Abstract

We give necessary conditions for the efficient simulation of both bipartite and multipartite Hamiltonians, which are independent of the eigenvalues of Hamiltonians and based on the algebraic-geometric invariants introduced in [1] and [2]. The results show that the problem of efficient simulation of Hamiltonians on arbitrary bipartite or multipartite quantum systems cannot be described by only using eigenvalues, which is quite different to the two-qubit case.

Historically the idea of simulating Hamiltonian time evolutions was the first motivation for quantum computation [3]. Recently the ability of nonlocal Hamiltonians to simulate one another is a popular topic, which has applications in quantum control theory [4], quantum computation [5], [6], [7], [8] and the task of generating entanglement [9], [10]. The problem to parameterize the nonlocal properties of interaction Hamiltonians, so as to characterize the efficiency with which they can be used to simulate one another, is theoretically and experimentally important. There have been very active research on this problem ([11], [12],[13],[14],[15],[16],[17]). For the general treatments of this topic, we refer to [11] as the main reference.

In [11] it was shown that the efficiency with which Hamiltonian $H$, together with local operations, simulates another Hamiltonian $H'$ can be used as a criterion to endow the set of Hamiltonians with a partial order structure, that allows to compare the nonlocal capabilities of $H$ and $H'$. For two-qubit Hamiltonians, it was shown that the problem of simulation of Hamiltonians can be reduced
to the case of so-called normal forms of these Hamiltonians (Theorem in section V A of [11]). For these Hamiltonians in their normal forms, a beautiful necessary and sufficient condition about the simulating capability in terms of the majorization of eigenvalues of these Hamiltonians was given. This indicated that the partial order structure endowed on the two-qubit Hamiltonians is in close analogy to the partial ordering of bipartite pure states endowed by their capabilities to be converted by LOCC ([18]).

It is natural to consider the simulation problem of Hamiltonians on arbitrary bipartite quantum systems. We can imagine that in higher dimensions, Hamiltonians have more nonlocal degrees of freedom than the two qubit case, and there is no result about ”normal forms” of Hamiltonians on arbitrary bipartite quantum systems, this may make the problem more difficult and it seems hopeless to give a characterization based only on the majorization of some numerical quantities (as in Theorem of section F of [11]). In [19] it is proved that $m^2n^2 - m^2 - n^2 + 1$ nonlocal parameters are needed to describe the set of equivalent classes of bipartite mixed states on $H_A^m \otimes H_B^n$ under local unitary operations. A similar parameter counting argument as [19] shows that there must be at least $m^2n^2 - 2(m^2 + n^2) + 3$ nonlocal parameters for the equivalent classes of bipartite Hamiltonians on $H_A^m \otimes H_B^n$ under local unitary operations. When we consider the ability of nonlocal Hamiltonians to simulate one another with the help of local unitary operations, it is natural to imagine that these continuous invariants of Hamiltonians under local unitary operations may give constraints on these Hamiltonians $H$ and $H'$ if there is a simulation relation using local unitary operations between them, and any such constraint must be expressed by these invariants. In our previous works [1] and [2] the algebraic-geometric invariants of bipartite mixed states (i.e. semi-positive self-adjoint operators) were introduced as their nonlocal invariants (i.e., these algebraic sets are kept invariant under local unitary operations). These algebraic-geometric invariants depends only on eigenvectors and are independent of eigenvalues of the semi-positive adjoint operators. We can think these algebraic-geometric invariants as nonlocal invariants of semi-positive bipartite Hamiltonians and ask if there exists any constraint on these invariants of two semi-positive Hamiltonians $H$ and $H'$ if $H$ can be simulated by $H'$ using local unitary operations.

In this paper, we show that the efficient simulation relation between two semi-positive bipartite Hamiltonians of the same rank implies the equalities of these algebraic-geometric invariants of them. This necessary condition is also extended to the efficient simulation of multipartite Hamiltonians. Since these algebraic-geometric invariants are independent of the eigenvalues and only measure the position of eigenvectors of the Hamiltonians. Thus our results strongly suggest that the eigenvectors play a more fundamental role in the efficient simulation problem of Hamiltonians on arbitrary bipartite or multipartite systems. This is quite different to the two qubit case studied in [11].
In this paper, we say, for two bipartite Hamiltonians \( H \) and \( H' \) on \( H_A^m \otimes H_B^n \), \( H' \) can be efficiently simulated by \( H \) with local unitary operations, write as \( H' \prec_{LU} H \), if \( H' \) can be written as a convex combination of conjugates of \( H \) by local unitary operations, \( H' = p_1(U_1 \otimes V_1)H(U_1 \otimes V_1)^\dagger + ... + p_s(U_s \otimes V_s)H(U_s \otimes V_s)^\dagger \), where \( p_1, ..., p_s \) are positive real numbers such that \( p_1 + ... + p_s = 1 \), \( U_1, ..., U_s \) and \( V_1, ..., V_s \) are unitary operations on \( H_A^m \) and \( H_B^n \) respectively. Here we use \( \dagger \) for the adjoint. This is equivalent to the notion "infinitesimal simulation" in [11] and "first order simulation in [16]. In [11] and [16] it is shown without neglecting the local terms.

If \( H' \prec_{LU} H \), where \( H \) is a semi-positive self-adjoint operator, it is clear that \( H' \) has to be a semi-positive self-adjoint operator and \( tr(H') = tr(H) \). Thus it is clear that \( H' \prec_{LU} H \) is equivalent to \( H' - \frac{tr(H')}{mn} I_{mn} \prec_{LU} H - \frac{tr(H)}{mn} I_{mn} \), so we do not restrict to the traceless Hamiltonians in this paper.

We have the following observation. First we recall the following result in [20].

**Lemma 1.** Let \( T = \sum p_i |v_i\rangle\langle v_i| \), where \( p_i \)'s are positive real numbers, be a positive self-adjoint operator on a finite dimensional Hilbert space. Then the range \( range(T) \) of \( T \) is the linear span of vectors \( v_i \)'s.

If \( H = |v\rangle\langle v| \) and \( H' = |v'\rangle\langle v'| \) where \( |v\rangle \) and \( |v'\rangle \) are pure states and \( H' \) can be simulated by \( H \) efficiently, i.e., \( H' \prec_{LU} H \), actually the Schmidt ranks of \( |v\rangle \) and \( |v'\rangle \) have to be the same. In fact, if there exist positive numbers \( p_1, ..., p_s \) and local unitary operations \( U_1 \otimes V_1, ..., U_s \otimes V_s \) such that, \( \sum p_i U_i \otimes V_i H(U_i \otimes V_i)^\dagger = H' \), it is clear that \( U_i \otimes V_i H(U_i \otimes V_i)^\dagger = |(U_i \otimes V_i)v\rangle\langle(U_i \otimes V_i)v| \), and from Lemma 1, \( |(U_i \otimes V_i)v\rangle \) is in the range of \( H' \). Hence \( |v'\rangle = |(U_i \otimes V_i)v\rangle \) and the Schmidt ranks of \( |v\rangle \) and \( |v'\rangle \) have to be the same.

For semi-positive bipartite Hamiltonians (equivalently, bipartite mixed states, i.e., semi-positive self-adjoint operators) on \( H_A^m \otimes H_B^n \), algebraic sets \( V_A^k(H) \) in \( CP^{n-1} \) (respectively \( V_B^k(H) \) in \( CP^{n-1} \) ) are introduced in [1] as the *degenerating locus* of the measurement of them by separable pure states. For any given semi-positive self-adjoint operator (bipartite mixed states or semi-positive Hamiltonians) \( \rho \) on \( H_A^m \otimes H_B^n \), we consider the expression \( \langle \phi_1 \otimes \phi_2 | \rho | \phi_1 \otimes \phi_2 \rangle \) for any pure states \( \phi_1 \in H_A^m \) and \( \phi_2 \in H_B^n \). For any fixed \( \phi_1 \in P(H_A^m) \), where \( P(H_A^m) \) is the projective space of all pure states in \( H_A^m \), \( \langle \phi_1 \otimes \phi_2 | \rho | \phi_1 \otimes \phi_2 \rangle \) is a Hermitian bilinear form on \( H_B^n \), denoted by \( \langle \phi_1 | \rho | \phi_1 \rangle \). We consider the *degenerating locus* of this bilinear form, i.e., \( V_A^k(\rho) = \{ \phi_1 \in P(H_A^m) : rank(\langle \phi_1 | \rho | \phi_1 \rangle) \leq k \} \).
for \( k = 0, 1, \ldots, n - 1 \). We can use the coordinate form of this formalism. Let 
\( \{|11\rangle, \ldots, |1n\rangle, \ldots, |m1\rangle, \ldots, |mn\rangle \} \) be the standard orthogonal basis of \( H^2_A \otimes H^2_B \) and \( \rho \) be an arbitrary (semi)positive self-adjoint operator. We represent the 
matrix of \( \rho \) in the basis \( \{|11\rangle, \ldots, |1n\rangle, \ldots, |m1\rangle, \ldots, |mn\rangle \} \), and consider \( \rho \) as a 
blocked matrix \( \rho = (\rho_{ij})_{1 \leq i \leq m, 1 \leq j \leq m} \) with each block \( \rho_{ij} \) a \( n \times n \) matrix corresponding to the \( |i1\rangle, \ldots, |in\rangle \) rows and the \( |j1\rangle, \ldots, |jn\rangle \) columns. For any pure 
state \( \phi_i = r_1|1\rangle + \ldots + r_m|m\rangle \in P(H^m_n) \) the matrix of the Hermitian linear form 
\( \langle \phi_1 | \rho | \phi_1 \rangle \) with the basis \( |1\rangle, \ldots, |n\rangle \) is \( \Sigma_{ij} r_i r_j^\dagger \rho_{ij} \). Thus the “degenerating locus” is 
actually as follows.

\[
V^k_A(\rho) = \{(r_1, \ldots, r_m) \in CP^{m-1} : \text{rank}(\Sigma_{ij} r_i r_j^\dagger \rho_{ij}) \leq k \}
\]

for \( k = 0, 1, \ldots, n - 1 \). Similarly \( V^k_B(\rho) \subseteq CP^{m-1} \) can be defined. It is known 
from Theorem 1 and 2 of [1] that these sets are algebraic sets (zero locus of 
several multi-variable polynomials, see [21]) and they are invariants under local 
unitary operations depending only on the eigenvectors of \( \rho \). Actually these algebraic 
sets can be computed ease as follows.

Let \( \{|11\rangle, \ldots, |1n\rangle, \ldots, |m1\rangle, \ldots, |mn\rangle \} \) be the standard orthogonal basis of \( H^2_A \otimes 
H^2_B \) as above and \( \rho = \Sigma_{i=1}^m p_i |v_i\rangle \langle v_i| \) be any given representation of \( \rho \) as a convex 
combination of projections with \( p_1, \ldots, p_m > 0 \) (for example, we can take the spectral 
decomposition \( \rho = \Sigma_{i=1}^m \lambda_i |\psi_i\rangle \langle \psi_i| \) as a such representation). Suppose \( v_i = 
\Sigma_{j=1}^n a_{ij} |j\rangle \), \( X = (a_{ij})_{1 \leq i \leq m, 1 \leq j \leq n} \) is the \( mn \times t \) matrix. Then it is clear 
that the matrix representation of \( \rho \) with the basis \( \{|11\rangle, \ldots, |1n\rangle, \ldots, |m1\rangle, \ldots, |mn\rangle \} \) is 
\( X P X^\dagger \), where \( P \) is the diagonal matrix with diagonal entries \( p_1, \ldots, p_t \). We 
may consider the \( mn \times t \) matrix \( X \) as a \( m \times 1 \) blocked matrix with each block \( X_w \), 
where \( w = 1, \ldots, m \), a \( n \times t \) matrix corresponding to \( \{|w1\rangle, \ldots, |wn\rangle \} \). It is clear 
\( \rho_{ij} = X_i P X_j^\dagger \) and \( \Sigma_{i,j} r_i r_j^\dagger \rho_{ij} = (\Sigma_i r_i X_i) P (\Sigma_i r_i X_i)^\dagger \). From simple linear algebra 
\( V^k_A(\rho) \) is just the set of points \( (r_1, \ldots, r_m) \in CP^{m-1} \) such that \( \text{rank}(\Sigma_i r_i X_i) \) is 
less than \( k + 1 \), i.e., \( V^k_A(\rho) \) is the algebraic set in \( CP^{m-1} \) as the zero locus of the 
determinants of all \( (k + 1) \times (k + 1) \) submatrices of \( \Sigma_i r_i X_i \) (see [1]).

We can see that \( V^k_A(\rho) \) is independent of eigenvalues \( \lambda_i \)’s if it is computed from 
the spectral decomposition \( \rho = \Sigma_{i=1}^m \lambda_i |\psi_i\rangle \langle \psi_i| \), since it is computed from the 
matrix \( X \) depending only on eigenvectors \( |\psi_i\rangle \)’s. For example, let \( T \) be a 
two-qubit mixed state with some of the following 4 Bell states as its eigenvectors.

\[
|v_1\rangle = \frac{1}{\sqrt{2}}(|11\rangle + |22\rangle)
\]

\[
|v_2\rangle = \frac{1}{\sqrt{2}}(|11\rangle - |22\rangle)
\]

\[
|v_3\rangle = \frac{1}{\sqrt{2}}(|12\rangle + |21\rangle)
\]

\[
|v_4\rangle = \frac{1}{\sqrt{2}}(|12\rangle - |21\rangle)
\]
It is easy to calculate the matrix \( r_1X_1 + r_2X_2 \) of the whole 4 Bell states, it is the following 2 × 4 matrix.

\[
\begin{pmatrix}
  r_1 & r_1 & r_2 & -r_2 \\
  r_2 & -r_2 & r_1 & r_1
\end{pmatrix}
\]

Therefore \( V_A^0(T) \) and \( V_A^1(T) \) can be computed from the submatrix consisting of \( \text{rank}(T) \) columns of the above matrix. Thus \( V_A^0(T) \) is always empty, \( V_A^1(T) \) is the set of 2 points when \( \text{rank}(T) = 2 \) and empty when \( \text{rank}(T) = 3, 4. \)

From [1], Schmidt ranks of pure states \( \rho \) (ie, projection operator to a unit vector) are just the codimensions of the algebraic sets \( \text{codim}V_A^0(\rho) = \text{codim}V_B^0(\rho) \). Therefore it is natural to think the above observation can be extended to the equalities of these algebraic sets of arbitrary bipartite semi-positive Hamiltonians of the same rank if they can be simulated efficiently. In this paper we give such a necessary condition about the efficient simulation of semi-positive Hamiltonians.

**Theorem 1.** Let \( H \) and \( H' \) be the semi-positive Hamiltonians on the bipartite quantum system \( H_A^m \otimes H_B^n \) with the same rank, ie., \( \text{dim}(\text{range}(H)) = \text{dim}(\text{range}(H')) \). Suppose that \( H' \prec_{LU} H \), that is, \( H' \) can be simulated by \( H \) efficiently by using local unitary operations. Then \( V_A^k(H) = V_A^k(H') \) for \( k = 0, ..., n - 1 \) and \( V_B^k(H) = V_B^k(H') \) for \( k = 0, ..., m - 1 \), here the equality of algebraic sets means they are isomorphic via projective linear transformations of complex projective spaces.

The following observation is the the key point of the proof of Theorem 1. From Lemma 1 in [20] as cited above, the range of \( \rho \) is the linear span of vectors \( |v_1\rangle, ..., |v_s\rangle \). We take any \( \text{dim}(\text{range}(\rho)) \) linear independent vectors in the set \( \{ |v_1\rangle, ..., |v_s\rangle \} \), say they are \( |v_1\rangle, ..., |v_s\rangle \), where \( s = \text{dim}(\text{range}(\rho)) \). Let \( X' \) be the \( mn \times s \) matrix with columns corresponding to the \( s \) vectors \( |v_1\rangle, ..., |v_s\rangle \)'s coordinates in the standard basis of \( H_A^m \otimes H_B^n \). Then \( X' \) is a submatrix of the above-described matrix \( X \) and each column of \( X \) is a linear combination of columns in \( X' \). We consider \( X' \) as \( m \times 1 \) blocked matrix with blocks \( X'_1, ..., X'_m \) (\( n \times s \) matrices) as above. It is clear that \( V_A^k(\rho) \) is just the zero locus of determinants of all \( (k + 1) \times (k + 1) \) submatrices of \( \Sigma r_iX'_i \), since any column in \( \Sigma r_iX_i \) is a linear combination of columns in \( \Sigma r_iX'_i \) (thus \( \text{rank}(\Sigma r_iX'_i) \leq k \) is equivalent to \( \text{rank}(\Sigma r_iX_i) \leq k \)).

**Proof of Theorem 1.** Suppose \( H' \prec_{LU} H \), then there exist positive numbers \( p_1, ..., p_s \) and local unitary operations \( U_1 \otimes V_1, ..., U_t \otimes V_t \), such that, \( \Sigma_{i=1}^t p_iU_i \otimes V_i H(U_i \otimes V_i)^\dagger = H' \). Let \( H = \Sigma_{i=1}^s q_i|\psi_i\rangle\langle\psi_i| \), where \( s = \text{dim}(\text{range}(H)) \), \( q_1, ..., q_s \) are eigenvalues of \( H \) and \( |\psi_1\rangle, ..., |\psi_s\rangle \) are eigenvectors of \( H \). Then
it is clear that \((U_i \otimes V_i)H(U_i \otimes V_i)\) and thus \(H' = \sum_{i=1}^{s} p_i q_i [(U_i \otimes V_i)\psi_i]\). This is a representation of \(H\) as a convex combination of projections. From Lemma 1 \(\text{range}(H')\) is the linear span of \([|U_1 \otimes V_1\rangle\psi_1|,\ldots,|U_1 \otimes V_1\rangle\psi_s]\), since they are \(\text{dim} \text{range}(H') = s\) linear independent vectors in \(\text{range}(H')\). From our above observation \(V_A^k(H')\) can be computed from the matrix \(X'\) of vectors \([|U_1 \otimes V_1\rangle\psi_1|,\ldots,|U_1 \otimes V_1\rangle\psi_s]\) and thus \(V_A^k(H') = V_A^k((U_1 \otimes V_1)H(U_1 \otimes V_1)^\dagger)\) from the definition. Thus the conclusion follows from Theorem 1 in [1].

Since the algebraic-geometric invariants are independent of eigenvalues, thus our above theorem is a necessary condition of simulation of Hamiltonians without referring to eigenvalues. As described in e.g. [11] and [16], local terms like \(I \otimes K_B\) and \(K_A \otimes I\) are considered irrelevant to the simulation process up to the second order, this leads to the so-called normal forms of two-qubit Hamiltonians. We can recall the Theorem in section F of [11], for Hamiltonians \(H\) and \(H'\) in their normal forms, i.e., \(H = \Sigma_i h_i \sigma_i \otimes \sigma_i\) and \(H' = \Sigma_i h'_i \sigma_i \otimes \sigma_i\), where \(\sigma_i\)'s are Pauli matrices, on two-qubit systems, \(H' \prec simply \(h\) and \(h'\) can be determined from the eigenvalues of Hamiltonians \(H\) and \(H'\) uniquely. However Theorem 1 implies that in the case of arbitrary bipartite quantum systems, the algebraic-geometric invariants which are independent of eigenvalues play a more fundamental role. This is also illustrated in the following example of efficient simulation of Hamiltonians in \(H_A^3 \otimes H_B^3\).

Example 1. Let \(|v_1\rangle, |v_2\rangle, |v_3\rangle\) be the following 3 unit vectors in \(H_A^3 \otimes H_B^3\).

\[
|v_1\rangle = \frac{1}{3} (e^{i\eta_1}|11\rangle + |22\rangle + |33\rangle)
\]
\[
|v_2\rangle = \frac{1}{3} (e^{i\eta_2}|12\rangle + |23\rangle + |31\rangle)
\]
\[
|v_3\rangle = \frac{1}{3} (e^{i\eta_3}|13\rangle + |21\rangle + |32\rangle)
\]

where \(\eta_1, \eta_2, \eta_3\) are 3 real parameters. Let \(H_{\eta_1, \eta_2, \eta_3} = (|v_1\rangle\langle v_1| + |v_2\rangle\langle v_2| + |v_3\rangle\langle v_3|\). This is a continuous family of Hamiltonians in \(H_{\eta_1, \eta_2, \eta_3}\) of rank 3 parameterized by three real parameters.

It is easy to calculate that \(V_A^2(H_{\eta_1, \eta_2, \eta_3})\) is just the elliptic curve (see [21],[22]) in \(CP^2\) defined by \(r_1^3 + r_2^3 + r_3^3 - \frac{e^{i\eta_1} + e^{i\eta_2} + e^{i\eta_3}}{r_1 + r_2 + r_3} r_1 r_2 r_3 = 0\). Set \(g(\eta_1, \eta_2, \eta_3) = \frac{e^{i\eta_1} + e^{i\eta_2} + e^{i\eta_3}}{r_1 + r_2 + r_3}\) and \(k(x) = \frac{r_3^2 (r_1^2 + r_2^2)}{r_1^2 + r_2^2 + r_3^2}\), then \(k(g(\eta_1, \eta_2, \eta_3))\) is the moduli function of elliptic curves. From algebra-geometry it is known that if \(k(g(\eta_1, \eta_2, \eta_3)) \neq 0, 27, -216\), then \(V_A^2(H_{\eta_1, \eta_2, \eta_3})\) is not the union of 3 lines and when \(k(g(\eta_1, \eta_2, \eta_3)) = 0\) or \(27\) or \(-216\), \(V_A^2(H_{\eta_1, \eta_2, \eta_3})\) is the union of 3 lines. Moreover \(V_A^2(H_{\eta_1, \eta_2, \eta_3})\) is
isomorphic to $V^2_A(H_{\eta_1', \eta_2', \eta_3'})$ by projective linear transformations if and only if $k(g(\eta_1, \eta_2, \eta_3)) = k(g(\eta_1', \eta_2', \eta_3'))$ (see section 7.2, pp.363-396 of [22]). Thus we immediately know that $H_{0,0,0}$ cannot be efficiently simulated by $H_{0,0,0}$ using local unitary operations from Theorem 1. Generally we have the following result.

**Corollary 1.** $H_{\eta_1', \eta_2', \eta_3'}$ cannot be simulated by $H_{\eta_1, \eta_2, \eta_3}$ efficiently by using local unitary transformations, i.e., we cannot have $H_{\eta_1', \eta_2', \eta_3'} \prec_{\text{LU}} H_{\eta_1, \eta_2, \eta_3}$, if $k(g(\eta_1, \eta_2, \eta_3)) \neq k(g(\eta_1', \eta_2', \eta_3'))$, though the 3 nonzero eigenvalues of $H_{\eta_1, \eta_2, \eta_3}$, $H_{\eta_1', \eta_2', \eta_3'}$ and their partial traces are all 1.

**Proof.** It is easy to calculate the eigenvalues to check the 2nd conclusion. The first conclusion is from Theorem 1 and the above-described well-known fact about elliptic curves.

This example strongly suggests that the problem of efficient simulation of Hamiltonians on arbitrary bipartite quantum systems is quite different to the problem in two-qubit case as studied in [11].

Let $S$ be the swap operator on the bipartite system $H^n_A \otimes H^n_B$ defined by $S|ij\rangle = |ji\rangle$. For any Hamiltonian $H$, $S(H) = SHS^\dagger$ corresponds to the Hamiltonian evolution of $H$ with $A$ and $B$ interchanged. It is very interesting to consider the problem if $H$ can be simulated by $S(H)$ efficiently. This led to some important consequences in the discussion VII of [11]. For example it was shown there are examples that $H$ and $S(H)$ cannot be simulated efficiently with one another in higher dimensions. Thus in higher dimensions nonlocal degrees of freedom of Hamiltonians cannot be characterized by quantities that are symmetric with respect to $A$ and $B$, such as eigenvalues. This conclusion is also obtained from the above Corollary 1. From Theorem 1 we have the following necessary condition about $H \prec_{\text{LU}} S(H)$.

**Corollary 2.** Let $H$ be a semi-positive Hamiltonian on $H^n_A \otimes H^n_B$. Suppose $H \prec_{\text{LU}} S(H)$. Then $V^k_A(H) = V^k_B(H)$ for $k = 0, ..., n - 1$.

The following is a Hamiltonian $H$ on $3 \times 3$ system for which $H$ cannot be simulated efficiently by $S(H)$.

**Example 2.** $H = |\phi_1\rangle\langle\phi_1| + |\phi_2\rangle\langle\phi_2| + |\phi_3\rangle\langle\phi_3|$, where,

$$ |\phi_1\rangle = \frac{1}{\sqrt{3}}(|11\rangle + |21\rangle + |32\rangle) $$

$$ |\phi_2\rangle = \frac{1}{\sqrt{1+|v|^2}}(|12\rangle + v|22\rangle) \quad (2) $$

$$ |\phi_3\rangle = \frac{1}{\sqrt{1+|\lambda|^2}}(|13\rangle + \lambda|23\rangle) $$
Then it is easy to compute that $V^2_a(H)$ is the sum of 3 lines in $CP^2$ defined by $r_1 + r_2 = 0, r_1 + vr_2 = 0$ and $r_1 + \lambda r_2 = 0$ for $v \neq \lambda$ and both $v, \lambda$ are not 1, and $V^2_b(H)$ is the sum of 2 lines in $CP^2$ defined by $r_2 = 0$ and $r_3 = 0$. Thus we cannot have $H \preceq_{LU} S(H)$.

The following example shows that our results can lead to non-trivial constraints without referring to eigenvalues even in the two-qubit case if local terms are not neglected (as in our definition). Although local terms may be physically irrelevant in the setting of [11] and [16], Example 3 below illustrates mathematically how our results work.

Example 3. Let $H = \lambda_1|\psi_1\rangle\langle\psi_1| + \lambda_2|\psi_2\rangle\langle\psi_2|$ and $H' = \lambda'_1|\psi'_1\rangle\langle\psi'_1| + \lambda'_2|\psi'_2\rangle\langle\psi'_2|$ be two Hamiltonians on $H^2_A \otimes H^2_B$, where $\lambda$’s are any given positive real numbers such that $trH = trH'$ and

\[
|\psi_1\rangle = \frac{1}{\sqrt{2}}(|11\rangle + |22\rangle) \\
|\psi_2\rangle = \frac{1}{\sqrt{2}}(|11\rangle - |22\rangle) \\
|\psi'_1\rangle = \frac{1}{\sqrt{2}}(|11\rangle + |22\rangle) \\
|\psi'_2\rangle = |12\rangle
\]

Then we know $H$ and $H'$ are two rank 2 Hamiltonians. It is easy to compute that $V^1_a(H)$ is the algebraic set of two points $(1 : 0)$ and $(0 : 1)$ in $CP^1$ and $V^1_a(H')$ is the algebraic set of one point $(0 : 1)$ in $CP^1$. Hence we cannot have $H' \preceq_{LU} H$ from the Theorem 1.

We can now observe the compatibility of our necessary condition Theorem 1 with the sufficient and necessary condition in two-qubit case in [11]. For two two-qubit Hamiltonians $H$ and $H'$ in their normal forms, i.e., $H = \Sigma_i h_i \sigma_i \otimes \sigma_i$ and $H' = \Sigma_i h'_i \sigma_i \otimes \sigma_i$, it is proved in [11] that $H' \preceq_{LU} H$ if and only if $h' = (h'_1, h'_2, h'_3) \prec_s h = (h_1, h_2, h_3)$, i.e., $h'$ is s-majorized by $h$. It is clear that the 4 eigenvectors of any two-qubit Hamiltonian in its normal form are exactly 4 Bell states. Thus if $H = \Sigma_i h_i \sigma_i \otimes \sigma_i$ is of the form $T - \frac{4T}{4} I_4$, where $T$ is a semi-positive two-qubit Hamiltonian, then the algebraic-geometric invariants of $T$ are fixed, i.e., $V^0_A(T)$ is empty, and $V^1_A(T)$ is the set of 2 points when $rank(T) = 2$ and empty when $rank(T) = 3$ or 4. Thus we can see that our necessary condition Theorem 1 is void when applied to two-qubit Hamiltonians in their normal forms, the necessary condition in this paper is compatible with the main result in [11].

Actually the algebraic geometric invariants in [1] can be used to give more necessary conditions for the efficient simulation of Hamiltonians by using local unitary operations.
Theorem 2. Let $H$ and $H'$ be two semi-positive Hamiltonians on $H_A^m \otimes H_B^n$. Suppose that there exists a representation of $H$ as a convex combination $H = \sum_i q_i |v_i\rangle\langle v_i|$, with positive $q_i$’s and the Schmidt rank of $|v_1\rangle$ is $\min\{m,n\}$. Moreover $V_A^0(H')$ is not empty. Then $H'$ cannot be simulated by $H$ efficiently by using local unitary operations, i.e., we cannot have $H' \prec_{LU} H$.

Proof. From the condition, there exist positive $p_1,\ldots,p_t$ and local unitary operations $U_1 \otimes V_1,\ldots,U_t \otimes V_t$, such that, $\Sigma_{i=1}^t p_i U_i \otimes V_i H(U_i \otimes V_i) = H'$. It is clear that $(U_i \otimes V_i)H(U_i \otimes V_i) = \Sigma_{j=1}^s |q_j\rangle\langle q_j|(U_i \otimes V_i)v_j$, and thus $H' = \Sigma_{i,j}^t p_i q_j |(U_i \otimes V_i)v_j\rangle\langle(U_i \otimes V_i)v_j|$. From Lemma 1 in [20] as cited (Lemma 1), $\text{range}(H')$ is the linear span of vectors $(U_1 \otimes V_1)v_j$ for $i = 1,\ldots,t$ and $j = 1,\ldots,s$. From the above description about the computation of $V_A^0(H')$, we can compute it by choosing $\text{dim}(\text{range}(H'))$ linear independent vectors in this set $\{(U_1 \otimes V_1)v_1,\ldots,(U_1 \otimes V_1)v_s,\ldots,(U_1 \otimes V_1)v_1,\ldots,(U_1 \otimes V_1)v_s\}$. Therefore we can choose one of these $\text{dim}(\text{range}(H'))$ linear independent vectors to be $(U_1 \otimes V_1)v_1$, whose Schmidt rank is $\min\{m,n\}$. From [1] and the definition, we know that $V_A^0(H')$ has to be the empty set. This is a contradiction and the conclusion is proved.

Example 4. Let $H = |v\rangle\langle v|$ and $H' = \frac{1}{2}(|u_1\rangle\langle u_1| + |u_2\rangle\langle u_2|)$ be two Hamiltonians on $H_A^1 \otimes H_B^3$ where

$$|v\rangle = \frac{1}{\sqrt{3}}(|11\rangle + |22\rangle + |33\rangle)$$

$$|u_1\rangle = \frac{1}{\sqrt{2}}(|11\rangle + |22\rangle)$$

$$|u_2\rangle = \frac{1}{\sqrt{2}}(|11\rangle - |22\rangle)$$

It is clear that $V_A^0(H')$ is the set of one point $(0 : 0 : 1)$ in $CP^3$, thus nonempty. On the other hand $H$ satisfies the condition in Theorem 2. Thus we cannot have $H' \prec_{LU} H$.

For multipartite Hamiltonians on $H_{A_1}^{m_1} \otimes \cdots \otimes H_{A_n}^{m_n}$, the definition $H' \prec_{LU} H$ can be naturally extended as follows. We say that multipartite Hamiltonian $H'$ can be simulated by $H$ efficiently using local unitary operations, written as $H' \prec_{LU} H$, if there are positive real numbers $p_1,\ldots,p_s$ such that $p_1 + \cdots + p_s = 1$ and unitary operations $U_1^{m_1},\ldots,U_s^{m_s}$ on $H_{A_1}^{m_1},\ldots,H_{A_n}^{m_n}$ respectively, such that, $H' = p_1(U_1^{m_1} \otimes \cdots \otimes U_s^{m_s})H(U_1^{m_1} \otimes \cdots \otimes U_s^{m_s})^\dagger + \cdots + p_s(U_s^{m_s} \otimes \cdots \otimes U_s^{m_s})H(U_s^{m_s} \otimes \cdots \otimes U_s^{m_s})^\dagger$. Then we can use the algebraic-geometric invariants in [2] to give the following necessary condition.

Theorem 3. Let $H$ and $H'$ be the semi-positive Hamiltonians on the multipartite quantum system $H_{A_1}^{m_1} \otimes \cdots \otimes H_{A_n}^{m_n}$ with the same rank. Suppose that $H' \prec_{LU} H$, that is, $H'$ can be simulated by $H$ efficiently by using local unitary
operations. Then $V_{A_1,\ldots,A_n}^k(H) = V_{A_1,\ldots,A_n}^k(H')$ for any possible $k$ and any possible $A_{i_1},\ldots,A_{i_j}$, here the equality of algebraic sets means they are isomorphic via projective linear transformations of the product of complex projective spaces.

The proof is the same as the proof of Theorem 1.

The following example is 3 qubit case.

**Example 5.** Let $H$ and $H'$ be rank 4 Hamiltonians on $H_2^A \otimes H_2^B \otimes H_2^C$, $H = |\phi_1\rangle\langle \phi_1| + |\phi_2\rangle\langle \phi_2| + |\phi_3\rangle\langle \phi_3| + |\phi_4\rangle\langle \phi_4|$ and $H' = |\phi'_1\rangle\langle \phi'_1| + |\phi'_2\rangle\langle \phi'_2| + |\phi'_3\rangle\langle \phi'_3| + |\phi'_4\rangle\langle \phi'_4|$, where,

\[
|\phi_1\rangle = \frac{1}{\sqrt{2}}(|010\rangle - |011\rangle) \\
|\phi_2\rangle = \frac{1}{\sqrt{2}}(|100\rangle - |110\rangle) \\
|\phi_3\rangle = \frac{1}{\sqrt{2}}(|001\rangle - |101\rangle) \\
|\phi_4\rangle = \frac{1}{\sqrt{2}}(|000\rangle - |111\rangle) \\
|\phi'_1\rangle = \frac{1}{\sqrt{2}}(|000\rangle - |010\rangle) \\
|\phi'_2\rangle = \frac{1}{\sqrt{2}}(|011\rangle - |010\rangle) \\
|\phi'_3\rangle = \frac{1}{\sqrt{2}}(|010\rangle - |110\rangle) \\
|\phi'_4\rangle = \frac{1}{\sqrt{2}}(|011\rangle - |111\rangle)
\]

Then we can compute that $V_{A:B}^1(H)$ is the sum of $CP^1 \times (1:0), (0:1) \times CP^1$ and $(1:0) \times (0:1)$ in $CP^1 \times CP^1$, and $V_{A:B}^1(H')$ is the set of two points $(1:1) \times (0:1)$ and $(1:1) \times (0:1)$ in $CP^1 \times CP^1$. Thus from Theorem 3, we cannot have $H' \prec_{LU} H$.

In conclusion, we have proved necessary conditions for the efficient simulation of both bipartite and multipartite Hamiltonians using local unitary operations, which are independent of eigenvalues and based on algebraic-geometric invariants. These conditions indicated that the in higher dimension bipartite cases or multipartite cases, the relation of efficient simulation of Hamiltonians depends more on the eigenvectors than eigenvalues. This is quite different to the two-qubit case studied in [11].

It is natural to ask if the techniques from algebraic geometry used here can be extended to find not only necessary but also sufficient conditions of simulating semi-positive bipartite Hamiltonians by another with local unitary operations. For low rank semi-positive bipartite Hamiltonians or semi-positive Hamiltonians on low dimensional bipartite systems, it seems that the eigenvalues of these Hamiltonians, eigenvalues of their partial traces and algebraic-geometric invariants are near a complete set of invariants under local unitary operations, i.e., we
almost can determine exactly in which equivalent class the bipartite Hamiltonians are if we know all these invariants. Thus in these cases it seems hopeful to extend the techniques here to find necessary and sufficient conditions of simulation problem of Hamiltonians. However in general case we think it would be difficult to get necessary and sufficient conditions about this problem based on present-known invariants. We speculate that more invariants of bipartite Hamiltonians under local unitary operations have to be found for the purpose to completely describe the ability of bipartite Hamiltonians to simulate one an-
other with the help of local unitary operations.
