Ureaplasma spp. and Mycoplasma hominis, frequent colonizers in the lower urogenital tract, have been implicated in various infections, with antibiotic resistance growing and varying regionally. This study aims to investigate the prevalence and antibiotic resistance profiles of Ureaplasma spp. and M. hominis in outpatients in Hangzhou, China, from 2013 to 2019. A total of 135,263 outpatients were examined to determine the prevalence of Ureaplasma spp. and M. hominis, including 48,638 males and 86,625 females. Furthermore, trends in antibiotic susceptibility of Ureaplasma spp. and M. hominis during 1999–2019 were analyzed. The cultivation, identification, and antibiotic susceptibility of the bacteria (ofloxacin, ciprofloxacin, erythromycin, clarithromycin, azithromycin, josamycin, tetracycline, doxycycline, and pristinamycin) were determined using the Mycoplasma IST2 kit. Our study indicated that the overall prevalence of Ureaplasma spp. and M. hominis was 38.1% from 2013 to 2019. Ureaplasma spp. were the most frequently isolated species (overall prevalence, 31.3%), followed by Ureaplasma spp./M. hominis coinfection (6.0%) and single M. hominis infection (0.8%). The prevalence of Ureaplasma spp. and M. hominis was significantly higher in females than in males, and the highest positive rates of total Ureaplasma spp./M. hominis were observed in both female and male outpatients aged 14–20 years. During 2013–2019, josamycin, tetracycline, doxycycline, and pristinamycin maintained exceptionally high activity (overall resistance rates, <5%) against both Ureaplasma spp. and M. hominis, but ofloxacin and ciprofloxacin showed limited activity (overall resistance rates, >70%). During 1999–2019, the rates of resistance to ofloxacin and ciprofloxacin increased against both Ureaplasma spp. and M. hominis but decreased to erythromycin, clarithromycin, azithromycin, tetracycline, and doxycycline against Ureaplasma spp. In conclusion, our study demonstrates a high prevalence of Ureaplasma spp. compared to M. hominis and Ureaplasma spp./M. hominis, and their distribution was associated with sex and age. Josamycin, doxycycline, and tetracycline are promising antibiotics that have remarkable activity against Ureaplasma species and M. hominis.

KEYWORDS
Ureaplasma spp., Mycoplasma hominis, prevalence, antibiotic resistance, activity
Introduction

Ureaplasma species and Mycoplasma hominis, members of the class Mollicutes, are the smallest self-replicating and free-living organisms known, and are routinely identified as common commensal bacteria in the lower urogenital tract of healthy individuals. They are, however, sometimes implicated in various types of infections, such as chorioamnionitis, infertility, adverse pregnancy outcomes, and neonatal diseases (Waites et al., 2005; Taylor-Robinson and Lamont, 2011; Huang et al., 2015; Kletzel et al., 2018). Genital mycoplasmas can be identified in cervicovaginal and urethral specimens of 40–80% healthy humans. But they are relatively common in the urogenital tracts of sexually active adults with clinical manifestations, where Ureaplasma spp. and M. hominis can be found, with Ureaplasma spp. being the most prevalent (Song et al., 2014; Kasprzykowska et al., 2018; Beeton and Jones, 2019; Piscopo et al., 2020; Doroftei et al., 2021).

Both Ureaplasma spp. and M. hominis lack cell wall; thus, antibiotic therapies are restricted to those that prevent DNA replication (e.g., fluoroquinolones) and protein synthesis (e.g., macrolides and tetracyclines). The prevalence and antibiotic susceptibility profiles vary geographically, depending on antibiotic use and history of previous antibiotic exposure. Antibiotic resistance has been increasing in recent years probably due to the inappropriate use of antibiotics, which is most likely acquired through gene mutation or the acquisition of resistance determinants (Yang et al., 2020; Chalker et al., 2021). Therefore, it is critical to monitor the change of antibiotic susceptibility regularly to provide guidelines for the treatment of Ureaplasma spp. and M. hominis infections. The objective of this study was to determine the prevalence and antibiotic susceptibility of Ureaplasma spp. and M. hominis in outpatients in Hangzhou, China, from 2013 to 2019.

Materials and methods

Study participants

During the period of January 2013 to December 2019, a total of 135,263 outpatients were examined in the clinical laboratory at Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, China. Of these, 48,638 were males aged 14–89 years, and 86,625 were females aged 14–94 years. Furthermore, 804 Ureaplasma spp. isolates were collected from outpatients between March and June of 1999–2004, and 1,278 isolates were obtained from outpatients with genital manifestations, such as vaginal or cervical discharge, painful or burning urination, dysuria, frequent urination, and other symptoms, between January 2005 and December 2012, to determine the trend in the antibiotic susceptibility of Ureaplasma spp. (Xie and Zhang, 2006; Song et al., 2014). Additionally, 267 M. hominis isolates recovered from outpatients between January 2005 and December 2012 were included to determine the trend in the antibiotic susceptibility of M. hominis (Kong et al., 2016).

Sample collection, culture, and antibiotic susceptibility testing

Urethral specimens of male patients were obtained by inserting Dacron swabs 2–3 cm into the urethra and spinning for 5 s, and cervicovaginal specimens of female patients were obtained from the cervical area after exocervical mucus was cleansed with a swab. A commercial Mycoplasma IST2 assay (bioMérieux, Marcy-l’Etoile, tole, France) was used for the identification, semi-quantification of the concentration, and antibiotic susceptibility testing of Ureaplasma spp. and M. hominis. The specimens were inoculated and incubated according to the manufacturer’s instructions. Briefly, urethral and cervical swabs were inoculated in R1 medium, and the mixture was added to R2 medium and vortexed until the pellet dissolved. Then, the rehydrated R2 growth medium was distributed into wells on the Mycoplasma IST2 strip and protected from drying with mineral oil. The strip and the remaining broth were incubated at 37°C for 48 h and color changes were recorded at 24 h for Ureaplasma spp. and 48 h for M. hominis. Positive results were noticed when the color of the broth changed from yellow to red with an estimated density of each organism ≥10³ CFU.

Antibiotic susceptibility testing was performed for the following antibiotics: ofloxacin, ciprofloxacin, erythromycin, clarithromycin, azithromycin, josamycin, tetracycline, doxycycline, and pristinamycin. The antibiotic resistance breakpoints for the above nine antibiotics (mg/L) were as follows: ofloxacin, resistant (R) ≥4; ciprofloxacin, R ≥2; erythromycin, R ≥4; clarithromycin, R ≥4; azithromycin, R ≥4; josamycin, R ≥8; tetracycline, R ≥8; doxycycline, R ≥8; and pristinamycin, R ≥2 (Kenny and Cartwright, 2001).

Statistical analysis

The SPSS Statistics for Windows v.21.0 was used to analyze the prevalence and occurrence of resistance to the nine antibiotics tested based on the Chi-square test and Fisher’s exact test. p-values of <0.05 were considered significant statistically.

Results

Prevalence of Ureaplasma spp. and Mycoplasma hominis from 2013 to 2019

Among the 135,263 specimens tested, the overall positive rate of total Ureaplasma spp./M. hominis was 38.1% (51,504 out of 135,263). Ureaplasma spp. infection was more common than Ureaplasma spp./M. hominis coinfection (31.3% vs. 6.0%,
p < 0.001) and M. hominis infection (31.3% vs. 0.8%, p < 0.001). Of the 48,638 specimens obtained from male outpatients, 12,266 (25.2%) were positive for Ureaplasma spp., 216 (0.4%) for M. hominis, and 1970 (4.1%) for both Ureaplasma spp. and M. hominis. Females had a significantly higher prevalence of Ureaplasma spp. and M. hominis than males (p < 0.001). Of the 86,625 specimens obtained from female outpatients, 30,044 (34.7%) were positive for Ureaplasma spp., 886 (1.0%) for M. hominis, and 6,122 (7.1%) for both Ureaplasma spp. and M. hominis.

Trends in the prevalence of Ureaplasma spp. and M. hominis during the test period are shown in Figure 1. Ureaplasma spp. infection rates were ranged from 23.1 to 27.1% in males and from 32.7 to 39.9% in females, which were higher than those of M. hominis infection and Ureaplasma spp./M. hominis coinfection (M. hominis, 0.3–0.6% for males and 0.8–1.4% for females; coinfection, 3.1–5.1% for males and 5.9–8.2% for females).

Distribution of Ureaplasma spp. and Mycoplasma hominis in different age groups from 2013 to 2019

The distribution of Ureaplasma spp. and M. hominis according to the age group from 2013 to 2019 is presented in Table 1. The overall positive rate of total Ureaplasma spp./M. hominis was highest in male patients aged 14–20 years (33.6%) and lowest in male patients aged ≥51 years (25.1%), with a declining trend as age increased. Similarly, the overall positive rate of total Ureaplasma spp./M. hominis was highest in female patients aged 14–20 years (58.0%), followed by 46–50 years (54.7%), and lowest in female patients aged 50–94 years (36.7%). For Ureaplasma spp. infection, the highest positive rates were found in both male and female patients aged 14–20 years, with 28.2% for males and 40.2% for females. For M. hominis infection, the detection rate was highest in males aged 14–20 years (1.1%) and ≥51 years (0.9%), but it occurred most commonly in females aged 46–50 years (2.2%) and ≥51 years (2.2%). Notably, among the patients with Ureaplasma spp./M. hominis coinfection, the highest detection rate was found in females aged 14–20 years (16.8%) and 46–50 years (14.4%); however, close detection rates were found in males of different age groups, ranging from 3.8 to 4.9%.

Antibiotics effectiveness from 2013 to 2019

The overall resistance rates of Ureaplasma spp. and M. hominis from 2013 to 2019 are shown in Table 2. Josamycin, tetracycline, doxycycline, and pristinamycin maintained high activity against Ureaplasma spp. and M. hominis, with resistance rates all <5%. Erythromycin, clarithromycin, and azithromycin were effective against the majority of Ureaplasma spp. isolates (resistant rates, <3%). In comparison, ofloxacin and ciprofloxacin displayed
limited effectiveness against both *Ureaplasma* spp. and *M. hominis* (resistant rates, >70%).

**Antibiotic susceptibility patterns of *Ureaplasma* spp. and *Mycoplasma hominis* over 20 years**

The antibiotic susceptibility of *Ureaplasma* spp. isolates collected during 2013–2019 was compared to those collected during 1999–2004 and during 2005–2012 (Figure 2). Ofloxacin resistance of *Ureaplasma* spp. increased from 1999 (resistance rate, 24.1%) to 2019 (resistance rate, 71.9%), whereas ciprofloxacin resistance maintained high from 2001 to 2019, with resistance rates ranging from 64.2 to 93.2% (*p* < 0.001). Resistance to erythromycin, clarithromycin, and azithromycin decreased, with the exception of josamycin, which maintained extremely low (resistance rates, 0–2.8%) during the test period. Resistance to tetracycline and doxycycline increased from 1999 (tetracycline, 4.6%; doxycycline, 3.7%) to 2001 (tetracycline, 12%) or 2002 (doxycycline, 11.3%), then decreased to 2019 (tetracycline, 1.3%, *p* < 0.001; doxycycline, 0.6%, *p* < 0.001). Additionally, resistance rates to pristinamycin were low, ranging from 0 to 4.6%.

The trend in the antibiotic susceptibility of *M. hominis* isolates during 2005–2019 is shown in Figure 3. Resistance to ofloxacin and ciprofloxacin rose from 2005 (ofloxacin, 47.1%; ciprofloxacin, 41.2%) to 2019 (ofloxacin, 81.3%; ciprofloxacin, 65.4%), with peaks in 2017 for ofloxacin (87.1%, *p* < 0.001) and 2014 for ciprofloxacin (83.6%; *p* < 0.001). Resistance rates to josamycin, tetracycline, doxycycline, and pristinamycin remained low, ranging from 0 to 8.7%.

**Table 1** Distribution of *Ureaplasma* spp. and *M. hominis* in the two sexes by age from 2013 to 2019.

| Specimen | Distribution [no. (%)] | Ureaplasma spp. (n = 42,310) | *M. hominis* (n = 1,102) | Ureaplasma spp. + *M. hominis* (n = 8,092) | Total Ureaplasma spp./ *M. hominis* |

Discussion

*Ureaplasma* species and *M. hominis* are frequent colonizers in the urogenital tract of adults but are sometimes associated with a variety of diseases. This study aimed to evaluate the prevalence.
and antibiotic susceptibility of these species between 2013 and 2019. Our findings identified a high prevalence of *Ureaplasma* species and *M. hominis* (overall prevalence, 38.1%). *Ureaplasma* spp. infection was the most common (31.3%), followed by *Ureaplasma* spp./*M. hominis* coinfection (6.0%) and single *M. hominis* infection (0.8%). Compared to our previous study analyzing the period of 2005 to 2013, the positive rates of both *Ureaplasma* spp. and *M. hominis* were decreased in females but increased in males in this study (Song et al., 2014). High prevalence of genital mycoplasmas was also observed in other provinces of China. The positive rates of genital mycoplasmas were detected in 33.9% of female outpatients in Beijing, 38.7% of infertile men in Shanghai, and 47.11% of outpatients for gynecologic healthcare screening or the presence of urogenital infection symptoms in Xi’an (Wang et al., 2016; Zeng et al., 2016; Zhou et al., 2018). Similar results were reported in South Korea, Russia, and Romania (Rumyantseva et al., 2019; Lee and Yang, 2020; Doroftei et al., 2021), but relatively lower positive rates were reported in Poland, Italy, and Brazil (Ponyai et al., 2013; Foschi et al., 2018; Piscopo et al., 2020), which could be explained by the discrepancy in socioeconomic conditions, living standards, and the experimental methods used. Notably, the identification of *Ureaplasma* spp. and *M. hominis* in clinical specimens depends on a variety of commercial Mycoplasma testing kits based on molecular or culture methods, the sensitivity and specificity of which are mostly unknown. Moreover, an unequal prevalence between sexes was observed, in which the detection rates of *Ureaplasma* spp. and *M. hominis* were higher in the female population than in the male population. The higher occurrence of *Ureaplasma* spp. and *M. hominis* in females appears to be a general trend, as evidenced by an increasing number of studies (Ponyai et al., 2013; Zeng et al., 2016; Foschi et al., 2018; Kasprzykowska et al., 2018).

Our study also indicated that the prevalence of *Ureaplasma* spp. was higher in younger individuals and declined with age, but we cannot ignore the fact that the number of both male and female patients aged 14–20 years was considerably lower than that of any other age group. However, *M. hominis* was more frequently isolated from the older individuals, with an increasing trend as age increased, especially in female patients. This result is consistent with our previous study, which showed that *M. hominis* was more prevalent in male patients aged 56–60 years, and in female patients aged 61–65 years and 46–50 years (Kong et al., 2016). Lee et al. reported that *Ureaplasma* spp. were most commonly found in female patients aged 18–29 years, but *M. hominis* was more common in females aged 60–89 years, followed by 30–39 years, in Seoul, South Korea (Lee and Yang, 2020). However, Zhou et al. showed that *Ureaplasma* spp. and *M. hominis* occurred mostly in infertile men aged 26–30 years and 21–25 years, respectively, in Shanghai, China (Zhou et al., 2018). These findings suggest that *Ureaplasma* spp. are more likely to be detected in younger patients, but further studies are required to determine the association between *M. hominis* prevalence and age.
Antibiotic resistance is the leading cause of treatment failure in genital mycoplasmas infections, and the increasing antibiotic resistance has prompted researchers to conduct ongoing monitoring investigations. In this study, a significant variation in levels of sensitivity to various antibiotics was discovered. The majority of clinical *Ureaplasma* spp. isolates were susceptible to macrolides (erythromycin, clarithromycin, azithromycin, and josamycin), tetracyclines (tetracycline and doxycycline), and streptogramins (pristinamycin), suggesting that macrolides, tetracyclines, and streptogramins are effective antibiotics against *Ureaplasma* spp. However, the current findings revealed that *Ureaplasma* spp. were extremely resistant to fluoroquinolones, which is consistent with our and other recent studies on fluoroquinolone resistance in *Ureaplasma* spp. in China (Xie and Zhang, 2006; Song et al., 2014; Wang et al., 2016; Yang et al., 2020; Ma et al., 2021). In our recent study, the resistance rates of levofloxacin were 84.69% for *U. parvum* and 82.43% for *U. urealyticum*, and those of moxifloxacin were 51.44% for *U. parvum* and 62.16% for *U. urealyticum* (Yang et al., 2020). Notably, fluoroquinolone resistance levels differed significantly between countries. In Italy, 77.1% of *Ureaplasma* spp. were ciprofloxacin-resistant, and 26.3% of isolates were ofloxacin-resistant (Foschi et al., 2018). In the United States, however, the resistance rates of levofloxacin in *Ureaplasma* spp. were extremely low, with only 1.6% for *U. parvum* and 0% for *U. urealyticum* (Valentine-King and Brown, 2017). The primary variation is perhaps related to the strategy or inclination for using antibiotics in different regions.

*M. hominis* is intrinsically resistant to C14- and C15-membered macrolides (erythromycin, clarithromycin, and azithromycin), but susceptible to C16-membered macrolides (josamycin). Our results showed that the majority of clinical *M. hominis* isolates were susceptible to C16-membered macrolides (josamycin), tetracyclines (tetracycline and doxycycline), and streptogramins (pristinamycin), but most of them were resistant to fluoroquinolones (ofloxacin and ciprofloxacin). These findings were consistent with several previous studies (Wang et al., 2016; Zeng et al., 2016; Foschi et al., 2018) but differed from others (Valentine-King and Brown, 2017; Foschi et al., 2018). During the test period in China, fluoroquinolone resistance increased and reached an extraordinarily high level against both *Ureaplasma* spp. and *M. hominis*, perhaps due to the inappropriate use of fluoroquinolone agents in both poultry industry and clinical settings (Chen Z. et al., 2021; Chen H. et al., 2021).

Overall, our results showed that josamycin, tetracycline, doxycycline, and pristinamycin maintained outstanding activity against *Ureaplasma* spp. and *M. hominis*. Due to its toxicity, pristinamycin was no longer a viable alternative, so it has been unavailable for therapeutic prescription in several countries. Additionally, erythromycin, clarithromycin, and
azithromycin are all candidates for *Ureaplasma* spp. infection therapy.

This study has some important limitations. First, it was unable to discriminate between actual genital mycoplasma infection and common commensal colonization due to the lack of clinical data on the participants. Second, the Mycoplasma IST2 kit failed to separate between *Ureaplasma* spp. (*U. parvum* and *U. urealyticum*), as well as produce distinct findings for mixed cultures of *Ureaplasma* spp. and *M. hominis*, which might result in inaccurate reporting of antibiotic resistance. Third, since all clinical isolates of *Ureaplasma* spp. and *M. hominis* were generated as part of routine clinical laboratory procedures and were disposed of after being tested, the identification and antibiotic susceptibility results produced by the Mycoplasma IST2 kit cannot be compared with some other molecular-based methods or the standardized guidelines of the Clinical and Laboratory Standards Institute (CLSI) on Antimicrobial Susceptibility Testing. Regrettably, the antibiotics and breakpoints used in the Mycoplasma IST2 kit conflict with CLSI recommendations. Fourth, we were unable to perform further studies to determine the mechanisms of resistance to fluoroquinolones, macrolides, and tetracyclines in *Ureaplasma* spp. and *M. hominis*.

In conclusion, our study retrospectively analyzed the prevalence and antibiotic susceptibility of *Ureaplasma* spp. and *M. hominis* in Hangzhou, China, from 2013 to 2019. *Ureaplasma* spp. infection was relatively common, but *M. hominis* infection and *Ureaplasma* spp./*M. hominis* coinfection were exceedingly rare. Furthermore, both *Ureaplasma* spp. and *M. hominis* were more prevalent in females than in males, and their distribution was associated with age. Josamycin, doxycycline, and tetracycline are promising antibiotics with outstanding activity against *Ureaplasma* spp. and *M. hominis*.
