**Abstract**

**Background:** The *Trypanosoma cruzi* infection is associated with severe T cell unresponsiveness to antigens and mitogens characterized by decreased IL-2 synthesis. *Trypanosoma cruzi* mucin (Tc Muc) has been implicated in this phenomenon. These molecules contain a unique type of glycosylation consisting of several sialylated O-glycans linked to the protein backbone via N-acetylglucosamine residues.

**Methodology/Principal Findings:** In this study, we evaluated the ability of Tc Muc to modulate the activation of CD4+ T cells. Our data show that cross-linking of CD3 on naïve CD4+ T cells in the presence of Tc Muc resulted in the inhibition of both cytokine secretion and proliferation. We further show that the sialylated O-Linked Gycan residues from tc mucin potentiate the suppression of T cell response by inducing G1-phase cell cycle arrest associated with upregulation of mitogen inhibitor p27kip1. These inhibitory effects cannot be reversed by the addition of exogenous IL-2, rendering CD4+ T cells anergic when activated by TCR triggering. Additionally, in vivo administration of Tc Muc during *T. cruzi* infection enhanced parasitemia and aggravated heart damage. Analysis of recall responses during infection showed lower frequencies of IFN-γ producing CD4+ T cells in the spleen of Tc Muc treated mice, compared to untreated controls.

**Conclusions/Significance:** Our results indicate that Tc Muc mediates inhibitory effects on CD4+ T expansion and cytokine production, by blocking cell cycle progression in the G1 phase. We propose that the sialyl motif of Tc Muc is able to interact with sialic acid-binding Ig-like lectins (Siglecs) on CD4+ T cells, which may allow the parasite to modulate the immune system.

**Introduction**

Chagas disease is caused by the protozoan parasite *Trypanosoma cruzi* and is an important endemic infection in Latin America. Lately, it has also become a health concern in the United States, Canada and Europe [1,2]. The parasite is transmitted via the faeces of insect vectors of the family Reduviidae [3]. When the parasite enters the host it evokes a strong immunological response that is able to control the parasitic multiplication but not eliminate it [4–6]. After a delay that can be as much as 20 years, about a third of infected patients enter the chronic phase, characterized by the symptoms of Chagas disease [7] It is not yet clear how the observed pathology is triggered, but there is considerable evidence that persistence of the parasite is associated with a chronic inflammatory response, a major cause of Chagas disease [8–13].

* T. cruzi employs a variety of strategies to evade the immune system and maintain itself in the infected host. The main method involves inhibiting specific T-cell responses so that it frequently establishes chronic infections [12–19]. A number of both host-dependent and parasite-induced mechanisms accomplish this immune regulation [20]. The T cells of infected hosts are largely unresponsive to antigens and mitogens, and this results in reduced IL-2 synthesis and increased nitric oxide (NO) production. Although spleen cell responses to ConA were more apparent in infected IFN-γR−/− or inducible nitric oxide synthase
(iNOS)-deficient mice than in their control littermates, IL-2 production remained as strongly affected [14].

It is thought that the large number of O-glycosylated Thr/Ser/Pro-rich mucin molecules (Tc Muc) on the surface of T. cruzi are the main acceptors of sialic acid and are shown to be responsible for most of the immune effects of infection [14–16], [21–26]. T. cruzi cannot synthesize sialic acid but it produces a surface trans-sialidase that transfers sialic acid from the sialglycoconjugates of the host to the parasite glycoconjugates, especially to terminal β-galactosyl residues of Tc Muc [27–30]. Sialylated glycoconjugates are believed to play a role in a number of host-parasite interactions, such macrophage attachment, avoidance of complement lysis, and alteration of host immune responses [28], [31–36].

T. cruzi mucin has been shown to inhibit T cell proliferation as well as IL-2 production and transcription in response to mitogens and to anti-CD3. This effect involves action at the transcriptional level, since Tc Muc inhibits transcription driven from the IL-2 promoter [15,16]. Moreover, transcription of reporter genes under the control of CD28RE, NFAT and AP-1, but not of NF-kB sites, is also inhibited by Tc Muc to different extents, with the greatest effect being on NFAT. In agreement with this, overexpressing NFAT markedly reduced Tc Muc inhibition of IL-2 transcription. Tc Muc also inhibits early events in T cell activation such as tyrosine phosphorylation of the adapter protein SLP-76 and the tyrosine kinase ZAP-70 [14].

Although sialylated glycoconjugates play important roles in the initiation, persistence, and pathogenesis of Chagas’ disease, their precise roles and their host receptors remain unknown. There is evidence that sialylated Tc Muc can interact with Siglec-E (CD33), a member of the Siglec family of sialic acid-binding Ig-like lectins found mainly on cells of the immune system [33,37]. Siglecs have immunoreceptor tyrosine-based inhibitory motifs (ITIMs) in their cytosolic tails, which suggests that they are able to perform inhibitory function when they bind sialylated carbohydrates [30–40]. Siglec-E is a restricted leukocyte antigen mainly expressed on mouse phagocytic cells and on antigen-presenting cells (APCs) including macrophages and dendritic cells [41,42]. The binding of pathogenic T. cruzi to Siglec-E-expressing cells is followed by rapid mobilization of Siglec-E into the contact zone between parasite and host cells. It appears that binding of Siglec-E affects the activity of APCs, leading to lower production of IL-12, which is important for Th1 responses [33,37].

The present study shows that cross-linking of CD3 on naive CD4+ T cells in the presence of Tc Muc resulted in the inhibition of both cytokine secretion and lymphoproliferative response as compared to the controls obtained upon TCR triggering. The T. cruzi mucin-induced suppression of CD4+ T cell response is mediated by G1 cell cycle arrest and is associated with up-regulation of the cyclin-dependent kinase inhibitors p21Waf1. Interestingly, in vivo administration of Tc Muc during murine experimental infection with Trypanosoma cruzi parasites rendered lower frequencies of splenic IFN-γ producing CD4+ T cells in the host compared to infected controls. These effects were accompanied by a greater susceptibility to infection, as shown by higher levels of parasitemia in infected mice treated with Tc Muc compared to non-treated infected controls. In the present work, we support evidence that sialylated O-Linked Glycan residues of Tc Muc exert inhibitory effects on CD4+ T cells through the interaction of the sialyl motif with the sialic acid-binding Ig-like lectin host receptors (Siglecs). We propose that signaling of CD4+ T cells via Siglecs is at least in part responsible for the induction of T cell anergy, and that this may allow the parasite to interfere with the host immune system.

Materials and Methods

Ethics Statement

This work was approved by the Research Ethics Committee of Fiocruz (protocol CEUA-LW8/10). Protocols for animal studies were approved by the Institutional Ethical Committees in accordance with international guidelines. All animal experimentation was performed in accordance with the terms of the Brazilian guidelines for the animal welfare regulations.

Preparation of Sialoglycoproteins from T. cruzi DM28c Strain

Sialoglycoproteins from T. cruzi DM28c were obtained as described [Agrells et al., 2003]. Epimastigote forms were grown in 1 l of brain heart infusion medium containing 10% fetal calf serum, and supplemented with 10 mg/l hemin and 20 mg/l folic acid. Cultures were incubated at 28°C with shaking (100 rpm) for 5–7 days. Cells were harvested by centrifugation, washed three times with 0.9% NaCl and frozen at −20°C. Frozen cells were thawed, extracted with cold water and the pellet recovered by centrifugation for three times. The pellet was, than extracted with 45% (v/v) aqueous phenol at 75°C. The aqueous phase of the phenol extract was dialyzed, lyophilized, redissolved in water, and applied into a Bio-Gel P-60 column. Carbohydrate-containing material in the excluded volume was lyophilized and suspend in chloroform/methanol/water (10:10:3, v/v). The glycoproteins in this solvent mixture were hydrolyzed and applied into an octyl-sepharose column and eluted with 60% (v/v) propanol in water. The mucin obtained were analyzed by sodium dodecyl sulphate (SDS)-polyacrylamide gel electrophoresis and stained with periodic acid/Schiff’s reagents for carbohydrate detection. In order to obtain a lipopolysaccharide (LPS)-free preparation the sialoglycoproteins obtained were passed through an agarose-immobilized polynynxin B column (Sigma Chemical Co., MO). For desialylation reaction, purified mucin was subjected to treatment with 0.2 U/ml of Vibrio cholerae neuraminidase, in PBS pH 6.0 containing 1 mM CaCl2. After incubation at 37°C for 1 h, the enzyme was heat-inactivated and the solution was applied into an octyl-sepharose column. The desialylated mucin was eluted with 60% (v/v) propanol in water. The eluted sample was dried by rotary evaporation, resuspended in water and lyophilized.

Animals, Infection and In vivo Tc Muc Treatment

Male BALB/c mice, aged 6–8 weeks, were obtained from the Oswaldo Cruz Foundation animal facility. Epimastigotes of T. cruzi DM28c clone were cultured at 27°C in BactoTM Brain Heart Infusion (BHI, Becton Dickinson Company, USA) supplemented 10 μg/mL hemin, 0.02 g/L folic acid (both from Sigma-Aldrich, USA) and 10% of heat inactivated fetal bovine serum (FCS, Gibco/Lifetechnologies). Acute infection was performed by inoculating the animals intraperitoneally with 2×107 chemically induced metacyclic forms of Trypansoma cruzi Dm28c clone obtained as described [43]. T. cruzi mucin diluted in PBS was administered via I.P. at 20 μg/mouse and on alternate days starting at day of infection until day 22 after infection and sacrificed on day 24. A control group was treated with PBS using the same regimen. Parasitemia was monitored on days 7, 9, 11, 13, 15, 18, 20 and 22 post infection in blood obtained from tail vein and lysed in Tris-buffered ammonium chloride by counting trypomastigotes forms. Mice were killed during the acute phase, at 24 days post infection.
T Cell Purification and in vitro Proliferation

Primary T-cell-enriched populations from naïve mice were obtained by nylon wool filtration of unfractionated splenic cell suspensions previously depleted of erythrocytes by treatment with Tris-buffered ammonium chloride. Highly purified CD4+ T cells were nonadherent cell treated with anti-CD8, anti-B220, anti-MHC class II, anti-MAC-1, anti-β2TCR (all at 10 μg/mL, BD Pharmingen™) and purified with anti-IgG-coated magnetic beads (Biomag perseptive Biosystems). CD4+ T cells were cultured in DMEM supplemented with 2 mM glutamine, 5 × 10^{-5} M 2-ME, 10 μg/mL gentamicin, 1 mM sodium pyruvate, and 0.1 mM MEM nonessential amino acids (all from Gibco™, Invitrogen Corporation) plus 1% Nutridoma-SP (Roche, Germany) instead of FBS. For proliferation assays, CD4+ T cells (3 × 10^5 cells/well) were re-suspended in complete culture medium containing 1% Nutridoma and were stimulated with plate bound anti-CD3 mAb (5 μg/mL, clone 145-2C11, BD Pharmingen), with or without T. cruzi mucin or control mucin derived from bovine submaxillary glands was used, nor was it reverted by addition of exogenous IL-2 when naïve splenic purified CD4+ T cells were stimulated with pre-coated anti-CD3 for 72 hr. Results are the means ± SE of triplicate cultures of three different experiments. *Differences between Tc mucin treatment versus anti-CD3 stimulated positive control are significant (P<0.05).

doi:10.1371/journal.pone.0077568.g001

Figure 1. Tc Muc inhibits CD4+ T cell proliferation. (A) Purified CD4+ T cells from naïve spleens were stimulated with pre-coated anti-CD3 for 72 hr, in the presence or absence of increasing concentrations of Tc Muc (10, 20 and 50 μg/mL). Proliferation was measured 72 hr after stimulation by [3H]thymidine incorporation. (B) The inhibition of proliferation by Tc mucin was not observed when control mucin derived from bovine submaxillary glands was used, nor was it reverted by addition of exogenous IL-2 when naïve splenic purified CD4+ T cells were stimulated with pre-coated anti-CD3 for 72 hr. Results are the means ± SE of triplicate cultures of three different experiments. *Differences between Tc mucin treatment versus anti-CD3 stimulated positive control are significant (P<0.05).
Detection of Intracellular Cytokine by Flow Cytometer

Fresh spleen cells were harvested from non-infected or from infected mice at 8 or 15 days post infection (DPI). Cells were washed in PBS (containing 2% fetal bovine serum) and incubated for 30 min at 4°C with anti-CD16/CD32 for Fc\'b blocking. For phenotypic analysis of T cells by FCM, we performed three-color labeling for 30 min at 4°C, using allopheyococyanin (APC)-labeled anti-CD4 and fluorescein isothiocyanate (FITC)-labeled anti-CD8 monoclonal antibodies, followed by phycoerythrin (PE)-labeled antibody anti-CD69. All monoclonal antibodies (mAbs) used in FCM were from BD Pharmingen\textsuperscript{TM}. Cells were washed and resuspended in PBS supplemented with 2% fetal bovine serum, and data were acquired on a FACSCalibur system (BD Biosciences). Analyses were done after recording 25,000–50,000 events for each sample, using a CELLQuest software (BD Biosciences). To determine the number of IFN-\(\gamma\)-producing T cells in the infected spleen, intracellular cytokine staining was performed. Single cell suspension of infected spleen was prepared, and 10\(^6\) cells/well were cultured in 96-well U-bottom plates. Cells were left untreated or polyclonal stimulated with PMA (20 ng/ml) and ionomycin (500 ng/ml) for 3 h at 37°C in 5% CO\(_2\). Brefeldin A (10 \(\mu\)g/ml) was added to the culture for the intracellular cytokine accumulation. Cell surface marker and intracellular cytokine staining for IFN-\(\gamma\) was performed using a Cytofix/Cytoperm kit (BD Pharmingen). All samples were collected with a FACScalibur and were analyzed with Summit 4.3 2 software (Dako).

Assessment of Cell-cycle Arrest and Western Blotting Analysis

Purified CD4\(^+\) T cells (2\(\times\)10\(^6\) cells/well, 1 mL) were cultured in 24 well plates, stimulated or not with plate bound anti-CD3 (3 \(\mu\)g/ml), in the presence or absence of TcMuc or desialylated TcMuc (20 \(\mu\)g/ml) for 3 days at 37°C and 7% CO\(_2\) in a humid atmosphere. At the end of incubation period, cells were fixed with 70% ethanol and stained with propidium iodide (PI, 20 \(\mu\)g/ml, BD Immunocytometry Systems, USA) in PBS containing 0.1% Triton-X-100 and RNase (10 \(\mu\)g/ml) for 15 min. Data was acquired on a BD FACS Calibur flow cytometer using CellQuest software (BD Immunocytometry Systems, USA). For analysis of the cyclin D3 and p27 expression, cells were alternatively harvested after 3 days of stimulation and lysed in RIPA lysis buffer. Lysates were centrifuged at 16,000g for 10 min at 4°C and the proteins present in the supernatants were solubilized in a SDS sample buffer for electrophoresis by boiling for 5 min and fractionated in SDS-PAGE 9%. The proteins were transferred to PVDF membranes (Trans-Blot system, Bio-Rad) and the membranes were incubated overnight with anti-cyclin D3, anti-p27 and anti-actin (Cell Signaling Technology, Inc.), followed by horseradish peroxidase (HRP)-conjugated anti-mouse secondary antibodies IgG for ECL quinolinescence reaction (Amersham-Pharmacia).

Tissue Preparation and Histochemistry

Heart tissues were harvested 24 days after 

\begin{equation}
\text{Tissue preparation and histochemistry}
\end{equation}

Heart tissues were harvested 24 days after *T. cruzi* infection into BALB/c mice. Tissues were fixed in 10% neutral buffered formalin, dehydrated, and paraffin embedded. Sections (4 \(\mu\)m) were obtained and stained with hematoxylin-eosine for topographical analyses of heart tissues. Sections were analyzed under light microscopy. Positive identification of leukocyte infiltration was determined by matching nuclear morphology and cytoplasmic color. Inflammatory score present in the tissue were determined in 40 sequential sections per mouse. Statistical differences between mean values were evaluated by ANOVA, and pairwise comparisons were done by the Tukey test.
Statistical Analysis
Statistical analyses were performed with GraphPad Prism 4 software, using one-way ANOVA test. Results were expressed as mean ± standard error (S.E.), Differences between control and treated group were considered statistically significant when \( P \leq 0.05 \).

Results
Tc Muc Supresses CD4\(^+\) T Cell Proliferation
To evaluate the effect of Tc mucin on in vitro CD4\(^+\) T cell activation and proliferation, equal numbers of purified CD4\(^+\) T cells isolated from naive mice were stimulated by plate bound anti-CD3 mAb in the presence or absence of graded doses of Tc Muc.

Figure 3. Tc mucin inhibits cytokine production upon TCR stimulation. Purified CD4\(^+\) T cells from naïve spleens were stimulated with plate bound anti-CD3 (5 \( \mu \)g/mL), in the presence or absence of Tc Muc (20 \( \mu \)g/mL). Cytokines IL-2, IL-4, IL-10, IFN-\( \gamma \), TNF-\( \alpha \) and TGF-\( \beta \) were detected by ELISA in the supernatants obtained after 48 h stimulation. All cytokine values in the presence of Tc Muc were significantly lower than controls (\( P \leq 0.05 \)). Results are the means ± SD of triplicate cultures of three different experiments.

doi:10.1371/journal.pone.0077568.g003
Our results indicated a significant inhibition of CD4+ T cell proliferative response in a dose-responsive manner by Tc Muc, with a marked inhibition after 20 μg/mL (Figure 1a). However, in the control culture, the CD4+ T cell population retained the ability to respond to plate-bound anti-CD3 mAb, indicating that these cells were fully capable of transmitting activation signals, leading to cell proliferation through the TCR/CD3 receptor (Figures 1a and b). Similar results showing the inhibitory effect of Tc Muc on CD4+ T cell activation were obtained upon stimulation by plastic-absorbed anti-CD3 mAb (Figure S1).

To determine whether the addition of IL-2 is able to overcome the inhibitory effect of Tc Muc, CD4+ T cells were stimulated with plate-bound anti-CD3 mAb and cultured for 72 hr in the presence of Tc Muc and recombinant IL-2 (rIL-2). In these conditions, rIL-2 could not prevent the responsiveness of CD4+ T cell to TCR-mediated T cell activation induced by Tc Muc (Figure 1b). However, our results indicate that alterations in the patterns of mucin O-glycosylation have a possible influence on the inhibitory effect mediated by Tc Muc on CD4+ T cells, as this phenomenon was not observed when murine naive CD4+ T cells were cultivated under similar conditions with bovine submaxillary gland mucin (Figure 1b). Furthermore, we showed that when restimulated with anti-CD3, activated CD4+ T cells cultured in the presence of Tc Muc were not able to respond to the polyclonal stimulus, indicating that the effect of Tc mucin on T cell mitogen responses bypasses the early receptor signaling of T cell activation (Figure 2).

**Tc Muc Downmodulates Cytokine Expression**

Our data showing that Tc Muc promotes unresponsiveness of CD4+ T cells upon mitogen activation led us to investigate the cytokine profile of these cells. To address this question, purified CD4+ T cells from naive spleens were stimulated with plate-bound anti-CD3 for 72 hr, in the presence or absence of increasing concentrations of native or desialylated Tc Muc (10 and 20 μg/mL). Proliferation was measured 72 hr after stimulation by [3H]thymidine incorporation. *Differences between native or desialylated Tc Muc treatment versus anti-CD3 stimulated positive controls are significant (P<0.05).* 

The inhibition of proliferation by Tc Muc was partially recovered when T. cruzi mucin was desialylated by previous treatment with neuraminidase (P=0.0022). Results are the means ±SE of triplicate cultures. This experiment was repeated three times, with similar results each time.

doi:10.1371/journal.pone.0077568.g004

Our results indicated a significant inhibition of CD4+ T cell proliferative response in a dose-responsive manner by Tc Muc, with a marked inhibition after 20 μg/mL (Figure 1a). However, in the control culture, the CD4+ T cell population retained the ability to respond to plate bound anti-CD3 mAb, indicating that these cells were fully capable of transmitting activation signals, leading to cell proliferation through the TCR/CD3 receptor (Figures 1a and b). Similar results showing the inhibitory effect of Tc Muc on CD4+ T cell activation were obtained upon stimulation by plastic-absorbed anti-CD3 mAb (Figure S1).

To determine whether the addition of IL-2 is able to overcome the inhibitory effect of Tc Muc, CD4+ T cells were stimulated with plate-bound anti-CD3 mAb and cultured for 72 hr in the presence of Tc Muc and recombinant IL-2 (rIL-2). In these conditions, rIL-2 could not prevent the responsiveness of CD4+ T cell to TCR-mediated T cell activation induced by Tc Muc (Figure 1b).

However, our results indicate that alterations in the patterns of mucin O-glycosylation have a possible influence on the inhibitory effect mediated by Tc Muc on CD4+ T cells, as this phenomenon was not observed when murine naive CD4+ T cells were cultivated under similar conditions with bovine submaxillary gland mucin (Figure 1b). Furthermore, we showed that when restimulated with anti-CD3, activated CD4+ T cells cultured in the presence of Tc Muc were not able to respond to the polyclonal stimulus, indicating that the effect of Tc mucin on T cell mitogen responses bypasses the early receptor signaling of T cell activation (Figure 2).

**Tc Muc Downmodulates Cytokine Expression**

Our data showing that Tc Muc promotes unresponsiveness of CD4+ T cells upon mitogen activation led us to investigate the cytokine profile of these cells. To address this question, purified CD4+ T cells isolated from naive mice were stimulated with plate-bound anti-CD3 mAb in the presence or absence of Tc Muc for 2 days, then the supernatants were collected and tested for the cytokines IFN-γ, TNF-α, IL-2, IL-4, IL-10 and TGF-β. Our results demonstrate that, at day 3, Tc mucin treatment of activated cells resulted in a significant decrease in all the cytokines analysed when compared to the anti-CD3 stimulated positive control (Figure 3). The suppressive effect of Tc Muc on CD4+ T cell activation and expansion in vitro is not correlated with any possible effect of the mucin on the death induction of CD4+ T cells, since viability was not significantly affected after 3 days in culture as evaluated by MTT cell viability assay (Figure S2).

**Inhibition of CD4+ T Cell Proliferation is Partially Reverted upon Neuraminidase-treatment of T. cruzi mucin and is Associated to Upregulation of p27Kip1**

The sialic acid residues are incorporated into Tc Muc (Figure S3 and S4) in a reaction catalyzed by the parasite *trans*-sialidase [27–30]. This sialylation influences the effectiveness of the inhibitory properties of Tc Muc on dendritic cell function through the interaction with the sialic acid-binding Ig-like lectins that are predominantly expressed on cells of the immune system [33,37]. We next investigated the role of terminal sialic acid in CD4+ T cell activation. For this purpose, Tc Muc was subjected to treatment with 0.2 U/mL of *V. cholerae* neuraminidase to remove the sialic acid terminal residues. To this end, purified CD4+ T cells from naive spleen were stimulated with plate-bound anti-CD3 for 72 hr, in the presence or absence of increasing concentrations of native or desialylated Tc Muc (10 and 20 μg/mL), and proliferation was measured 72 hr after stimulation as [3H]thymidine incorporation.

Our findings demonstrated that the inhibition of proliferation by Tc Muc was partially reverted when T. cruzi mucin was desialylated by previous treatment with neuraminidase, indicating a possible role for the sialic acid-binding Ig-like lectins’ receptors in the inhibitory effects on CD4+ T cells (Figure 4).

While several mechanisms are known to interfere with cell proliferation, they act in different cell cycle phases. We decided to analyze the effects of Tc Muc in specific cell cycle phases. Purified CD4+ T cells from naive spleens were stimulated with plate-bound anti-CD3 in the presence or absence of native T. cruzi mucins (20 μg/mL) for 72 hr and stained with the chromatin intercalating dye propidium iodide (PI) after nuclease digestion for analysis of the cell cycle by flow cytometry. Our data revealed 14% of CD4+ T cells in the M phase of the cell cycle when they were activated with anti-CD3 in the presence of Tc Muc, as compared with 42% of positive control cells activated with anti-CD3 only. This remarkable decrease was partially reverted upon neuraminidase treatment, as our findings indicate 33% of CD4+ T cells in M phase of the cell cycle when the cells were treated with desialylated Tc Muc during activation with anti-CD3 (Figure 3). Further, an inverse correlation was found with the population of cells in the G1 phase, as we observed 45% of CD4+ T cells were in G1 phase of the cell cycle when they were activated with anti-CD3 in the presence of Tc Muc, as compared with 19% of positive control cells activated with anti-CD3 only. This remarkable decrease was partially reverted upon neuraminidase treatment, as our findings indicate 33% of CD4+ T cells in M phase of the cell cycle when the cells were treated with desialylated Tc Muc during activation with anti-CD3 (Figure 3). Further, an inverse correlation was found with the population of cells in the G1 phase, as we observed 45% of CD4+ T cells were in G1 phase of the cell cycle when they were activated with anti-CD3 in the presence of Tc Muc, as compared with 19% of positive control cells activated with anti-CD3 only. Activation of CD4+ T cells in the presence of desialylated Tc Muc yielded 33% of the cells in G1 phase, showing a significant decrease (P<0.005) of the cells in this phase as compared to the controls activated in the presence of the native Tc Muc (Figure 3). These results indicate that Tc Muc inhibits cell proliferation by the induction of cell cycle arrest in G1 phase.

We next investigated the effects of Tc Muc on G1 cell cycle regulators, specifically cyclin D3 and the mitogen repressor p27Kip1 [45–47]. To evaluate the Tc Muc inhibitory effect on T lymphocyte activation, CD4+ T cells isolated from naive mice were stimulated with plate bound anti-CD3 mAb in the presence or absence of graded doses of native or desialylated Tc Muc. As demonstrated in Figure 5, activated CD4+ T cells show a typical profile of proliferating T cells, with upregulation of cyclin D3 and down-regulation of p27Kip1 (Figure 5b). In contrast, decreased
cyclin D3 protein levels were associated with impaired TCR/CD3-triggered CD4 T cell activation in the presence of Tc Muc for 72 h. This result was correlated with elevated expression of cell cycle repressor p27Kip1. Tc mucin did not affect the actin protein levels, which persisted throughout the 72 h experiment period of the T cells’ proliferation in response to anti-CD3 (Figure 5). Most interestingly, when CD4+ T cells were treated with desialylated Tc Muc during the CD3-activation protocol, we observed a reversion of the inhibitory profile as demonstrated by the upregulation of cyclin D3 and down-modulation of p27Kip1, a profile similar to what is described for CD3-activated T cells (Figure 5b). Based on our results, we postulated that Tc Muc might show potent antiproliferative effects on CD4+ T cells, inducing G1 phase arrest, by increasing the amount of p27Kip1 beyond a putative threshold.

**Triggers of the Sialic Acid-binding Ig-like Lectin-E Receptor (Siglec-E) Induce Suppression of CD4+ T Cell**

The interaction mediated by glycoconjugates expressed on parasites and sialic acid-binding Ig-like lectin-E expressed on the host cells may account for the effects in a complex and dynamic situation at the interface between parasites and host cells. In the present work, we investigated whether the Siglec-E could mediate suppression of CD4+ T cells. To address this question, equal numbers of purified CD4+ T cells isolated from naive mice were stimulated by plastic-absorbed anti-CD3 mAbs in the presence or absence of Tc Muc anti-Siglec-E (CD33) or isotype control antibody. As we expected, CD4+ T cell population show the ability to respond to plastic-coated anti-CD3 mAbs and this expansion was abrogated when the cells were cultured in the presence of Tc Muc. Most interestingly, when CD4+ T cells were co-cultured with plastic-coated anti-CD3 mAbs together with anti-CD33 but not isotype control antibody, we observed a statistically significant abrogation of the proliferative CD4+ T cell response (Figure 6).

**Inhibition of in vivo Development of CD4+ T Cell Responses in Trypanosoma cruzi Infection**

To determine the in vivo effects of administration of Tc mucin, we injected intraperitoneally BALB/c mice with chemically induced metacyclic trypanomastigotes from T. cruzi Dm28c strain (2 × 10⁷). The data shown in Figure 7a indicate that control mice infected with TCT developed a low blood parasitemia. In contrast, infected mice treated with Tc mucin showed a precocious blood parasitemia at day 13 post-infection, which further increased (approximately 3-fold) as the infection continued. The susceptibility of the Tc treatment was correlated with augmented infiltration of leucocytes in the heart at day 21 post-infection (Figure 7b–c).

Since the protective responses against T. cruzi infection are associated with the development of IFN-γ-dependent responses, we set out to determine any difference in the levels of type-1 effector T cells. Recall assays upon polyclonal stimulation showed that IFN-γ production by splenic cells from Tc mucin-treated mice was significantly diminished (over 50%) as compared to responses elicited by experienced splenocytes isolated from infected control mice at 21 d.p.i. (Figure 8a). These findings were also correlated with reduced levels of TNF-α production by splenic cells from Tc mucin-treated mice under polyclonal stimulation, indicating that type 1 protective responses could be affected in those mice (Figure 8b). Since our findings demonstrated that the Trypanosoma cruzi sialoglycoproteins can modulate the splenic cytokine response, a matter that could be related to the enhanced parasite virulence seen in the in vivo administration of mice with Tc mucin, we next tested the hypothesis that the infection in Tc Muc-treated mice may have altered the T cell responses, thus inducing a loss of protection of parasitic load and increased signs of disease. Since the protective responses against T. cruzi infection are associated with the development of IFN-γ-dependent responses, we set out to determine whether the Trypanosoma cruzi sialoglycoproteins can modulate the T cell activation profile, a matter that could be related to the enhanced parasite virulence seen in the in vivo administration of mice with Tc mucin. Using multiparameter FACS analysis we assessed the expression of the major cell surface markers that are known to undergo changes after in vivo activation of T cells. We found that both CD4+ and CD8+ T cells from T. cruzi infected animals treated with Tc mucin express the CD69 marker at levels comparable to the infected controls (Figures 8c–d). However, recall assays upon polyclonal stimulation showed a negligible reduction of frequency of both IFN-γ secreting CD4+ T cells and CD8+ T cells from Tc mucin-treated mice in comparison with the control infected group, indicating that type 1 protective
Discussion

The relative strengths of the host immune system and pathogen virulence influence the lifespan of the infection, and pathogens have evolved many strategies to evade the immune system of the host and establish chronic infections. *T. cruzi* provides a good example of such a strategy: its surface is covered by sialic acid residues and it produces a unique enzyme, the trans-sialidase that transfers sialic acid from host glycoconjugates to mucin-like molecules on its surface [27–30]. *In vitro* studies have shown that these mucins are the most abundant glycoproteins on the surface of the parasite and that they play a key role in how the parasite invades the host and avoids its immune system [14–16], [21–23].

The sialylated mucins mask parasite antigenic determinants, so protecting the parasite from host attack by, for example, antigalactosyl antibodies and complement factor B [23], [48–50].

Interestingly, recent studies have demonstrated that in addition to masking parasite antigens, the *T. cruzi* surface sialic acid is also responsible for direct interaction with the inhibitory host cell receptor, Siglec-E [33,37]. Moreover, ligation of Siglec-E on the DC surface with cross-linking antibodies reduces the capacity of T cells to be activated and proliferate [33]. Furthermore, it has been shown that binding of Tc Muc to Siglec-9 results in a dampening of cell function and is related to the production of IL-10 [33].

Mucins derived from other organisms and species, such as mammals, can also inhibit T cell proliferative responses. In recent years, it has also been shown that the inefficient host immune response to cancer antigens is at least in part due to the presence of carcinoma-associated mucins [51–55].

In the present study, we have presented evidence that Tc mucin is able to inhibit CD4+ T cell proliferation. The suppression of T cell responses has been shown to be a result of the diminished production of IL-2 and its receptor CD25 [14–16]. In fact, we found that exposure to Tc Muc significantly diminished the level of IL-2 secretion in response to TCR activation. Moreover, our data show that the T cell anergy induced by Tc mucin was not reversed by exogenous IL-2, indicating that the IL-2 pathway is impaired when CD4+ T cells are activated in the presence of Tc Muc.

To further analyze the effects of Tc Muc treatment, we tested whether cytokine secretion was affected. According to our findings, Tc Muc was able to inhibit the production of IFN-γ, TNF-α, IL-2, IL-4, IL-10 and TGF-β cytokines by TCR-stimulated CD4+ T cells. This inhibitory property of Tc Muc may affect the course of the parasite-host interaction during the acquisition of cell-mediated adaptive immune responses, therefore damping protective host responses and so establishing persistent infections.

Our findings indicating that Tc Muc has such a strong inhibitory effect on T lymphocytes is in agreement with experiments showing that the *T. cruzi*-associated mucins have an immunosuppressive effect [14–16]. It is also consistent with clinical observations that host animals acutely infected with *T. cruzi* develop symptoms of immunosuppression, including functional alterations of lymphocytes and other cells involved in immune responses [56–64]. The sialylated ligands are strong candidates to interfere with host immunological responses, both innate and adaptive [38]. In this connection, it has been suggested that interactions involving these ligands alter leukocyte function and thereby facilitate the establishment of infection. It was shown...
Figure 8. Splenocytes from T. cruzi infected mice treated with Tc mucin produce low levels of IFN-γ. BALB/c mice were infected i.p. with $2 \times 10^5$ chemically induced metacyclic forms of Trypanosoma cruzi Dm28c clone. The mice received i.p. injections of Tc Muc (20 µg/mouse) or PBS on alternate days starting at day of infection. Non-infected mice were used as control group. Twenty four days after infection, purified splenocytes were stimulated with PMA and ionomycin, as described in the Methods section, and supernatants were harvested at 24 h for determination of (A) IFN-γ, (B) TNFα.
recently that the interaction of Siglec-9 with sialylated ligands produced by *Streptococcus* reduced neutrophil responses and increased survival of the bacteria [65]. We have used anti-Siglec E antibodies to examine whether the cross-linking of surface Siglec-E inhibits T cell proliferation. We found that Fab concentrations of up to 5 μg/ml did significantly inhibit the proliferation of stimulated T cells.

In the light of this finding, we propose that the T cell surface mucin receptor Siglec-E is implicated in the inhibition of T cell proliferation. Importantly, our results showing induction of G1 cell cycle arrest associated with up-regulation of the cyclin D inhibitor p27 further support a modulatory role of sialylated Tc Muc in signal transduction during T cell activation. The p27 is a phosphatase regulator that appears to participate in the G1 cell cycle arrest checkpoint [45–47]. The observation that desialylated Tc Muc loses its anti-mitogenic effect strengthens this notion. As the desialylated Tc Muc still contain a high content of O-linked oligosaccharides it is possible that its remaining T cell inhibitory effects after neuraminidase treatment could be due to the binding of O-glycan moieties to other host lectin receptors. Importantly, we found that exposure of mice to Tc Muc when they were being infected with *Trypanosoma cruzi* increased their susceptibility to infection as shown by increased parasitemia and heart damage at 21 dpi. At the same time we noted a lower frequency of IFN-γ producing CD4+ T cells from naïve spleens after stimulation by [3H]thymidine incorporation. *Differences (p<0.05) as determined by the Student t test.* To access the T cell activation profile CD69 expression on both CD4+ (D) and CD8+ (E) T cells were analysed by FACS analysis; the frequency of IFN-γ producing T cells from splenocytes polyclonally stimulated with PMA/ionomycin, and the percentages of both IFN-γ producing CD4+ T cells (F) and CD8+ T cells (G), were determined by intracellular cytokine FACS-staining. #Infected group are statistically different from non-infected control mice (*P<0.05). Asterisks represent statistical differences between Tc mucin treated versus non-treated mice from infected groups as determined by the Student t test (*P<0.05). All experiments were repeated at least 3 times.

**Figure S2 Measurement of T cell viability in the presence of Tc muc in a dose-dependent manner.** Total splenic T cells seeded at 100 μL/well in a flat-bottom 96-well plate (3 × 10⁶ cells/well) were cultured in DMEM supplemented with 10% FBS in the presence of various doses of Tc Muc. Cell viability was measured by adding 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT) assay at a 1/10 volume of the total cell culture volume at 18 hr of culture. After incubating for 4 hours, 0.01 N HCl with 10% sodium dodecyl sulfate was added (100 μL/well) to dissolve the formazan crystals formed by live cells, and the absorption of each well was measured by an enzyme-linked immunosorbent assay plate reader (Molecular Devices Co., Sunnyvale, CA, USA) at 540 nm. Values represent the mean ± SD absorbance of triplicate cultures. (TIF)

**Figure S3 Carbohydrate analysis and correlation spectroscopy of the T. cruzi Dm28c strain sialoglycoproteins.** Intact sialoglycoproteins were methanolized with 0.5 M HCl in methanol for 18 h at 80 °C, neutralized with silver carbonate and re-N-acetylated with acetic anhydride. The dried residue was trimethylsilylated by addition of bis(trimethylsilyl)-trifluoroacetic amide/pyridine (1:1 v/v). The products were analyzed by gas-liquid chromatography (GC) on a DB-1 fused silica column (30 m × 0.25 mm i.d.) using hydrogen as the carrier gas. The column temperature was programmed from 120 to 240°C at 2°C min⁻¹. (A) Monosaccharide analysis by GC of the trimethylsilylated methylglycosides demonstrating the presence of (1) Man; (2) Gal; (3) GlcNAc and (4) Neu5Ac in a molar ratio of 3:1.5:1:0.5. Electron impact–mass spectrum of per-O-trimethylsilylated Neu5Ac (4). Insert: 15% SDS-PAGE of sialoglycoproteins from *T. cruzi* Dm28c strain and stained with periodic acid/Schiff’s reagents for carbohydrate detection. (B) Partial 600 MHz TOCSY spectra of sialoglycoproteins purified from *T. cruzi* Dm28c strain. The spectra were obtained at 25°C, using an 80-ms mixing time. The spectral regions are numbered as follows: 1, GlcNAcβ1→NAsn H-1 trace; 2, cross-peaks arising from β-Galp residues attached to the GlcNAcα1→OThr; 3, cross-peaks arising from correlations between the Neu5Ac H-3eq and ring protons. (TIF)

**Figure S4 Effect of neuraminidase-treatment on T. cruzi mucin.** Western blot following non-reducing SDS gel electrophoresis showing the effect of incubation of Tc Muc with 0.2 U/mL of *V. cholerae* neuraminidase on Maackia amurensis (MAA) binding. MAA binding to Tc Muc corroborates the presence of sialic acid 2→3Gal (Line A). Neuraminidase treatment of Tc Muc abrogated staining by MAA (Line B). Protein load to the gel was detected by silver staining (Bottom line). Purified Tc Muc (1 μg) was electrophoresed on 10% SDS-PAGE gels and blotted onto nitrocellulose membranes. The membrane was blocked in a blocking solution (150 mM NaCl, 10 mM Tris, pH 7.5, 10% Tween 20) for 2 h at room temperature. The membranes were incubated for 1 h with 10 μg/ml biotin-labeled Maackia amurensis lectin (EY Laboratory). Membrane was washed five times and incubated with a 1:2000 dilution of anti-biotin horseradish peroxidase conjugate (Cell Signaling

**Supporting Information**

**Figure S1 Tc mucin inhibits Thy-1 triggered CD4+ T cell proliferation.** Purified CD4+ T cells from naive spleens were stimulated with plate bound anti-CD3 for 72 hr, in the presence or absence of 50 μg/ml Tc Muc. Proliferation was measured 72 h after stimulation by [3H]thymidine incorporation. *Differences between Tc Muc versus anti-Thy1.1 treatment are significant (P<0.0001).* The inhibition of proliferation by Tc Muc was not observed when control mucin derived from bovine submaxillary glands was used (50 μg/ml). Results are the means ± SD of triplicate cultures of three different experiments. (TIF)
Technology) for 60 min, and the reaction was developed with SuperSignal West Pico chemiluminescence reagents (Pierce). (TH)
