true. Now we assume that for some \( \xi \in \mathbb{R} \) the number \( \mu^2 - (\xi + ie)^2 \) coincides with an eigenvalue \( \lambda \) of \( \Delta_{O_k} \) and show that the operator (2.3) is not Fredholm.
For instance, let \( O_k \) correspond to a cylindrical end directed to the right. Introduce a cutoff function \( \chi \in C^\infty(\mathbb{R}) \) such that \( \chi(x) = 1 \) for \( |x - 3| \leq 1 \) and \( \chi(x) = 0 \) for \( |x - 3| \geq 2 \). We set \( u_\ell(p) = 0 \) for \( p \in \mathcal{M} \setminus (R, \infty) \times O_k \) and

\[
u_{\ell}(x, y) = g_{k}(x, y)\chi(x/\ell) \exp(i(x(\xi + i\epsilon))\Phi(y), \quad (x, y) \in (R, \infty) \times O_k,
\]

where \( \Delta_{O_k} \Phi = \lambda \Phi \). Straightforward calculations show that

\[
\| (\Delta_\epsilon - \mu^2) u_\ell; L^2_{\ell}(M) \| \leq C, \quad \| u_\ell; L^2(M) \| \leq C, \quad \| u_\ell; D_\epsilon \| \to \infty
\]
as \( \ell \to +\infty \). Thus the sequence \( \{u_\ell\} \) violates the estimate \((A.3)\) and the operator \((2.3)\) is not Fredholm.

\[\Box\]

**Proof of Lemma 2.** As the result is essentially well-known, see e.g. [20, Chapter 5] or [19], we only give a sketch of the proof. The notations below are the same as in the proof of Lemma 1. Let \( u = (\Delta_0 - \mu^2)^{-1} f \). Then \( u_k = g_k u \in H^2(R \times O_k), 1 \leq k \leq n \), is a (unique) solution to the equation \((A.4)\) with right hand side \( f_k = g_k f - |\Delta, g_k| u \), where \( f_k \) is extended to \( \mathbb{R} \times O_k \) by zero. The inclusion \( f \in L^2(M) \) implies that the function \( \xi \mapsto f_k(\xi) = \mathcal{F}_{\xi \to x} f_k(\xi) \in L^2(\partial \Omega_k) \) is analytic in the strip \( |3\xi| < \epsilon \) with boundary values satisfying \( \int_{\mathbb{R}} \| \hat{f}_k(\xi \pm i\ell) \| L^2(\partial \Omega_k) \| d\xi < \infty \). We have

\[
u_k = \mathcal{F}_{\xi \to x}^{-1}(\Delta_{O_k} - \mu^2 + \xi^2)^{-1}\hat{f}_k(\xi).
\]

Let \( \epsilon > 0 \) be less than the first positive eigenvalue of \( \Delta_{O_k} \). Then the resolvent \( (\Delta_{O_k} - \mu^2 + \xi^2)^{-1} \) is a meromorphic function of \( \xi \) in the strip \( -\epsilon < \xi < \epsilon \) having poles at \( \xi = \pm \mu \), which correspond to the zero eigenvalue and the constant eigenfunction of \( \Delta_{O_k} \). This together with the Cauchy’s integral theorem implies

\[
u_k(x, y) = v_k(x, y) + C_k e^{\text{sign}(\gamma_k) i\mu x}, \quad v_k = \mathcal{F}_{\xi \to x}^{-1}(\Delta_{O_k} - \mu^2 + (\xi + i\gamma_k)^2)^{-1}\hat{f}_k(\xi + i\gamma_k),
\]

where \( v_k \) is a unique in \( H^2(\mathbb{R} \times O_k) \) solution to the equation \((A.4)\) and \( C_k \in \mathbb{C} \) depends on \( \mu \) and \( f_k \). The term \( C_k e^{\text{sign}(\gamma_k) i\mu x} \) (resp. \( C_k e^{\text{sign}(\gamma_k) i\mu x} = C_k e^{-i\mu x} \)) appears as the residue at the pole \( \xi = \mu \) (resp. \( \xi = -\mu \)) if \( O_k \) corresponds to a right (resp. left) cylindrical end. As a consequence, for some \( c_k \in \mathbb{C} \) we have \( g_k u - c_k \varphi_k(\mu) \in D_\epsilon, \) cf. \((2.4)\). Since \( g_0 u \in D_\epsilon \), we conclude that \((2.3)\) is valid provided

\[
0 < \epsilon < \lambda = \min_{\ell \in \mathbb{N}, 1 \leq k \leq n} 4\pi^2 \ell^2 |O_k|^{-2},
\]

where \( \lambda \) is the first positive eigenvalue of the selfadjoint Laplacian on the union of \( O_1, \ldots, O_n \).

\[\Box\]

**A.2 Existence of embedded eigenvalues**

In this subsection we demonstrate that the selfadjoint Laplacian \( \Delta \) on \((\mathcal{M}, m)\) can have eigenvalues embedded into the continuous spectrum \( \sigma_c(\Delta) = [0, \infty) \). Let us construct a simple suitable example of \((\mathcal{M}, m)\).

Consider the following strip with two semi-infinite slits:

\[
\mathcal{S} = \{ x + iy \in \mathbb{C} : |x| \geq \pi, 0 < |y - \pi/2| < \pi/2 \} \cup \{ x + iy \in \mathbb{C} : -\pi < x < \pi, 0 < y < \pi \}.
\]

Let \( \Delta^D \) be the Friedrichs selfadjoint extension of the Laplacian \( -\partial_x^2 - \partial_y^2 \) initially defined on the set \( C^\infty_0(\mathcal{S} \setminus \{ -\pi + i\pi/2, \pi + i\pi/2 \}) \). It is easy to check that \( \Delta^D \) is positive and
its continuous spectrum is $[4, \infty)$.

The first eigenvalue of the Dirichlet Laplacian in the square $(-\pi/2, \pi/2) \times (0, \pi) \subset \mathbb{S}$ is 2. Extending the corresponding eigenfunction $\cos x \sin y$ to the strip $\mathbb{S}$ by zero, one obtains some function $u$ in the domain $H^1(\mathbb{S})$ of the quadratic form $q$ of $\Delta_D$. Clearly, $q[u,u] = 2$. Then the minimax principle implies that $\Delta_D$ has at least one (discrete) eigenvalue $\lambda \leq 2$ below the continuous spectrum $[4, \infty)$. We extend the corresponding eigenfunction $U$ to $\overline{\mathbb{S}} = \{ x - iy : x + iy \in \mathbb{S} \}$ by setting $U(x,y) = -U(x,y)$. Thus we constructed an eigenfunction $U$ corresponding to the (embedded) eigenvalue $\lambda \in (0, 2]$ of the Laplacian $\Delta$ on the Mandelstam diagram $(M,m)$, where $M$ is obtained from $\mathbb{S} \cup \overline{\mathbb{S}}$ by the following identifications of boundaries:

\[
\begin{align*}
\mathbb{R} + i\pi - i0 & \text{ with } \mathbb{R} - i\pi + i0; \\
\mathbb{R} + i0 & \text{ with } \mathbb{R} - i0; \\
\{ x + i\pi/2 + i0 : |x| \geq \pi \} & \text{ with } \{ x - i\pi/2 - i0 : |x| \geq \pi \}; \\
\{ x + i\pi/2 - i0 : |x| \geq \pi \} & \text{ with } \{ x - i\pi/2 + i0 : |x| \geq \pi \}.
\end{align*}
\]
