By using the foundational solutions of the linear variational equation of the unperturbed system along the homoclinic orbit as the local current coordinates system of the system in the small neighborhood of the homoclinic orbit, we discuss the bifurcation problems of non-degenerated homoclinic loops. Under the nonresonant condition, existence, uniqueness, and incoexistence of $k$-homoclinic loop and $k$-periodic orbit is obtained. Under the resonant condition, we study the existence of $1$-homoclinic loop, $1$-periodic orbit, $2$-fold $1$-periodic orbit, and two $1$-periodic orbits; the coexistence of $1$-homoclinic loop and $1$-periodic orbit. Moreover, we give the corresponding existence fields and bifurcation surfaces. At last, we study the stability of the homoclinic loop for the two cases of non-resonant and resonant, and we obtain the corresponding criterions.

1. Introduction

With the rapid development of nonlinear science, in the studies of many fields of research and application of medicine, life sciences and many other disciplines, there are a lot of variety high-dimensional nonlinear dynamical systems with complex dynamic behaviors. Homoclinic and heteroclinic orbits and the corresponding bifurcation phenomenons are the most important sources of complex dynamic behaviors, which occupy a very important position in the research of high-dimensional nonlinear systems. We know that in the study of high-dimensional dynamical systems of infectious diseases and population ecology we tend to ignore the stability switches and chaos when considered much more the non-linear incidence rate, population momentum, strong non-linear incidence rate, and so forth. The existence of transversal homoclinic orbits implies that chaos phenomenon occur; therefore, it is of very important significance to study the cross-sectional of homoclinic orbits and the preservation of homoclinic orbits for the system in small perturbation.

In addition, in the study of infectious diseases and population ecology systems, we sometimes require the existence of periodic orbits. And, homoclinic and heteroclinic orbits bifurcate to periodic orbits in a small perturbation means that we can get the required periodic solution only by adding a small perturbation when using the similar system which exists homoclinic or heteroclinic orbits to represent the natural system. This also explains the importance of homoclinic and heteroclinic orbits bifurcating periodic orbits in real-world applications.

Therefore, by using the research methods and theoretical results of qualitative and bifurcation problems of high-dimensional systems, especially the results of homoclinic and heteroclinic orbits and their bifurcations for the systems, to study the high-dimensional infectious disease dynamics and population ecology systems to reveal the complex dynamical behavior of the nonlinear dynamical systems and the corresponding reality systems is essential.

About the study of bifurcation problems of homoclinic and heteroclinic loops for two-dimensional systems, a large number of papers were obtained and achieved many good results (for some results see [1–6]); but for higher-dimensional nonlinear systems, due to the complexity, the results we see today are not abundant. Chow S. N., Deng B., and Fiedler B. discussed the bifurcation of non-degenerated homoclinic loop [7], but the research method is abstract,
and the results are based on the theory. Some subsequent studies are mostly based on the traditional Poincaré map construction method. Zhu [8] discussed the non-degenerated bifurcation problems of homoclinic loop of the system $\dot{z} = f(z, \alpha) + e g_\mu(z, \mu, e)$. Compared with [7], paper [8] described the bifurcation surface and bifurcation phenomenon by using the inherent eigenvalue, so that the results possess good operability.

In this paper, the bifurcation and stability problems of non-degenerated homoclinic loops under non-resonant and resonant conditions are considered. The method to establish the local coordinates system in the tubular neighborhood of homoclinic loop used in [8] is simplified here. In [8], the author used the generalized Floquet method to establish local coordinate systems and Poincaré map. Here, we use the foundational solutions of the linear variational equation of the unperturbed system along the homoclinic orbit as the local coordinates system of the perturbed system in the small neighborhood of the homoclinic orbit. The Poincaré Maps and bifurcation equations obtained by this method are more simple and convenient for analysis than [8]. Besides, this method does not only have important significance in theory, but it can also be operated well in applications.

2. Hypotheses

Suppose the following $C^r$ system:

$$\dot{z} = f(z),$$

where $r \geq 4, z \in \mathbb{R}^{m+n}$ satisfies the following hypotheses.

(H1) (Hyperbolicity) $z = 0$ is a hyperbolic equilibrium of system (1), the stable manifold $W^s_0$ and the unstable manifold $W^u_0$ of $z = 0$ are $m$-dimensional and $n$-dimensional, respectively. Moreover, $Df(0)$ has simple eigenvalues $\lambda_1, -\rho_1$, such that, any remaining eigenvalue $\sigma$ of $Df(0)$ satisfies either $\Re \sigma < -\rho_1 < 0$ or $\Re \sigma > \lambda_1 > 1$, for some positive numbers $\lambda_0$ and $\rho_0$.

(H2) (Nondegeneration) System (1) has a homoclinic loop $\Gamma = \{ z = r(t) : t \in \mathbb{R}, |r(\pm \infty)| = 0 \}$, for any $P \in \Gamma$, codim $(T_p W^s_0 + T_p W^u_0) = 1$.

(H3) (Strong inclination)

$$\lim_{t \to +\infty} (T_{r(t)} W^s_0 + T_{r(t)} W^u_0) = T_0 W^s_0 \oplus T_0 W^u_0,$$

$$\lim_{t \to -\infty} (T_{r(t)} W^s_0 + T_{r(t)} W^u_0) = T_0 W^s_0 \oplus T_0 W^s_0,$$

where, $W^s_0$ and $W^u_0$ are the stable manifolds and the strong stable manifold of $z = 0$, respectively. $T_0 W^s_0$ is the generalized eigenspace corresponding to those eigenvalues with smaller real part than $-\rho_0$, and $T_0 W^u_0$ is the generalized eigenspace corresponding to those eigenvalues with larger real part than $\lambda_0$.

Let $e^s = \lim_{t \to +\infty} r(t)/|r(t)|, e^u \in T_0 W^u_0$ and $e^- \in T_0 W^s_0$ be unit eigenvectors corresponding to $\lambda_1$ and $-\rho_1$, respectively. span$(T_0 W^u_0, e^u) = T_0 W^u_0$ and span$(T_0 W^s_0, e^-) = T_0 W^s_0$.

Now, we consider the bifurcation problems of the following $C^r$ perturbation system:

$$\dot{z} = f(z) + g(z, \mu),$$

where $\mu \in \mathbb{R}^l, l \geq 2, 0 \leq |\mu| < 1$, and $g(0, \mu) = g(z, 0) = 0$.

3. Local Coordinates

Suppose that the neighborhood $U$ of $z = 0$ is small enough and (H1)~(H3) are established, then, for $|\mu|$ is small enough, we can introduce a $C^r$ change such that system (3) has the following form in $U$:

$$\begin{align*}
\dot{x} &= [\lambda_1(\mu) + \cdots] x + \text{h.o.t.}, \\
\dot{y} &= [-\rho_1(\mu) + \cdots] y + \text{h.o.t.}, \\
\dot{u} &= [B_1(\mu) + \cdots] u + \text{h.o.t.}, \\
\dot{v} &= [-B_2(\mu) + \cdots] v + \text{h.o.t.},
\end{align*}$$

where $\lambda_1(0) = \lambda_1$, $\rho_1(0) = \rho_1$, $Re \sigma(B_1(0)) > \lambda_0$, $Re \sigma(-B_2(0)) < -\rho_0$, $z = (x, y, u^*, v^*)^T, x \in \mathbb{R}^l, y \in \mathbb{R}^l, u \in \mathbb{R}^{l-1}, v \in \mathbb{R}^{l-1},$ and * means transposition. Moreover, in $U$, we suppose that the instable manifold, the stable manifold, the strong instable manifold, the strong stable manifold and the local homoclinic orbits have the following forms, respectively.

$$\begin{align*}
W^u_{\text{loc}} &= \{ y = 0, v = 0 \}, \\
W^s_{\text{loc}} &= \{ x = 0, u = 0 \}, \\
W^{uu}_{\text{loc}} &= \{ x = x(u), y = 0, v = 0 \}, \\
W^{us}_{\text{loc}} &= \{ x = 0, u = 0, y = y(v) \}, \\
\Gamma \cap W^u_{\text{loc}} &= \{ y = 0, v = 0, u = u(x) \}, \\
\Gamma \cap W^u_{\text{loc}} &= \{ x = 0, u = 0, v = v(y) \},
\end{align*}$$

where, $x(0) = \hat{x}(0) = 0, y(0) = \hat{y}(0) = 0, u(0) = \hat{u}(0) = 0, v(0) = \hat{v}(0) = 0$.

Denote $r(t) = (r^x(t), r^y(t), (r^u(t))^*, (r^v(t))^*)^T$. Taking a time transformation if necessary, we may assume $r(-T) = (\delta, 0, 0^*, 0^*)^T, r(T) = (0, \delta, 0^*, \delta^*)^T$, where $\delta$ is small enough such that $[x, y, u, v] : |x|, |y|, |u|, |v| < 2\delta \in U, [\delta] = O(\delta^m), [\delta^*] = O(\delta^m\delta)$, $\omega = \min \{ |Re \sigma(B_2(\mu))/\rho_1(\mu)|, Re \sigma(B_1(\mu))/\lambda_1(\mu) \} > 1$.

Consider the linear system

$$\dot{z} = (Df(r(t))) z.$$
Similar to [9–11], system (6) has a fundamental solution matrix \( Z(t) = (z_1(t), z_2(t), z_3(t), z_4(t)) \), satisfying

\[
\begin{align*}
z_1(t) & \in (T_{t(0)}W^s)^c \cap (T_{t(t)}W^u)^c, \\
z_2(t) & = \frac{r(t)}{|r(t)|} \in (T_{t(0)}W^s) \cap (T_{t(t)}W^u), \\
z_3(t) & = z_3^1(t), \ldots, z_3^{n-1}(t) \in (T_{t(0)}W^s)^c \cap (T_{t(t)}W^u)^c, \\
z_4(t) & = z_4^1(t), \ldots, z_4^{n-1}(t) \in (T_{t(0)}W^s) \cap (T_{t(t)}W^u)^c \\
& = T_{t(t)}W^u,
\end{align*}
\]

where \( w_2 < 0, w_12 \neq 0 \), \( w_{3,1} \neq 0 \), and for \( \delta \) small enough, \( |w_{3,1}|, |w_{3,2}| < 1, i \neq 1; |w_{12,3}| < 1, i = 3, 4; |w_{3,5,1}| < 1, i \neq 3; |w_{12,4}| < 1, i < 4 \).

Thus, we may select \( (z_1(t), z_2(t), z_3(t), z_4(t)) \) as a local coordinate system along \( \Gamma \).

Denote \( \Phi(t) = (\phi_1(t), \phi_2(t), \phi_3(t), \phi_4(t)) = (Z^{-1}(t))^* \). So, \( \Phi(t) \) is a fundamental solution matrix of the adjoint system \( \phi = -(DF(r(t)))^* \phi \) of (6). And \( \Phi(t) \in (T_{t(t)}W^s)^c \cap (T_{t(t)}W^u)^c \) is bounded and tends to zero exponentially as \( t \to \infty \) [8, 9, 12, 13].

Denote \( w_{12} = |w_{12}| \),

\[
\Delta = \begin{cases} 1, & w_{12} > 0 \\
-1, & w_{12} < 0 \end{cases}
\]

We say that \( \Gamma \) is non-twisted as \( \Delta = 1 \), and twisted as \( \Delta = -1 \). In this paper, we only consider the non-twisted case.

### 4. Poincaré Maps and Bifurcation Equations

Denote \( N = \{n_1, 0, n_3^4, n_4^5\}^*, n_3 = \{n_3^1, \ldots, n_3^{n-1}\}^* , n_4 = \{n_4^1, \ldots, n_4^{n-1}\}^* \), \( h(t) = r(t) + Z(t)N = r(t) + z_3(t)n_1 + z_4(t)n_4 \). Let \( S_\delta = \{z = h(T) : |x|, |y|, |u|, |v| < 2\delta \} \) be the cross sections of \( \Gamma \) at \( T = T \) and \( T = -T \), respectively, where, \( \delta \) is small enough such that \( S_\delta \bigcap U \subset \Gamma \).

Now, we set up Poincaré map \( F = F_1 \circ F_2 : S_0 \to S_0 \), where the map \( F_2 : S_0 \to S_1 \) is defined by the approximate solution of (3) in the small neighborhood \( U \) of \( z = 0 \) (similarly, we can set up the map by the flow of the linear system of (4) in the small neighborhood \( U \) of \( z = 0 \)), \( F_1 : S_1 \to S_0 \) is set up by the solution manifold of (3) in the tubular neighborhood of \( \Gamma \).

#### 4.1. The Relationship between the Two Kinds of Coordinates.

Denote \( q_{2j} \in S_0, q_{2j+1} \in S_1, j = 0, 1, 2, \ldots \). Let \( F_0(q_{2j}, q_{2j+1}) = q_{2j+1} \), and \( F_1(q_{2j+1}) = q_{2j+2} \). Now, we can set up the relationship between the two kinds coordinates \( (x_j, y_j, u_j^*, v_j^*) \) and \( (n_j, 0, n_{3j}, n_{4j}) \) of \( q_i, i = 0, 1, 2, \ldots \).

Let

\[
q_{2j} = r(T) + Z(T)N_{2j},
q_{2j+1} = r(-T) + Z(-T)N_{2j+1},
\]

where \( N_{2j} = (n_{2j,1}, 0, n_{2j,3}, n_{2j,4}^* \), \( N_{2j+1} = (n_{2j+1,1}, 0, n_{2j+1,3}, n_{2j+1,4}^* \), \( j = 0, 1, 2, \ldots \).

Using the expressions of \( Z^{-1}(T), Z^{-1}(-T) \), and by simple calculation, we have \( y_j = \delta, x_{2j+1} = \delta \), and

\[
\begin{align*}
n_{2j,1} & = x_{2j} - w_{33}^{-1}u_{2j}, \\
n_{2j,3} & = w_{33}^{-1}u_{2j}, \\
n_{2j,4} & = w_{24}^{-1}v_{2j+1}, \\
n_{2j+1,1} & = w_{12}^{-1}(y_{2j+1} - w_{24}^{-1}v_{2j+1}), \\
n_{2j+1,3} & = u_{2j+1} - w_{12}^{-1}(y_{2j+1} - w_{24}^{-1}v_{2j+1}) + aw_{44}^{-1}v_{2j+1}, \\
n_{2j+1,4} & = w_{44}^{-1}v_{2j+1},
\end{align*}
\]

where \( a = -w_{43} + w_{13}w_{24}^{-1}w_{24} - w_{24}^{-1}w_{24}^{-1}w_{43} + w_{11}w_{12}^{-1}w_{24} \).

#### 4.2. Set Up \( F_1 \).

Substitute \( z = h(t) \) into (3), and use \( r(t) = f(r(t)), Z(t) = DF(r(t))Z(t) \), we have

\[
Z(t)(n_1, 0, n_3, n_4)^* = g_{\mu}(r(t), 0) \mu + \text{h.o.t.}
\]
Multiplying both sides by $\Phi^*(t)$, and using $\Phi^*(t)Z(t) = I$, we have $(n_1, 0, n_3, n_4)^* = \Phi^*(t)g_\mu(\tau(t), 0)\mu + \text{h.o.t.}$, that is,

$$n_i = \Phi^*_i(t)g_\mu(\tau(t), 0)\mu + \text{h.o.t.}, \quad i = 1, 3, 4. \quad (14)$$

Thus, from the flow of (14), we define the map $F_1 : S_1 \mapsto S_0, N(\tau(T)) \mapsto N(T)$ which has the following form

$$n_i(T) = n_i(-T) + M_i(\mu) + \text{h.o.t.}, \quad i = 1, 3, 4, \quad (15)$$

where $M_i = \int_{-\infty}^{+\infty} \Phi^*_i(t)g_\mu(\tau(t), 0)dt, i = 1, 3, 4$, is said to the Melnikov vectors [8, 9, 14, 15].

4.3. Set Up $F_0$. Now, we consider the map $F_0 : S_0 \mapsto S_1, q_0 \mapsto q_1$ defined by the orbit of (4). For convenience, we assume that $\rho_1 \geq \lambda_1$. Obviously, for $\mu$ small enough, $\text{Re} \sigma(B_2(\mu)) > \rho_0 > \lambda_1(\mu)$.

Let $\tau$ be the flying time from $q_0$ to $q_1$, and $s = e^{-\lambda_1(\mu)\tau}$ be called Silnikov time. By (1), in $U$, we get

$$x = e^{\lambda_1(\mu)(\tau-T)}x_1 + \int_{T+\tau}^{t} (\text{h.o.t.}) e^{\lambda_1(\mu)(t-\xi)}d\xi, \quad (16)$$

$$y = e^{-\rho_i(\mu)(\tau-T)}y_0 + \int_{T+\tau}^{t} (\text{h.o.t.}) e^{-\rho_i(\mu)(t-\xi)}d\xi, \quad (17)$$

$$u = e^{B_i(\mu)(\tau-T)}u_1 + \int_{T+\tau}^{t} (\text{h.o.t.}) e^{B_i(\mu)(t-\xi)}d\xi, \quad (18)$$

$$v = e^{-B_i(\mu)(\tau-T)}v_0 + \int_{T+\tau}^{t} (\text{h.o.t.}) e^{-B_i(\mu)(t-\xi)}d\xi, \quad (19)$$

Neglecting the higher order terms, the Poincaré map $F_0 : q_0 \mapsto q_1$ from $S_0$ to $S_1$ defined by (16) as follows:

$$x_0 \approx s\delta, \quad y_1 \approx s^{\rho(\mu)/\lambda(\mu)}\delta, \quad u_0 \approx s^{B(\mu)/\lambda(\mu)}u_1, \quad v_1 \approx s^{B_i(\mu)/\lambda_i(\mu)}v_0, \quad (s, u_1, v_0) \quad (20)$$

Let $\tau$ be the flying time from $q_0$ to $q_1$, and $s = e^{-\lambda_1(\mu)\tau}$ be called Silnikov time. By (4), in $U$, we get

$$\delta = e^{-\lambda_1(\mu)\tau}\delta + \int_{T}^{t} (\text{h.o.t.}) e^{-\lambda_1(\mu)(t-\xi)}d\xi, \quad (21)$$

Substituting (11), (12), and (17) into (18), and neglecting the higher order terms, the Poincaré map $F = F_1 * F_0 : q_0 \in S_0 \mapsto q_2 \in S_0$ is given by

$$n_{2,1} = w^{-1}_{12}\delta s^{\rho(\mu)/\lambda(\mu)} + M_1(\mu) + \text{h.o.t.}, \quad (22)$$

$$n_{2,3} = u_1 - \delta_u + (w_{11}w_{23}u_{21} - w_{13})w^{-1}_{12}\delta s^{\rho(\mu)/\lambda(\mu)}$$

$$+ M_3(\mu) + \text{h.o.t.}, \quad (23)$$

$$n_{2,4} = w^{-1}_{44}s^{B_i(\mu)/\lambda_i(\mu)}v_0 + M_4(\mu) + \text{h.o.t.} \quad (24)$$

4.4. F and Bifurcation Equation. Let $F_1(q_1) = q_2$, by (15)

$$n_{2,j} = n_{1,j} + M_j(\mu) + \text{h.o.t.}, \quad j = 1, 3, 4. \quad (25)$$

Substituting (11), (12), and (17) into (18), and neglecting the higher order terms, the Poincaré map $F = F_1 * F_0 : q_0 \in S_0 \mapsto q_2 \in S_0$ is given by

$$n_{2,1} = w^{-1}_{12}\delta s^{\rho(\mu)/\lambda(\mu)} + M_1(\mu) + \text{h.o.t.}, \quad (26)$$

$$n_{2,3} = u_1 - \delta_u + (w_{11}w_{23}u_{21} - w_{13})w^{-1}_{12}\delta s^{\rho(\mu)/\lambda(\mu)}$$

$$+ M_3(\mu) + \text{h.o.t.}, \quad (27)$$

$$n_{2,4} = w^{-1}_{44}s^{B_i(\mu)/\lambda_i(\mu)}v_0 + M_4(\mu) + \text{h.o.t.} \quad (28)$$

Thus, for $s \geq 0$, there is a one to one correspondence between the 1-homoclinic loop and 1-periodic orbit of (3) and the solution $Q = (s, u_1, v_0)$ of the following equation:

$$(G_1, G_3, G_4) = 0. \quad (29)$$

Equation (21) is called bifurcation equation.

5. Nonresonant Bifurcations

(H4) (Nonresonant condition) $\lambda_1 < \rho_1$.

Obviously, for $\mu$ small enough, we may assume $\rho_1(\mu) > \lambda_1(\mu)$.

Theorem 1. Suppose that hypotheses (H1)–(H4) are valid, then if $|\mu|$ is small enough, the system (3) exists no more than one 1-homoclinic loop or one 1-periodic orbit in the neighbourhood of $\Gamma$. Moreover, the 1-homoclinic loop and the 1-periodic orbit cannot coexist.

Proof. Consider the solution of (21). Let $\tilde{G} = \partial (G_1, G_3, G_4)/\partial Q$. From (20), we have $\tilde{G}_{Q=0,\mu=0} = \text{diag}(-\delta, 1, -\delta)$ + $(\delta_i)$, where elements of $(\delta_i)$ are all zero except $g_{31} = w_{31}\delta$. Therefore, det $\tilde{G} \neq 0$. According to the implicit function theorem, in the neighbourhood of $(Q, \mu) = (0, 0)$, (21) exists a unique solution

$$s = s(\mu), \quad u_1 = u_1(\mu), \quad v_0 = v_0(\mu), \quad (22)$$

which satisfies $s(0) = 0, u_1(0) = 0, v_0(0) = 0$.

If $s = 0$, then the solution (22) corresponds to a 1-homoclinic loop of the system (3), that is, the homoclinic loop $\Gamma$ is persistent.

If $s > 0$, then the solution (22) corresponds to a 1-periodic orbit of the system (3), that is, the homoclinic orbit $\Gamma$ bifurcates to a periodic orbit.

The proof is complete. \[\square\]

Theorem 2. If $M_1 \neq 0$, then there exists a $(l-1)$-dimensional surface $L \subset R^l$ in the small the neighbourhood of $\mu = 0$, such that when $\mu \in L$ and $|\mu| \ll 1$, the system (3) exists a unique homoclinic loop near $\Gamma$. If $M_1 \mu > 0$, then the system (3) exists a unique periodic orbit near $\Gamma$. If $M_1 \mu < 0$, then the system (3) has no any homoclinic loop and periodic orbit near $\Gamma$. L is called bifurcation surface, its analytical expression is $M_1(\mu) + \text{h.o.t.} = 0$. \[\square\]
Proof. From (20), for $s \geq 0$ and $|\mu|$ small enough, equations $G_3 = 0$ and $G_4 = 0$ always have a unique solution $u_1 = u_1(s, \mu), v_0 = v_0(s, \mu)$. Substituting into $G_1 = 0$, we get

$$\delta \left( w_{12}^{-1} s_1^{\rho_1(\mu), \lambda(\mu)}(s) - s \right) + M_1 \mu + \text{h.o.t.} = 0 \quad (23)$$

If $M_1 \neq 0$, then, according to the implicit function theorem, in the neighbourhood of $\mu = 0$, the equation $M_1 \mu + \text{h.o.t.} = 0$ defines a unique ($l - 1$)-dimensional surface $L \subset \mathbb{R}^l$, such that if $\mu \in L$ and $|\mu| \ll 1$, (23) has the solution $s = 0$, the uniqueness can be obtained by the Theorem 1.

If $M_1 \mu > 0$, then (23) has the small positive solution $s = \delta^{-1} M_1 \mu + \text{h.o.t.}$.

If $M_1 \mu < 0$, then (23) has nonzero negative solution $s = \delta^{-1} M_1 \mu + \text{h.o.t.}$. At present, the system (3) has neither homoclinic loop nor periodic orbit near the neighbourhood of $\Gamma$.

The proof is complete. \(\square\)

Now, we consider the nonexistence of $k$-homoclinic loop and $k$-periodic orbit, where $k > 1$. Firstly, we consider the case of $k = 2$.

We rewrite the time from $q_0$ and $q_1$ as $r_1, s_1 = e^{-\lambda(\mu)r_1}$. Suppose $F_0(q_2) = q_3, F_1(q_3) = q_4 = q_0$, and let $r_2$ be the time from $q_2$ to $q_3$. $s_2 = e^{-\lambda(\mu)r_2}$.

Similar to the previous discussion, we can get its associated successor function $G^2 = (G_1^1, G_1^2, G_1^3, G_2^1, G_2^2, G_2^3)$ as follows:

$$G_1^1 = \delta \left( w_{12}^{-1} s_1^{\rho_1(\mu), \lambda(\mu)}(s_1) - s \right) + M_1 \mu + \text{h.o.t.,}$$

$$G_1^3 = u_1 - \delta_\mu + \left( w_{11} w_{23} w_{21}^{-1} - w_{13} \right) w_{12}^{-1}s_1^{\rho_1(\mu), \lambda(\mu)} - w_{33}^{-1}s_2^{\rho_1(\mu), \lambda(\mu)} u_3 + M_3 \mu + \text{h.o.t.,}$$

$$G_3 = v_2 + \delta_\mu + w_1^{-1} s_2 + w_1^{-1} s_1^{\rho_1(\mu), \lambda(\mu)} v_0 + M_4 \mu + \text{h.o.t.,}$$

$$G_1^2 = \delta \left( w_{12}^{-1} s_2^{\rho_1(\mu), \lambda(\mu)}(s_2) - s \right) + M_1 \mu + \text{h.o.t.,}$$

$$G_3 = u_3 - \delta_\mu + \left( w_{11} w_{23} w_{21}^{-1} - w_{13} \right) w_{12}^{-1}s_2^{\rho_1(\mu), \lambda(\mu)} - w_{33}^{-1}s_1^{\rho_1(\mu), \lambda(\mu)} u_1 + M_3 \mu + \text{h.o.t.,}$$

$$G_4 = v_0 + \delta_\mu + w_1^{-1} s_1 + w_1^{-1} s_2^{\rho_1(\mu), \lambda(\mu)} v_2 + M_4 \mu + \text{h.o.t.,}$$

(24)

Denote $Q_2 = (s_1, s_2, u_1, v_0, u_2, v_2)$, $\partial Q_2 / \partial \mu = (G_2^1, G_2^2, G_2^3, G_4^1, G_4^2, G_4^3)/(\delta_{ij})_{(\mu)}$, then $G_2^2 |_{Q_2=0, \mu=0} = \text{diag}(-\delta_\mu, -\delta_\mu, -\delta_\mu, 1, -1, -1, -1, 1)$, where the elements of $(\delta_{ij})_{(\mu)}$ are all zero except $\delta_{41} = \mu_{14}$, $\delta_{21} = \mu_{12}$.

Hence, $\text{det} G_1^1 / Q_2 = 0, \mu = 0 \neq 0$. According to the implicit function theorem, near $(Q_2, \mu) = (0, 0)$, the bifurcation equation

$$(G_1^1, G_1^3, G_1^2, G_2^1, G_2^2, G_2^3, G_4^2) = 0 \quad (25)$$

has a unique solution

$$s_1 = s_1(\mu), \quad u_1 = u_1(\mu), \quad v_0 = v_0(\mu),$$

$$s_2 = s_2(\mu), \quad u_3 = u_3(\mu), \quad v_2 = v_2(\mu), \quad (26)$$

which satisfies $s_1(0) = 0, u_1(0) = 0, v_0(0) = 0, s_2(0) = 0, s_3(0) = 0, v_2(0) = 0$.

If $s_1 = s_2 = 0$, then the homoclinic loop of the system (3) which the solution (26) corresponds to is the 1-homoclinic loop.

Because 1-periodic orbit obviously corresponds to the solution $s_1 = s_2 > 0$ of (26) then, by the uniqueness of solution, the system (3) has no 2-periodic orbit.

If $s_1 > 0, s_2 = 0$, or $s_1 = 0, s_2 > 0$, then $G_1^1 = 0$ and $G_2^1 = 0$ will get the contradiction.

And, so, for any $k > 1$, we have the following.

Theorem 3. Suppose that (H1)–(H4) are fulfilled, $k > 1$, then the system (3) does not have any $k$-homoclinic loop and $k$-periodic orbit for $|\mu|$ sufficiently small.

6. Resonance Bifurcation

We say that the homoclinic loop is Resonance if $\lambda_1 = \rho_1$. For convenience, we assume the resonant condition has the following form.

(H5) (Resonant condition) $\lambda_1 = \rho_1 = \lambda, \lambda_1(\mu) = \lambda, \rho_1(\mu) = \lambda + \alpha(\mu) \lambda$, where $\alpha(\mu) \in \mathbb{R} \setminus \{0\}$, $|\alpha(\mu)| \ll 1$, and $\alpha(0) = 0$.

At first, we discuss the bifurcations of 1-homoclinic loop and 1-periodic orbit. Now, the bifurcation equation has the following form:

$$G_1 = \delta \left( w_{12}^{-1} s^{1+\alpha(\mu)}(s) - s \right) + M_1 \mu + \text{h.o.t.} = 0,$$

$$G_3 = u_1 - \delta \mu + \left( w_{11} w_{23} w_{21}^{-1} - w_{13} \right) w_{12}^{-1} s^{1+\alpha(\mu)} - w_{33}^{-1} s^{\rho_1(\mu), \lambda(\mu)} u_3 + M_3 \mu + \text{h.o.t.} = 0,$$

$$G_4 = -v_0 + \delta \mu + w_1^{-1} s + w_1^{-1} s^{\rho_1(\mu), \lambda(\mu)} v_0 + M_4 \mu + \text{h.o.t.} = 0.$$

(27)

Similarly for $s \geq 0$, there is a one to one correspondence between the 1-homoclinic loop and 1-periodic orbit of (3) and the solution $Q = (s, u_1(s), v_0)$ of the bifurcation equation (27). It is Easy to see that, for the sufficiently small $s \geq 0$ and $|\mu|$, equations $G_3 = 0, G_4 = 0$ of (27) always have a unique solution $u_1 = u_1(s, \mu), v_0 = v_0(s, \mu)$. Substituting it into $G_1 = 0$, we get

$$s^{1+\alpha(\mu)} = w_{12} \left( s - \delta^{-1} M_1 \mu \right) + \text{h.o.t.} \quad (28)$$

Denote $N(s) = s^{1+\alpha(\mu)}, V(s) = w_{12}(s - \delta^{-1} M_1 \mu) + \text{h.o.t.}$, we have the following conclusion.

Lemma 4. Suppose (H1)–(H3) and (H5) are fulfilled, then, for $0 < s_0, |\mu| \ll 1$, the necessary condition of $N(s)$ and $V(s)$ are tangent at $s_0$ is that $\alpha(\mu) M_1 \mu > 0$. Meanwhile, if $\Delta = 1$ and $0 < s_0 \ll 1$, $N(s)$, and $V(s)$ are tangent at $s_0$ if only if $\alpha(\mu) (1 - w_{12}) > 0$, and

$$M_1 \mu = \beta_1(\mu) \quad (29)$$

$$:= \delta \alpha(\mu) \left( 1 + \alpha(\mu) \right)^{-1/|\alpha(\mu)|} w_{12}^{1/|\alpha(\mu)|} + \text{h.o.t.}$$
Proof. \( N(s) \) and \( V(s) \) are tangent at \( s = s_0 \) if and only if \( N(s_0) = V(s_0), N'(s_0) = V'(s_0) \), that is,

\[
\begin{align*}
\sigma_0^{1+\varepsilon_\mu} &= \omega_{12} (s_0 - \delta^{-1} M_1 \mu) + \text{h.o.t.},
(1 + \alpha(\mu)) \delta_{0}^{\alpha(\mu)} = \omega_{12}.
\end{align*}
\]

Solving the above equations, we have \( s_0 = ((1 + \alpha(\mu))/\alpha(\mu)) \delta^{-1} M_1 \mu + \text{h.o.t.} \). Substituting it into (30), (29) is fulfilled.

The proof is complete.

Suppose \( \Sigma_1 \) is the surface defined by (29), \( \Sigma_2(s) \) is the surface defined by (28), \( \Sigma_2 = \Sigma_2(0) \). Besides, if \( \mu \in \Sigma_2 \), (28) is turned to \( M_1 \mu = \beta_2(\mu) \).

**Theorem 5.** Suppose (H1)–(H3) and (H5) are fulfilled, \( \alpha(\mu) > 0, 0 < \omega_{12} < 1 \). If \( M_1 \neq 0 \), then, in the neighborhood of \( \mu = 0 \), there exists two \((l - 1)\)-dimensional surfaces \( \Sigma_1 \) and \( \Sigma_2 \), such that, for sufficiently small \( |\mu| \), we have the following.

(i) The system (3) has a unique 2-fold 1-periodic orbit near \( \Gamma \) if and only if \( \mu \in \Sigma_1 \).

(ii) The system (3) has no 1-homoclinic orbit and 1-periodic orbit near \( \Gamma \) if and only if \( \mu \) satisfies \( M_1 \mu > \beta_1(\mu) \).

(iii) The system (3) has exactly two 1-periodic orbits near \( \Gamma \) if and only if \( \mu \) satisfies \( \beta_2(\mu) < M_1 \mu < \beta_1(\mu) \).

(iv) The system (3) has exactly a 1-homoclinic orbit and a 1-periodic orbit near \( \Gamma \) if and only if \( \mu \in \Sigma_2 \).

(v) The system (3) has exactly a unique 1-periodic orbit near \( \Gamma \) if and only if \( \mu \) satisfies \( M_1 \mu < \beta_2(\mu) \).

Proof. Through taking a proper scale transformation, such as \( s = |\mu|^2 \), we can treat \( s \) as a small parameter in (28). According to \( M_1 \neq 0 \) and the implicit equation theorem, near \( \mu = 0 \), (28) can define a \((l - 1)\)-dimensional surface \( \Sigma_2(s) \), such that if \( \mu \in \Sigma_2 := \Sigma_2(0) \), (28) has exactly two negative small solutions \( s_1 = 0 \) and \( s_2 = (\omega_{12})^{1/\alpha(\mu)} + \text{h.o.t.} > 0 \).

If \( -1 < M_1 \mu < \beta_2(\mu) \), then (28) has exactly a unique negative small solution \( s_1 > 0 \). If \( M_1 \mu = \beta_2(\mu) \), then \( (\mu) \) has no negative small solution.

If \( M_1 \mu > \beta_1(\mu) \), then (28) has exactly two negative small solutions \( s_1 > 0 \) and \( s_2 > 0 \), moreover, \( s_1 \neq s_2 \).

The proof is complete.

Similarly, we can define the corresponding \( \beta_1(\mu) \) and \( \beta_2(\mu) \), and the corresponding \( \Sigma_1 \) and \( \Sigma_2 \), to obtain the following theorem.

**Theorem 6.** Suppose (H1)–(H3) and (H5) are fulfilled, \( \alpha(\mu) < 0, \omega_{12} > 1 \). If \( M_1 \neq 0 \), then, in the neighborhood of \( \mu = 0 \), there exists two \((l - 1)\)-dimensional surfaces \( \Sigma_1 \) and \( \Sigma_2 \) such that for sufficiently small \( |\mu| \), the following conclusions hold.

(i) The system (3) has a unique 2-fold 1-periodic orbit near \( \Gamma \) if and only if \( \mu \in \Sigma_1 \).

(ii) The system (3) has no 1-homoclinic loop and 1-periodic orbit near \( \Gamma \) if and only if \( \mu \) satisfies \( M_1 \mu < \beta_1(\mu) \).

(iii) The system (3) has exactly two 1-periodic orbits near \( \Gamma \) if and only if \( \mu \) satisfies \( \beta_2(\mu) > M_1 \mu > \beta_1(\mu) \).

(iv) The system (3) has exactly a unique 1-homoclinic loop and 1-periodic orbit near \( \Gamma \) if and only if \( \mu \in \Sigma_2 \).

(v) The system (3) has exactly a 1-periodic orbit near \( \Gamma \) if and only if \( \mu \) satisfies \( M_1 \mu > \beta_2(\mu) \).

\( \Sigma_1 \) is called 2-fold 1-periodic orbit bifurcation surface, \( \Sigma_2 \) is called 1-homoclinic loop bifurcation surface Figure 2.
Now, we consider the nonexistence of \( k \)-homoclinic loop and \( k \)-periodic orbit, where \( k > 1 \). We may assume that \( k = 2 \).

We rewrite the time from \( q_0 \) and \( q_1 \) as \( s_1 = e^{-\lambda t} \). Suppose \( F_2(q_2) = q_3 \), \( F_1(q_3) = q_4 = q_0 \), let \( t_2 \) be the time from \( q_2 \) to \( q_3 \), \( s_2 = e^{-\lambda t_2} \). Similar to the previous discussion, we can get its associated successor function \( G^2 = (G_1^1, G_2^1, G_1^2, G_2^2) \) as follows:

\[
G_1^1 = \delta \left( w_{12}^{-1} s_1 \right) - s_2 + M_1 \mu + h.o.t.,
\]
\[
G_1^2 = u_1 - \delta_\mu + (w_{11} w_{23} w_{21}^{-1} - w_{13}) w_{12}^{-1} s_1 + M_1 \mu + h.o.t.,
\]
\[
G_2^1 = -v_2 + \delta_\mu + w_{12} \delta s_2 + w_{44} s_1^2 \mu + M_4 \mu + h.o.t.,
\]
\[
G_2^2 = u_3 - \delta_\mu + (w_{11} w_{23} w_{21}^{-1} - w_{13}) w_{12}^{-1} s_2 + M_4 \mu + h.o.t.,
\]
\[
\delta^{-1} M_4 \mu = \mu^* (\mu) := (-w_{14})^{1/\alpha(\mu)} \left[ 1 + (1 + \alpha(\mu))^{-2(2/\alpha(\mu))} \right] + h.o.t. \tag{39}
\]

Obviously, the necessary condition that \( \delta \) has solutions is \( \Delta = -1 \) and \( (1 + w_{12}) \alpha(\mu) > 0 \), that is, \( \Gamma \) is twisted. At present, \( s_2 \) satisfies \( 0 < s_2 < \delta^{-1} M_1 \mu \ll 1 \). Substituting \( \delta \) into \( \delta^{-1} M_1 \mu = \mu^* (\mu) \),

\[
(1 + \alpha(\mu))^2 \left( s_2^{1+\alpha(\mu)} + \delta^{-1} w_{12} M_1 \mu \right)^{\alpha(\mu)} \frac{\alpha(\mu)}{s_2^{1+\alpha(\mu)}} = (w_{12})^{2+\alpha(\mu)} + h.o.t. \tag{37}
\]

Thus, we can get

\[
s_2 = \left[ -\frac{w_{12}}{(1 + \alpha(\mu))} \right]^{1/\alpha(\mu)} + h.o.t. \tag{38}
\]

Let \( N(s_2) \) and \( V(s_2) \) be the left and right of the above formula, respectively, then \( N(s_2) \) and \( V(s_2) \) are tangent at some point if and only if \( (36) \) and the following formulas are fulfilled.

\[
(1 + \alpha(\mu))^2 \left( s_2^{1+\alpha(\mu)} + \delta^{-1} w_{12} M_1 \mu \right)^{\alpha(\mu)} \frac{\alpha(\mu)}{s_2^{1+\alpha(\mu)}} = (w_{12})^{2+\alpha(\mu)} + h.o.t. \tag{37}
\]

Thus, we can get

\[
s_2 = \left[ -\frac{w_{12}}{(1 + \alpha(\mu))} \right]^{1/\alpha(\mu)} + h.o.t. \tag{38}
\]

Suppose the surface defined by \( (38) \) is \( \delta^{-1} M_1 \mu = \mu^* (\mu) \). We notice that every 1-periodic orbit also corresponds to a solution \( s_1 = s_2 > 0 \) of \( (32) \). Thus, we have the following theorem.

**Theorem 7.** Suppose \( (H1) \sim (H3) \) and \( (H5) \) are fulfilled, if \( \Delta = 1 \), then system \( (3) \) has no any \( k \)-homoclinic loop and \( k \)-periodic orbit in the small neighborhood of \( \Gamma \) for \( |\mu| \) sufficiently small.

**7. Stability**

Now, we consider the stability of homoclinic loop \( \Gamma \).

According to \( F(q_2) = F(q_3) = F(q_4) = F(q_0) \), we can get the following by \( (19) \)

\[
n_{2,1} = w_{12} \delta s^{\rho_1/\lambda_1} + h.o.t.,
\]
\[
n_{2,3} = u_1 - \delta u + (w_{11} w_{23} w_{21}^{-1} - w_{13}) w_{12}^{-1} s^{\rho_1/\lambda_1} + h.o.t.,
\]
\[
n_{2,4} = w_{44} s^{\beta_0(\mu)/\lambda_1} + h.o.t. \tag{40}
\]

By \( (17) \), we get

\[
s = \delta^{-1} x_0, u_1 = s^{\beta_0(\mu)/\lambda_1} x_0, \]

substituting into \( (40) \), we get

\[
n_{2,1} = w_{12} \delta x_0^{\rho_1/\lambda_1} x_0 + h.o.t.,
\]
\[
n_{2,3} = s^{\beta_0(\mu)/\lambda_1} x_0 - \delta x + (w_{11} w_{23} w_{21}^{-1} - w_{13}) w_{12}^{-1} s^{\rho_1/\lambda_1} + h.o.t.,
\]
\[
n_{2,4} = w_{44} s^{\beta_0(\mu)/\lambda_1} x_0 + h.o.t. \tag{41}
\]
According to (11), we know $\sigma = n_{0,1}$, $u_0 = w_{33}n_{0,3}$, and $v_0 = O(n_{0,2})$. $x_2 = n_{2,1}$, $u_2 = w_{33}n_{2,3}$, and $v_2 = O(n_{2,4})$. And by $\Re e \sigma(-B_2(0)) < 0$, $\Re e B_2(0) > 0$, we can get $\sigma_2 = O(s^{0.5}(t)\eta_0) \gg u_0$, $v_2 = O(s^{0.5}(t)/\sigma_0) \ll v_0$. Meanwhile, we make Poincaré map $F$ restrict at the half transversal section $S_{\gamma}^\delta = \{(x, y, u, v) \in S_0, 0 \leq x < \delta_1 < \delta, 0 \leq x \leq \gamma, \delta, u = 0, v = 0\}$ maps to the segment $L' = \{0 \leq x \leq y_0\}$, approximately, where $y_0$ is the shrinkage (expansion) rate. So, when $\sigma_1/\gamma_1 > 1(<1)$, we can get $y = w_1(\delta y_0)^{1/\delta} - 1 < 1(>1)$ for $\delta < 1/\sigma < 1$. Hence, we have the following.

**Lemma 11.** $\sigma_1 = \sigma_2$. Then, the homoclinic orbit $\Gamma$ is weak stable, and $\Gamma$ has a $(m + 1)$-dimensional stable manifold and a $n$-dimensional unstable manifold. If $\sigma_1/\gamma_1 < 1$, the homoclinic loop $\Gamma$ is weak unstable, and $\Gamma$ has a $(m + 1)$-dimensional stable manifold and a $(n + 1)$-dimensional unstable manifold.

If $\gamma = 0$ and $\gamma_1 = \gamma_1$, similar to above, we can get $y = w_1(\delta y_0)^{1/\delta} - 1$ not difficult. Thus, we have the following.

**Theorem 9.** If $w_1^{-1} < 1$, the homoclinic loop $\Gamma$ is weak stable, and $\Gamma$ has a $(m + 1)$-dimensional stable manifold and a $n$-dimensional unstable manifold. If $w_1^{-1} > 1$, the homoclinic loop $\Gamma$ is weak unstable, and $\Gamma$ has a $(m + 1)$-dimensional stable manifold and a $(n + 1)$-dimensional unstable manifold.

Besides, by the above discussion, we can get the following.

**Theorem 10.** The homoclinic loop or the periodic orbit of the perturbed system has the same stability with the homoclinic loop of the unperturbed system.

**8. Example**

Now, suppose the $C^r$ system (3) is 2-dimensional, $z = (x, y) \in R^2$, $r \geq 5$. We consider the stability of the homoclinic orbit $\Gamma$ under the resonance case. Denote $f(z) = f_1(x, y) + f_2(x, y)$, $\sigma = \exp\left(\int_{-\gamma}^{\gamma} (\partial f_1/\partial x + \partial f_2/\partial y)(r(t))dt\right)$, $\bar{\sigma} = \exp\left(\int_{-\gamma}^{\gamma} (\partial f_1/\partial x + \partial f_2/\partial y)(r(t))dt\right)$, We have the following two lemmas.

**Lemma 11.** $\bar{\sigma}$ is convergent, and $\bar{\sigma} = \bar{\sigma}$.

**Proof.** In fact, from [1–3], there always exist a $C^r$ transformation coordinates, such that the system (3) has the following form in a small neighborhood of the origin:

$$\begin{align*}
\dot{x} &= \lambda x + x^2 y H_1(x, y), \\
\dot{y} &= -\lambda y + xy^2 H_2(x, y),
\end{align*}$$

where $H_1(x, y), H_2(x, y) \in C^r$. So, in $U$, we have $\Gamma \cap W_{+}^u = \{(x, y) : x = 0\}$. Thus, in $U$, if $\sigma = 0$, then $\sigma = 0$. The proof is complete.

**Remark 12.** Because the divergence integration is the invariant under the $C^r$ transformation (refer [4, 16]), so the function $f(t)$ and $r(t)$ of the divergence integration $\sigma$ can be thought of the original forms of (3).

**Lemma 13.** $w_1 = 1, w_1 = 1/\sigma$.

**Proof.** According to $r(T) = (0, -\lambda \delta)$, $r(-T) = (\lambda \delta, 0)$, we get $\delta(T) = -r(-T)/r(T) = (-1, 0)$, $\sigma = 1$. And by the Liouville formula, we have $\|\sigma\| = \|w_1/\sigma_1\|$, therefore, $\sigma = 1$. And by $w_1 = 1$, $\sigma = 1$.

**Theorem 14.** If $\sigma < 1$, the homoclinic orbit $\Gamma$ is stable; if $\sigma > 1$, the homoclinic orbit $\Gamma$ is unstable.

**Conflict of Interests**

The authors declare that there is no conflict of interests regarding the publication of this paper.
