Abstract

A new Schiff base receptor (3) was synthesized by an equimolar reaction between the isonicotinic hydrazide and 2,4-dihydroxybenzaldehyde in ethanol. Receptor 3 based demonstrated excellent selectivity and sensitivity towards Cu\(^{2+}\) ions and Al\(^{3+}\) ions by UV–vis absorption spectroscopy and fluorescence spectroscopy, respectively. Receptor 3 showed a detectable color change from colorless to yellow with a red-shift (\(\Delta \lambda \approx 70\) nm) in the absorption spectra in the presence of Cu\(^{2+}\). In the emission study of 3, Al\(^{3+}\) showed a significant fluorescent enhancement (\(\lambda_{\text{em}} = 473\) nm) over a wide range of tested metal ions. The quantum yield of receptor 3 (\(\phi = 0.0021\)) increases \(\sim 230\) folds in the presence of Al\(^{3+}\) ions to form receptor 3.Al\(^{3+}\) complex (\(\phi = 0.484\)). Receptor 3 showed high selectivity for Al\(^{3+}\) with a \(K_a\) of \(4.8 \times 10^4\) M\(^{-1}\) and LOD of 3.0 nM. In comparison, the \(K_a\) for Cu\(^{2+}\) was \(1.3 \times 10^4\) M\(^{-1}\) and LOD of 1.9 \(\mu\)M. Receptor 3 is an excellent chemosensor for detecting Al\(^{3+}\) ions indicated by its nanomolar range LOD. The quick response, easy-synthesis, and high sensitivity make receptor 3 an ideal sensor for detecting Al\(^{3+}\) ions in a semi-aqueous medium and living cells.
1. Introduction

The Development of highly specific and sensitive chemosensors has attracted significant interest in detecting bioactive metal ions and toxic metal ions due to their importance in chemical, biological, medical, material, and environmental sciences.[1,2,3,4] Development of colorimetric and fluorescence-based detection methods that target precise recognition of bioactive metals such as copper (Cu$^{2+}$) and aluminum (Al$^{3+}$) is a topic of high interest among researchers.[5,6,7,8,9,10,11]

Cu$^{2+}$ is the third most abundant heavy metals after Fe$^{3+}$ and Zn$^{2+}$ in the human body. Several biological processes require Cu$^{2+}$ in optimum amounts.[12,13,14,15] The enzymes such as tyrosinase, lysyl oxidase, cytochrome c oxidase, and superoxide dismutase require Cu$^{2+}$ for redox reactions.[16,17] Even though Cu$^{2+}$ is potentially toxic, it is an essential element.[18] The deficiency of Cu$^{2+}$ leads to Menkes disease.[19,20] Whereas, accumulation of Cu$^{2+}$ is correlated to the Wilson disease,[21,22] Amyotrophic Lateral Sclerosis,[23,24] and Alzheimer's disease.[25,26] The crucial physiological relevance of Cu$^{2+}$ and its associated biomedical insinuations has resulted in substantial attention for the scheming of highly selective and sensitive copper chemosensors.[27]

Al$^{3+}$ is one of the most abundant biosphere elements at approximately 8% of the total mineral components. The neurotoxicity of Al$^{3+}$ has been known to humans for over one hundred years.[28,29] Al$^{3+}$ can cause many health issues, including Alzheimer's disease[30] and osteomalacia,[31] and increased risk of breast cancer.[32] The World Health Organization (WHO) recommends 3~10 mg of Al$^{3+}$ as an average daily intake. At the same time, the weekly tolerable dietary intake is about 7 mg kg$^{-1}$ body weight. Thus, recognizing Al$^{3+}$ in life and environmentally significant samples is critical to address.[33,34] Detection of Al$^{3+}$ has been challenging compared to other metal ions because of poor spectroscopic characteristics, meager coordination ability, and easy hydration.[35,36,37] Development of highly sensitive and selective chemosensors for Al$^{3+}$ detection is in great demand. Therefore, it is of substantial importance to build receptors for the selective detection of Al$^{3+}$.

According to the recent literature, noncyclic receptors containing multiple coordination sites have considerably improved in chemosensors design because of their ability to recognize different ionic and neutral molecules.[38,39,40] Such noncyclic receptors are well known to show interesting coordination properties due to heteroatoms in chelating sites. With this in mind, a Schiff base (receptor 3, Figure 1a) was prepared from isonicotinohydrazide and 2,4-dihydroxybenzaldehyde.
and evaluated as the target receptor for the metal ions. It was hypothesized that the N atoms of -CH=N- bond and the O atom of ortho-OH in receptor 3 could coordinate with the metal ion to form a stable complex. Herein, we report receptor 3 as a selective chemosensor for Cu\(^{2+}\) as it showed the distinctive red shift in the absorption maxima but without any fluorescence signal for the complex. Receptor 3 was found to be an excellent fluorescence sensor for Al\(^{3+}\) as evident from the chelation-enhanced fluorescence (CHEF) effect. The application of receptor 3 in fluorescence imaging was evaluated by confocal fluorescence microscopy in A549 cells, proving receptor 3 as a convenient tool for tracking Al\(^{3+}\) in vivo.

### 2. Material and methods

#### 2.1. Materials and instrumentation

All reagents were purchased from Sigma-Aldrich and were used as received unless stated otherwise. The reaction was carried out under an inert atmosphere (Argon gas), and monitoring the reaction using thin-layer chromatography (TLC) to confirm the formation of the product. The developed plates were visualized under UV light (254 nm). The synthesized compound was characterized by \(^1\)H and \(^{13}\)C NMR on a Jeol FT-NMR spectrometer (400 MHz; JEOL, Japan) in DMSO-\(d_6\). The chemical shifts (\(\delta\) ppm) and the coupling constants (J Hz) are reported. The UV-visible spectra were recorded on Shimadzu UV-24500 (Shimadzu, Japan) in the range of 200-600 nm at room temperature using a quartz cuvette of 1 cm optical path length. Fluorescence emission spectra were measured on the Agilent Cary Eclipse fluorescence spectrophotometer (Agilent Technologies, USA). The FT-IR spectra were recorded on a Nicolet iS5 FT-IR (ThermoScientific) spectrometer in the range of 400–4,000 cm\(^{-1}\) using KBr pellets. The JMS-700 MStation Mass Spectrometer (JEOL, Japan) was used for recording the high-resolution mass spectra of receptor 3. The mass spectra of 3.Al\(^{3+}\) complex were obtained by matrix-assisted laser deposition/ionization (time-of-
flight), MALDI-TOF mass spectrometry on a Bruker Autoflex speed TOF/TOF spectrometer (Bruker Daltonics, Bremen, Germany). The X-ray analysis was performed using a Bruker AXS D8 Quest CMOS diffractometer (Bruker, USA). The microplate Reader was Spectramax Plus 384 (Molecular Devices, USA), and the fluorescent microscope Zeiss-ScopeA1 (Germany) were used in the present study.

2.2. Synthesis of receptor 3

The Isonicotinohydrazide (0.198 g, 1.0 mmol) and 2,4-Dihydroxybenzaldehyde (0.200 g, 1.0 mmol) were reacted in ethanol (25 mL) at room temperature until the completion of the reaction (5 hr). The yellow color solid obtained was filtered and dried. Then, the obtained yellow color crud product was recrystallization from ethanol (Yield = 90 %). $^1$H NMR (400 MHz, DMSO-d$_6$): δ 6.36 (d, 2H, Ar-H), 7.36 (s, 1H, Ar-H), 7.82 (d, 2H, Ar-H), 8.54 (s, 1H, CH=N), 8.77 (d, 2H, Ar-H), 10.08 (s, 1H, Ar-OH), 11.29 (s, 1H, NH), 12.14 (s, 1H, Ar-OH); $^{13}$C NMR (100 MHz, DMSO-d$_6$): δ 102.61, 107.84, 110.40, 121.43, 131.20, 140.07, 150.29, 159.49, 161; Mass: Expt. m/z = 258.0870 (C$_{13}$H$_{11}$N$_3$O$_3$ [M+H]), Calc. m/z = 257.245.

2.3. UV–vis and fluorescence spectral measurements

All stock and working solutions were prepared using double distilled water and spectroscopic grade DMSO. A stock solution of receptor 3 (1 × 10$^{-3}$ M) was prepared in DMSO, and the corresponding working solutions (10 × 10$^{-6}$ M) were prepared simply by diluting with DMSO. Similarly, the stock solutions of cations (1 × 10$^{-2}$ M) were prepared in double-distilled water, and the corresponding working solutions (1 × 10$^{-3}$ M) were prepared by diluting with water. The UV-visible absorption and emission spectra of the receptor 3 (10 × 10$^{-6}$ M) dissolved in DMSO were recorded by adding the aqueous solution of various metal ions (Na$^+$, K$^+$, Ag$^+$, Cs$^+$, Sr$^{2+}$, Ca$^{2+}$, Co$^{2+}$, Cu$^{2+}$, Pd$^{2+}$, Mn$^{2+}$, Mg$^{2+}$, Ba$^{2+}$, Ni$^{2+}$, Zn$^{2+}$, Cd$^{2+}$, Pb$^{2+}$, Al$^{3+}$, Cr$^{3+}$, Fe$^{3+}$, Fe$^{2+}$) to examine the selectivity at room temperatures (298 K). For sensitivity study, the UV-visible absorption and emission titration experiments were accomplished through a stepwise addition of four equivalents of metals (1 ×10$^{-3}$ M) to a solution of receptor 3 (10 × 10$^{-6}$ M) in DMSO. The absorbance intensity and emission intensity were recorded in the range of 200-600 nm and 360-600 nm, respectively, alongside a reagent blank. Receptor 3 showed selectivity for detecting Cu$^{2+}$ in the absorption titrations and detecting Al$^{3+}$ in the fluorescence titrations. The binding stoichiometry of
receptor 3 with Cu$^{2+}$ ion (UV-Visible absorption spectroscopy and Al$^{3+}$ ion (fluorescence spectroscopy) were investigated by Job's plot method. A receptor 3 was titrated with successive addition of Cu$^{2+}$ or Al$^{3+}$ (1 µL, 1.0 x 10$^{-3}$ M) in water to a receptor 3 (1.0 mL) solution in DMSO. The collected data were processed using the Benesi-Hildebrand equation\cite{41} to determine the association constant ($K_a$) of analyte Cu$^{2+}$ and Al$^{3+}$ ion with receptor 3. The absorbance changes at 413 nm were used alongside a reagent blank for the detection of Cu$^{2+}$ ions. The fluorescence intensity was recorded at $\lambda_{ex}/\lambda_{em} = 343/473$ nm alongside a reagent blank with the excitation and emission slits set to 5.0 nm. The limit of detection (LOD) was estimated by applying the IUPAC recommended equation, LOD = 3$\sigma$/slope.\cite{42} Where $\sigma$ is the standard deviation of (n=10) blank samples and the slope is the slope for calibration curves.

\subsection*{2.4 Crystal growth for single X-ray crystallography}

The single crystals of receptor 3 were obtained by slow diffusion of ethanol in DMSO. However, several attempts to obtain the single crystals of the receptor 3 and Al$^{3+}$ complex (3.Al$^{3+}$), receptor 3 and Cu$^{2+}$ complex (3.Cu$^{2+}$) were unsuccessful. A suitable single crystal was carefully mounted for X-ray crystallography with the help of a trace of Fomblin oil on a Mitegen micromesh mount. Then it was transferred to the goniometer head with a fixed chi angle, a molybdenum $K_\alpha$ wavelength fine focus sealed X-ray tube ($\lambda = 0.71073$ Å), a single crystal curved graphite incident beam monochromator, a Photon100 CMOS area detector, and an Oxford Cryosystems low-temperature device. X-ray diffraction data were collected at 150 K using $\omega$ and $\phi$ scans to a maximum resolution of $\Theta = 33.221^\circ$. Data reduction, scaling, and absorption corrections were performed using SAINT (Bruker, V8.38A). The final completeness is 89.00 % out to 33.221$^\circ$ in $\Theta$. Multi-scan absorption correction was performed using SADABS 2016/2.\cite{43} The absorption coefficient $\mu$ of this material was 0.107 mm$^{-1}$ at this wavelength ($\lambda = 0.71073$ Å). The space group was determined based on systematic absences using XPREP\cite{44} as Pna2$_1$. The structure was solved using direct methods with ShelXS-97 and refined by full-matrix least-squares on F2 using ShelXL-2018/3 and the graphical interface ShelXLE (Rev937).\cite{45} All non-hydrogen atoms were refined anisotropically. Hydrogen atom positions were calculated geometrically and improved using a riding model. Mercury, PyMol, and POVRay were utilized for molecular measurements and molecular visualization.\cite{46}
2.5 Effect of pH on the detection of Al$^{3+}$ and reversibility of the receptor 3

The effect of pH (pH= 2-12) on receptor 3 was examined by fluorescence spectroscopy both in the absence and presence of Al$^{3+}$ ions. The pH was adjusted by adding perchloric acid and tetrabutylammonium hydroxide, respectively, in the HEPES buffered system. Reversibility is a critical aspect of the fluorescent recognition process. Hence, we examined the reversibility of receptor 3 in the presence of ethylenediaminetetraacetic acid disodium salt (EDTANa$_2$). For the reversibility study, EDTANa$_2$ (4 Equiv.) was added to the solution containing receptor 3. Al$^{3+}$ complex obtained by adding Al$^{3+}$ at 1:4 mole ratio. The reversibility was recorded by alternate additions of Al$^{3+}$ (4 Equiv.) and EDTANa$_2$ (4 Equiv.).

2.6 Determination of quantum yield of receptor 3 and receptor 3. Al$^{3+}$ complex

The quantum yields ($\Phi$) of receptor 3 and its complexes with Al$^{3+}$ were measured using the following formula.

$$\Phi_{\text{sample}} = \left( \frac{\text{OD}_{\text{standard}} \times A_{\text{sample}} \times \eta^2_{\text{sample}}}{\left( \text{OD}_{\text{sample}} \times A_{\text{standard}} \times \eta^2_{\text{standard}} \right)} \right) \times \Phi_{\text{standard}}$$

Where $A$ is the area under the emission spectral curve, OD is the compound's optical density at the excitation wavelength, and $\eta$ is the refractive index of the solvent. The quantum yield of receptor 3 and its complexes with Al$^{3+}$ was determined using β-Carboline ($\Phi = 0.570$) as the standard.$^{[47]}$

2.7 Cell culture studies

The cytotoxicity assay (MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay) and cell imaging study of receptor 3, Al$^{3+}$, and Al$^{3+}$ combined with receptor 3 was performed using A549 cells (Colorectal carcinoma cell line). The A549 cells were procured from the Korea cell line bank, Seoul, South Korea. Dulbecco Modified Eagle Medium (DMEM), fetal bovine serum (FBS), trypsin, 3-(4, 5-dimethyl thiazol-2yl)-2, 5-diphenyl tetrazolium bromide was procured from Thermo Fisher Scientific, USA. DMSO was procured from Biosesang, Korea. Cell culture plates and glass coverslips were procured from SPL Life Sciences, Korea. The A549 cells were grown in an incubator at 37 °C and
5% CO₂ using DMEM media containing 2 mM glutamine and 10% FBS. Cells were trypsinized for seeding at 70-90% of cell confluency.

2.8 Cytotoxicity assay and cell imaging

About 2,000 A549 cells per well were seeded in 96 well plates. After 24 h, the media containing receptor 3, Al^{3+} ion, and receptor 3 with Al^{3+} (1, 10, 25, and 50 µM) were added to the wells and incubated for another 24 h. Control wells were treated with equivalent volumes of dimethyl sulfoxide (DMSO). 200 µL of fresh media containing MTT solution and incubated for four hours at 37 °C. The absorbance was recorded at 570 nm to evaluate the cell viability. Each experiment was executed three times. The data analysis was performed using the Origin software.

For cell imaging, the A549 cells were seeded separately on poly-L-lysine coated 14 mm coverslips in 6 well plates and allowed to grow for 24 h. For cell imaging control experiments, 10 µM of Al^{3+} ion and 10 µM of receptor 3 were incubated separately for 30 min at 37 °C and 5% CO₂ in the dark. For cell imaging of the receptor 3 and Al^{3+} complex, 10 µM of Al^{3+} ion was incubated separately for 30 min. The media was then replaced with 10 µM of receptor 3 and incubated for an additional 30 min. The cells were washed with PBS buffer (pH =7.4), followed by fixing with 2% paraformaldehyde for 30 min after removing the media. Coverslip was mounted on a glass slide, and imaging was performed under a fluorescence microscope (Zeiss-ScopeA1, Germany). Images were taken through a green channel.

3. Results and discussion

3.1 Synthesis of receptor 3

The Schiff base (E)-N’-(2, 4-dihydroxybenzylidene) isonicotinohydrazide (receptor 3) was synthesized with a slight modification of the reported method through a direct reaction between isonicotinohydrazide and 2,4-dihydroxybenzaldehyde (Scheme 1) in ethanol with stirring and refluxing for 5 h. The molecular structure of receptor 3 was characterized by various spectral (FT-IR, ¹H NMR, ¹³C NMR, and Mass) data (Supporting information Figure S1-3) and finally confirmed by single-crystal X-ray crystallography (Figure 1b). The crystallographic data, selected bond parameters, and hydrogen-bond parameters are presented in Table S1, Table S2, and Table
S3, respectively. The CIF file for receptor 3 was placed in the Cambridge Structure Database (CCDC 2051947). The orange-colored crystal (0.55 × 0.42 × 0.05 mm\(^3\)) of receptor 3 demonstrated the orthorhombic system having a Pna\(_2\)\(_1\) space group within the unit cell. The ORTEP diagram with numbering and packing diagram is shown in Figure 1b. The receptor 3 in its free form displays the molecular association via intramolecular hydrogen bonding between the phenolic hydroxyl to imine nitrogen. Receptor 3 shows an intramolecular hydrogen bond (O(1)-H…N(1)) with a distance of 1.92 (3) Å and a bond angle of 150 (2) Å, which is in the expected range of such hydrogen bonds. Receptor 3 undergoes a solvent-assisted keto tautomerization suitable for the intramolecular charge transfer (ICT) process.\(^4\) The fluorescence intensity enhancement of receptor 3 in the presence of Al\(^{3+}\) is attributed to the ICT process.

### 3.2 Determination of selectivity of receptor 3 as a chemosensor for metal ions

The selectivity of receptor 3 for the cation detection was investigated by using the UV-visible absorption and fluorescence spectroscopy. The UV-Vis absorption spectra of receptor 3 (10 × 10\(^{-6}\) M, in DMSO) were recorded in the absence and presence of 4 equivalents of various metal ions, such as Na\(^+\), K\(^+\), Ag\(^+\), Cs\(^+\), Sr\(^{2+}\), Ca\(^{2+}\), Co\(^{2+}\), Cu\(^{2+}\), Pd\(^{2+}\), Mn\(^{2+}\), Mg\(^{2+}\), Ba\(^{2+}\), Ni\(^{2+}\), Zn\(^{2+}\), Cd\(^{2+}\), Pb\(^{2+}\), Al\(^{3+}\), Cr\(^{3+}\), Fe\(^{3+}\), Fe\(^{2+}\) (1 × 10\(^{-3}\) M, in H\(_2\)O).

![Figure 2](image)

**Figure 2.** (a) Changes in UV-Vis absorption spectra and (b) fluorescent intensity (\(\lambda_{\text{ex}} = 343\) nm, \(\lambda_{\text{em}} = 473\) nm) of receptor 3 (10 × 10\(^{-6}\) M) upon addition of 4 equivalents of different metal ions (1 × 10\(^{-3}\) M, in H\(_2\)O). Inset shows the color change of the solutions from colorless to pale green and fluorescence 'turn-on' effect.

Receptor 3 showed an absorption band at 343 nm, most likely due to the \(\pi\) to \(\pi^*\) transition (Figure 2a). Upon addition of Cu\(^{2+}\) ion, the absorption band at 343 nm was red-shifted to 413 nm.
(Δλ ≈ 70 nm), indicating that receptor 3 has a higher binding affinity towards Cu\(^{2+}\) ions than other surveyed metal ions. Receptor 3 showed two additional shouldering peaks at 428 nm and 475 nm to the major peak at 413 nm. In the presence of other metal ions, receptor 3 showed either no change or moderate decrease in the absorption intensity relative to the receptor. These results indicate the intramolecular charge transfer (ICT) character of the synthesized receptor 3 due to recognizing the Cu\(^{2+}\) ions through imine-N, amide carbonyl, and hydroxyl groups.\(^{[50]}\) The push-pull character of the ICT state due to the multiple coordination resulted in a red-shift (Δλ ≈ 70 nm). These results indicated that receptor 3 shows selectivity for Cu\(^{2+}\) ions.

The fluorescence emission spectra of receptor 3 (10 × 10\(^{-6}\) M, in DMSO) were recorded in the absence and presence of 4 equivalents of various metal ions, such as Na\(^{+}\), K\(^{+}\), Ag\(^{+}\), Cs\(^{+}\), Sr\(^{2+}\), Ca\(^{2+}\), Co\(^{2+}\), Cu\(^{2+}\), Pd\(^{2+}\), Mn\(^{2+}\), Mg\(^{2+}\), Ba\(^{2+}\), Ni\(^{2+}\), Zn\(^{2+}\), Cd\(^{2+}\), Pb\(^{2+}\), Al\(^{3+}\), Cr\(^{3+}\), Fe\(^{3+}\), Fe\(^{2+}\) (1 × 10\(^{-3}\) M, in H\(_2\)O). Receptor 3 showed a weak fluorescence emission at 473 nm upon excitation at 343 nm. Fascinatingly, the fluorescence was remarkably enhanced (~ 430-folds) in the presence of the Al\(^{3+}\) ions (Figure 2b). Interestingly, there was no change in the emission performance of receptor 3 in the presence of other cations, including Cu\(^{2+}\). The increase in fluorescence emission intensity was due to the azomethine group of receptor 3. Receptor 3 is reducibly fluorescent due to the C=N double bond's isomerization at the excited state and the excited-state proton transfer (ESPT). The ESPT involves the phenolic proton of the substituted dihydroxyl moieties of salicylaldehyde in the receptor 3. Upon stable chelation with Al\(^{3+}\), the C=N isomerization is inhibited. The coordination of receptor 3 with the Al\(^{3+}\) prohibits the ESPT process indicated by the fluorescence enhancement.\(^{[51,52,53]}\)

### 3.3 Binding mechanism and association constant

Job’s plot was used to determine the binding stoichiometry of receptor 3 with Cu\(^{2+}\) ions (UV-visible absorption spectroscopy) and Al\(^{3+}\) ions (fluorescence spectroscopy). The molar ratio of the metal ions was changed from 0.1 to 1.0 by keeping the total concentration of receptor 3 and Cu\(^{2+}\) ions at 10 × 10\(^{-6}\) M. The absorption maxima (λ = 413 nm) was observed when the molar ratio of the receptor 3 to Cu\(^{2+}\) was 0.33, indicating the formation of a 2:1 3.Cu\(^{2+}\) complex (Figure S4a). Similarly, the change fluorescence intensity (λ\(_{ex}\) = 343 nm, λ\(_{em}\) = 473 nm) was used to determine the binding stoichiometry of receptor 3 with Al\(^{3+}\). The molar ratio of Al\(^{3+}\) was changed from 0.1 to 1.0 by keeping the total concentration
of receptor 3, and Al$^{3+}$ ions at 10 x 10$^{-6}$ M. The emission maxima ($\lambda = 473$ nm) was observed when the molar ratio of the receptor 3 to Al$^{3+}$ was 0.33, indicating the formation of a 2:1 3.Al$^{3+}$ complex (Figure S4b). The complexes 3.Cu$^{2+}$ and 3.Al$^{3+}$ were obtained by refluxing the four equivalents of Cu$^{2+}$ and Al$^{3+}$ with receptor 3 in ethanolic solution. To ascertain the formation of receptor 3.Cu$^{2+}$ complex and 3.Al$^{3+}$ complex, we compared the FT-IR spectra for receptor 3 with that of respective complexes, as shown in Figure 3.

![Figure 3](image_url)

Figure 3. FT-IR spectra of (a) 3.Cu$^{2+}$ complex and (b) 3.Al$^{3+}$ complex recorded using the reflectance technique (4000–400 cm$^{-1}$).

The FT-IR spectrum of receptor 3 (Figure 3a) demonstrated signals at 3436.05, 3224.39 (amide), 3086.99 (intramolecular bonded O-H), and 1647.39 (imine) cm$^{-1}$. For the receptor 3.Cu$^{2+}$ complex, the FT-IR spectrum demonstrated a broad signal at 3422.06 (amide), no frequency for (intramolecular bonded O-H), and 1621.84 (imine) cm$^{-1}$. These results indicate that receptor 3 forms a stable complex with Cu$^{2+}$. Similarly, the FT-IR spectrum of receptor 3.Al$^{3+}$ complex demonstrated a broad signal at 3430.74 (amide), no frequency for (intramolecular bonded O-H), and 1623.77 (imine) cm$^{-1}$. The FT-IR spectrum shifts in the 3.Cu$^{2+}$ and 3.Al$^{3+}$ complexes compared to the receptor 3 confirmed the involvement of imine and amide groups in the complexation process.

As shown in Figure 4, the $^1$H NMR titration experiment was conducted using the mixture of 0.5% D$_2$O-d$_6$ in DMSO-d$_6$. The $^1$H NMR of receptor 3 demonstrated sharp peaks at $\delta_H$ 12.12 (amide N-H), $\delta_H$ 11.25, and $\delta_H$ 10.01 (phenolic -OH). The signals for one N-H proton and two -OH protons gradually disappeared upon the increasing amount of Al$^{3+}$ ions (0–1 Equiv). However, there was no significant change in the peak corresponding to imine group.
C-H (δH 8.52). These results indicate that the amide group, imine group, and phenolic moiety of receptor 3 take part in complexation with Al3+ ions. Further, the MALDI-TOF mass spectrum of receptor 3.Al3+ complex showed a signal at an m/z value of 544.129 and 561.133 (Figure S5). These results rationalize the formation of 2:1 complexation pattern for the 3.Al3+ complex. The paramagnetic property of Cu2+ results in the peak broadening in proton NMR spectra. Thus, the binding process of receptor 3 with the Cu2+ could not be monitored by NMR studies.54

Figure 4. 1H NMR spectral changes of receptor 3 in the mixture of 0.5% D2O-d2 in DMSO-d6, (a) 3 + Al3+ (0 Equiv) (b) 3 + Al3+ (0.25 Equiv), (c) 3 + Al3+ (0.5 Equiv), (d) 3 + Al3+ (1 Equiv.).

The association constants (Ka) of Cu2+ (UV-visible absorption spectroscopy) and Al3+ (fluorescence spectroscopy) complexes with receptor 3 were determined by Benesi-Hildebrand equations (Eq. S1, Eq. S2). As shown in Figure 5a, the receptor 3 (1.0 mL, 10 x 10−6 M) in DMSO was titrated with successive addition of Cu2+ (0 ~ 20 µL in H2O, c = 10 × 10−4 M) to measure the association constant (Ka). The absorbance values at absorption maxima (λ = 413 nm) were processed using the Benesi-Hildebrand equation (Eq. S1) to obtain the binding curve (Figure S6a). The Ka value for the complexation of Cu2+ with the receptor 3 was 1.3 × 104 M−1.

As shown in Figure 5b, the receptor 3 (1.0 mL, 10 x 10−6 M) in DMSO was titrated with successive addition of Al3+ (0 ~ 20 µL in H2O, c = 10 × 10−4 M). The changes in fluorescence intensity (λex = 343 nm, λem = 473 nm) were used to determine the Ka value by plotting the binding
curve (Figure S6b) according to the Benesi-Hildebrand equation (Eq. S2). The $K_a$ value for the complexation of $\text{Al}^{3+}$ with the receptor 3 was $4.8 \times 10^4 \text{M}^{-1}$. The binding affinity of $\text{Al}^{3+}$ for receptor 3 is 4-folds higher than that of $\text{Cu}^{2+}$ ions.

The computational studies have been done by applying the Density functional theory (DFT) using Gaussian 09. The molecular geometries of the singlet ground state of receptor 3, 3.$\text{Cu}^{2+}$ complex, and 3.$\text{Al}^{3+}$ complex were optimized using hybrid B3LYP functions with a 6-31G++(d,p) (C, H, N, O) and LANL2DZ (Cu, Al) basis sets.$^{[55]}$ The HOMO, LUMO results, information for bond length, and bond angles were obtained using Avogadro 1.2.0.$^{[56]}$ The 3D structures of the 3.$\text{Cu}^{2+}$ and 3.$\text{Al}^{3+}$ complexes were calculated by the DFT method using the 2:1 binding stoichiometry between receptor 3 and respective ions. The DFT computed structure of receptor 3 and its complexes are presented in Figure S7. The LUMO-HOMO bandgap ($\Delta E (\text{ev}) = E_{\text{LUMO}} - E_{\text{HOMO}}$) for receptor 3 was found to be 0.293.

In contrast, the LUMO-HOMO bandgap for 3.$\text{Cu}^{2+}$ and 3.$\text{Al}^{3+}$ complexes were 0.279 and 0.078, respectively. These results provided the basis for ascertaining the ICT between receptor 3 and $\text{Cu}^{2+}$ and $\text{Al}^{3+}$ ions. Comparing the electron densities of the HOMO and LUMO of receptor 3 with the 3.$\text{Cu}^{2+}$ complex supported the charge transfer occurs between the receptor and metal ions that further lowered the bandgap. The lowering of the bandgap upon complexation supported the red-shift of the absorbance of receptor 3 upon the addition of $\text{Cu}^{2+}$. On the contrary, the significant

---

**Figure 5.** Changes in (a) UV–vis absorption spectra and (b) Fluorescence spectra ($\lambda_{\text{ex}} = 343 \text{ nm}$, $\lambda_{\text{em}} = 473 \text{ nm}$) of receptor 3 (in 1 mL DMSO, $10 \times 10^{-6} \text{ M}$) up on successive addition of $\text{Cu}^{2+}$ (0 to 20 µL in H$_2$O, c = $10 \times 10^{-4} \text{ M}$), and $\text{Al}^{3+}$ (0 to 20 µL in H$_2$O, c = $10 \times 10^{-4} \text{ M}$), respectively.
decrease in the LUMO-HOMO bandgap ($\Delta E = 0.078$) indicated the formation of a relatively stable 3.$\text{Al}^{3+}$ complex as compared to the 3.$\text{Cu}^{2+}$ complex. The increase in fluorescence enhancement was complemented by a sharp decrease in energy HOMO-LUMO bandgap of the receptor 3.

### 3.5 Receptor 3 as a chemosensor for $\text{Cu}^{2+}$ and $\text{Al}^{3+}$ ions

The detection of the target analyte in the presence of the possibly competing analytes is a crucial aspect for any compound to be an excellent chemosensor. Therefore, we evaluated the specificity of receptor 3 for $\text{Cu}^{2+}$ in a competition experiment by recording the absorption ($\lambda = 413$ nm) receptor 3 in the presence of $\text{Cu}^{2+}$ (1 Equiv.) ion mixed with other cations (4 Equiv.). The results of the competition experiments are presented in **Figure S8a**. Similarly, we determined the efficiency of receptor 3 for detecting $\text{Al}^{3+}$ ions in a competition experiment by recording the fluorescence intensity ($\lambda_{\text{ex}} = 343$ nm, $\lambda_{\text{em}} = 473$ nm). As shown in **Figure S8b**, the fluorescence intensity for receptor 3 was measured in the presence of $\text{Al}^{3+}$ (1 Equiv.) ion mixed with other cations (4 Equiv.) The coefficient of variation in the change of absorbance and fluorescence intensity for $\text{Cu}^{2+}$ detection and $\text{Al}^{3+}$ detection, respectively, were below $\pm 10\%$. These results indicate that receptor 3 is a highly valuable chemosensor for detecting $\text{Cu}^{2+}$ by UV–vis absorption spectroscopy. Moreover, receptor 3 demonstrated its excellence in detecting $\text{Al}^{3+}$ ions with high specificity by fluorescence spectroscopy. Therefore, the high selectivity and specificity of receptor 3 for $\text{Cu}^{2+}$ and $\text{Al}^{3+}$ ions make it an excellent chemosensor for analytical applications. The absorbance ($\lambda = 413$ nm) and fluorescence intensity ($\lambda_{\text{ex}} = 343$ nm, $\lambda_{\text{em}} = 473$ nm) were plotted at various concentrations of $\text{Cu}^{2+}$ ions and $\text{Al}^{3+}$ ions, respectively, to obtain the calibration plots (Figure S9). The LOD for detecting $\text{Cu}^{2+}$ ions by UV–vis absorption spectroscopy was 1.86 $\mu$M. Whereas the LOD for the detection of $\text{Al}^{3+}$ ions by Fluorescence spectroscopy was 3.08 nM. The approximately 600-fold lower sensitivity of the receptor 3 for $\text{Al}^{3+}$ ions compared to $\text{Cu}^{2+}$ ions was attributed to the ~ 4-fold higher binding constant for 3.$\text{Al}^{3+}$ complex. It is important to notice that the receptor 3 demonstrated relatively lower detection limits for $\text{Cu}^{2+}$ and $\text{Al}^{3+}$ than some of the reported methods presented in **Table S4** and **Table S5**.

### 3.6 Effect of pH on the detection of $\text{Al}^{3+}$ and reversibility of the receptor 3
The effect of pH on receptor 3 for detecting Al$^{3+}$ ions was tested in the pH range of 2.0-12.0, as shown in Figure 6a. The emission intensity ($\lambda_{em} = 473$ nm) of receptor 3 did not change significantly with the pH change. However, equimolar Al$^{3+}$ ions changed the fluorescence intensity of receptor 3.Al$^{3+}$ complex considerably with the pH change. The receptor 3.Al$^{3+}$ complex's emission intensity was significantly high at pH 2.0 – 8.0 than pH 9.0 – 12.0. These results indicate that the interactions of the Al$^{3+}$ ions with receptor 3 are pH dependant. The decrease in emission intensity at higher pH values (9.0 – 12.0) specifies that the Al$^{3+}$ ions are freed from the complex, possibly due to more robust interactions with increased –OH levels. Nonetheless, receptor 3 demonstrated significant fluorescence intensity at pH 5.0 – 8.0 in the presence of Al$^{3+}$ ions, indicating its applicability for the detection of intracellular Al$^{3+}$ ions.

Figure 6. (a) Changes in fluorescence intensity of receptor 3 and receptor 3.Al$^{3+}$ complex in a binary mixture of DMSO:HEPES buffer (at various pH values) (9:1; v/v), (b) Fluorescence intensities ($\lambda_{ex} = 343$ nm, $\lambda_{em} = 473$ nm) of 3.Al$^{3+}$ complex (1:1) in the presence of EDTA for many cycles in DMSO.

It is of great advantage if a sensor can be reversible and reusable for sensing cations with high selectivity. A literature survey revealed that most of the reported Al$^{3+}$ ion sensors are based on the chemodosimetry that are typically irreversible.$^{[57]}$ Reversibility experiments were conducted by alternate additions of Al$^{3+}$ ion and EDTA (Figure 6b) to the solution of receptor 3. As shown in Figure 6b, the emission spectra of receptor 3 in the presence of Al$^{3+}$ (4 Equiv.) showed high emission intensity, which was quenched by EDTANa$_2$ (6 Equiv.) to the solution. However, further addition of Al$^{3+}$ (4 Equiv.) demonstrated fluorescence signal
but this time slightly lower than the previous cycle. Adding Al$^{3+}$ ions (4 Equiv.) causes emission enhancement, which can be quenched by adding another portion of EDTANa$_2$ (6 Equiv.). The reversibility of receptor 3 was repetitive, with a slight loss in fluorescence efficiency due to Al$^{3+}$/EDTANa$_2$ additions. The observed decrease in fluorescence intensity for each cycle results from an excess of EDTANa$_2$ (6 Equiv.) compared to Al$^{3+}$ (4 Equiv.). This experiment suggests that receptor 3 can act as a likely environmental receptor for Al$^{3+}$ detection.

3.7 Quantum yield of receptor 3 and receptor 3.Al$^{3+}$ complex

Quantum yields of receptor 3 and 3.Al$^{3+}$ complex were determined using norharmene as a standard. The quantum yield of receptor 3 ($\phi = 0.0021$) increases ~ 230 folds in the presence of Al$^{3+}$ ions to form receptor 3.Al$^{3+}$ complex ($\phi = 0.484$).

3.8 Application of receptor 3 in cell imaging application for detection of intracellular Al$^{3+}$ ions

![Figure 7](image)

Figure 7. (a) Cytotoxicity’s of receptor 3, Al$^{3+}$, and receptor 3 + Al$^{3+}$ on the A549 cells after 24 h, (b) bright-field images (top row) and green channel (bottom row), control, Receptor 3, Al$^{3+}$, and receptor 3 + Al$^{3+}$.

The complexation-induced fluorescence "turn on" or "turn off" effect is crucial for bioimaging applications of small molecular probes designed to detect the cationic analyte. Receptor 3 did not show any change in fluorescence intensity upon binding with the Cu$^{2+}$ ions. However, the
fluorescence signal of receptor 3 was increased by a few hundred folds in the presence of Al$^{3+}$ ions. Therefore, receptor 3 was used to detect Al$^{3+}$ ions in the living A549 cell lines to explore its biological applications. The MTT assay allowed us to estimate the cytotoxicity of receptor 3, Al$^{3+}$, and receptor 3.Al$^{3+}$ complex after exposure of cells to the concentrations of 1, 10, 25, and 50 µM for 24 h with DMSO as a control. As depicted in Figure 7a, the results are shown as the percent cell growth for each group compared to the control. There was no significant cell death even after 24 h of treatment at 1–25 µM of the receptor 3, Al$^{3+}$ ions, and the receptor 3.Al$^{3+}$ complex. However, upon treatment at 50 µM of receptor 3 and receptor 3.Al$^{3+}$ complex, about a 20% decrease in cell growth was observed. Hence, 10 µM of receptor 3 was used for cell imaging applications. As shown in Figure 7b, the cells did not show significant fluorescence upon incubation with Al$^{3+}$ ions (10 µM) alone. However, very weak fluorescence was observed upon incubation of cells with receptor 3 (10 µM). Interestingly, the fluorescence intensity was increased upon incubation of cells with receptor 3 (10 µM) in the presence of the Al$^{3+}$ ions (10 µM). These results indicated that receptor 3 has a high potential in the biological applications to detect Al$^{3+}$ in an in vitro assay.

4. Conclusions

In conclusion, we have developed a new optical receptor 3 based on Schiff base chemistry that demonstrated excellent selectivity and sensitivity towards Cu$^{2+}$ ions in UV–vis absorption spectroscopy. Whereas the developed receptor 3 showed excellent selectivity and sensitivity for the detection of Al$^{3+}$ ion by using fluorescence spectroscopy. In either case, the receptor did not show any interference from other tested metal ions. The 2:1 binding stoichiometry of receptor 3 and Al$^{3+}$ ions were confirmed by the FT-IR, NMR, and Mass spectroscopy. The reversibility of receptor 3 for Al$^{3+}$ ions in the presence of EDTA ensures its ability as an excellent probe for detecting Al$^{3+}$ in various samples, including living cells. Receptor 3 showed high selectivity for Al$^{3+}$ with a $K_a$ of 4.8 $\times$ 10$^4$ M$^{-1}$ and LOD of 3.0 nM. In comparison, the $K_a$ for Cu$^{2+}$ was 1.3 $\times$ 10$^4$ M$^{-1}$ and LOD of 1.9 µM. Receptor 3 is an excellent chemosensor for detecting Al$^{3+}$ ions indicated by its nanomolar range LOD. The quick response, easy-synthesis, and high sensitivity make receptor 3 an ideal sensor for detecting Cu$^{2+}$ and Al$^{3+}$ ions. Further, the synthesized receptor showed a highly sensitive and highly specific fluorescent 'turn-on' effect ($\lambda_{em} = 473$ nm) for the 2:1 binding with Al$^{3+}$ ions in a semi-aqueous medium and living cells.
