The temperature (T) and frequency (ω) dependent conductivity of weakly disordered Luttinger liquids is calculated in a systematic way both by perturbation theory and from a finite temperature renormalization group (RG) treatment to leading order in the disorder strength. Whereas perturbation theory results in ω/T scaling of the conductivity such scaling is violated in the RG treatment.

We also determine the non-linear field dependence of the conductivity, whose power law scaling is different from that of temperature and frequency dependence.

Interacting one-dimensional electron systems display a large variety of unusual and interesting phenomena, since not only interactions but also external potentials (periodic or random) and thermal fluctuations have pronounced effects on the behavior of these systems.1 2 The hallmark of interaction effects in 1d systems is the power law single particle density of states observable in the backscattering from a single impurity in a Luttinger liquid (LL).3 While the LL spectral function has been observed experimentally,4 the rich behavior of collective scattering by random impurities has eluded experimental observation so far.

In this letter, we focus on the effect of many weak (Gaussian) impurities in a 1d disordered system. For noninteracting electrons, this problem can be solved exactly. Interaction effects are mostly treated perturbatively and described by a dephasing length, which cuts off interference corrections. While this regime of weak interactions has been studied thoroughly,5 6 7, less is known about the opposite regime of strong interactions. For attractive interactions, an unpinning transition as a function of the interaction strength was found.6 7 8. In addition, the power law exponent describing the energy dependence of impurity scattering was predicted to flow as a function of energy.9 Finite temperature effects were partially incorporated by truncating the renormalization group (RG) flow at the de Broglie wave length of plasmon excitations.10 However, for a complete study of the thermal to quantum crossover, quantum and thermal fluctuations have to be considered on an equal footing.11

We calculate the frequency, temperature, and electric field dependence of the conductivity for spinless 1d fermions to leading order in the disorder strength but for arbitrary short range interactions. We go beyond previous approaches1 2 3 4 5 in several respects. From a technical point of view, we i) present a systematic approach to calculate the conductivity from a bosonic self energy in the spirit of5 6, both in perturbation theory and from a finite temperature renormalization group.12 This approach can be generalized to higher orders in the impurity strength to obtain weak localization corrections. We ii) explain that due to a symmetry property of the self energy, an imaginary time RG model has a ballistic density propagator although the retarded density propagator is diffusive. From a physics point of view, we iii) present results for the frequency-temperature crossover including the renormalization of the interaction strength, and show that simple ω/T-scaling is violated in the RG solution. In addition, we iv) calculate the nonlinear field dependence of the conductivity, which is characterized by a novel power law exponent. Our theoretical predictions for weak disorder are in reach of present experimental technology, for instance in carbon nanotubes16 17 18 and polydiacetylen19, where the influence of strong disorder has already been observed. Especially promising experimental systems are bent 2d electron systems in a strong magnetic field20 or quantum Hall line junctions21, in which both interaction and disorder strength can be tuned.

Model.— We consider particles moving in a random potential \( U(x) = \sum_i U_i \delta(x - x_i) \) due to point scatterers with random positions \( x_i \) and density \( n_{\text{imp}} \). The random potential strength \( U_i \) has moments \( \bar{U}_0 = 0 \) and \( \bar{U}_1 = U_{\text{imp}}^2 \delta_{ij} \). Throughout the paper, we use units with \( \hbar = 1 \), \( k_B = 1 \). For noninteracting electrons with Fermi velocity \( v \), one finds a mean free path \( 1/\ell_0 = 2n_{\text{imp}}t_{\text{imp}}^2/v^2 \) by using standard perturbation theory. We will use \( \ell_0 \) as an abbreviation for the disorder strength also in the interacting case. In the replica formalism, a system of spinless interacting 1d electrons is described by the bosonic action

\[
S^{(a)} = \sum_{\alpha,\beta} \int_0^L dx \int_0^{1/T} dt \left\{ \frac{v}{2\pi K} \left[ \left( \partial_x \varphi_\alpha \right)^2 + \frac{1}{v^2} \left( \partial_\tau \varphi_\alpha \right)^2 \right] \delta_{\alpha\beta} + \frac{v^2 A^2}{8\pi^2} \int_0^{1/T} d\tau' \cos \left[ \varphi_\alpha(x, \tau) - \varphi_\beta(x, \tau') \right] \right\}.
\] (1)
Here, \( \Lambda \) denotes the cutoff in momentum space and the interaction strength is parameterized by \( K \), with \( K < 1 \) for repulsive and \( K > 1 \) for attractive interactions. The smooth part of the density is described by \( \frac{1}{2} \partial_x \varphi(x) \),

\[
\text{giving rise to a forward scattering term. Although it}
\]

strongly influences static correlation functions \[15\], it has no effect on dynamic ones and is hence neglected in this analysis. For CDWs, we have \( p = 1 \), and \( p = 2 \) for spinless Luttinger liquids. In the following, we let \( p = 2 \), and the formulae for \( p = 1 \) can be obtained by replacing \( K \rightarrow K/4 \). The optical conductivity can be calculated from the retarded boson Green function as

\[
\sigma(q, \omega) = e^2 K \frac{-i\omega}{q^2 - \frac{\omega}{\omega_c} + \pi^2 K \Sigma^R(q, \omega)}.
\]

The smooth part of the density is described by \( \delta_\alpha,\beta \frac{\Lambda}{2\pi\ell_0} \),

\[
\Sigma^\text{pert}_{\alpha,\beta}(\tau) = -\frac{v^2}{\pi^2 \ell_0} \delta_\alpha,\beta \left[ e^{-2G_0(\tau)} - \delta(\tau) \int_0^{1/T} d\tau' e^{-2G_0(\tau')} \right].
\]

For the bare local bosonic Matsubara Green function we use the expression

\[
G_0(\tau) = K \ln \left( 1 + \frac{\sin(\pi T \tau)}{\pi T / \omega_c} \right)
\]

with \( \omega_c = \Lambda v \). Proper regularization of the Green function is especially important in the RG approach, where the cutoff flows to zero and the Green function needs to be evaluated for energies larger than the cutoff. We calculate the retarded self energy via the analytic continuation \( \Sigma^R(\tau) = -2 \Theta(\tau) \text{Im} \Sigma(\tau \rightarrow i\ell) \) with \( \Theta(\tau) \) denoting the Heavyside step function. After Fourier transforming, one obtains a scaling form of the perturbative self energy

\[
\pi^2 K \Sigma^\text{pert}_{\alpha,\beta}(\omega) = -\delta_\alpha,\beta \frac{\Lambda}{2\pi\ell_0} \left( \frac{\omega}{\omega_c} \right)^{2K-1} F\left( \frac{\omega}{2\pi T} \right),
\]

where the scaling function \( F(x) \) is given by

\[
F(x) = -4x^{1-2K} K^2 \Gamma(-2K) \cdot \frac{\Gamma(1-K-ix)}{\cosh(\pi x) - i\cot(\pi K) \sinh(\pi x) - \Gamma^{-2}(1-K)}.
\]

In the derivation of Eq. [3], \( T/\omega_c \ll 1 \), \( \omega/\omega_c \ll 1 \) was taken and the regularization in Eq. [3] was neglected. The imaginary part of this scaling function is a good approximation for all values of \( K \), its real part only for \( K \ll 0.5 \); however, for \( K \approx 1 \) and larger, the real part of \( \Sigma \) can be neglected compared to the \( \omega^2 \) term in Eq. [3]. Interestingly, the part \( i\cot(\pi K) \sinh(\pi x) \) giving rise to the imaginary part of the self energy vanishes identically for all \( x = in \) with integer \( n \), i.e. it does not appear in the Matsubara self energy. The scaling function has the limiting forms \( \text{Im}[F(x)] \sim i \) for \( x \rightarrow \infty \) and \( \text{Im}[F(x)] \sim ix^{2-2K} \) for \( x \rightarrow 0 \). Thus, interactions renormalize the noninteracting mean free path \( \ell_0 \) with the \( (2-2K) \)-th power of energy. The perturbative expression Eq. [3] is valid for \( \max\left(\frac{\omega_c}{\omega}, \frac{T}{\omega_c}\right) > \frac{1}{\Lambda K} \),

\[
\text{with the renormalized mean free path } \ell = \Lambda^{-1}(\ell_0A/K^2)^{1/(3-2K)}.
\]

Using the asymptotic behavior of \( F(x) \), we find for the real part of the conductivity

\[
\text{Re } \sigma \approx \sigma_0 \begin{cases} \frac{(2\pi T)^{2(1-K)}}{1+(2\pi T)^{2(1-K)}} \frac{\Gamma(1-K)}{\Gamma(2K)} & \frac{\omega}{\omega_c} \ll 1 \\ (\frac{\omega}{\omega_c})^{-2(2-K)} \frac{K}{\Gamma(2K)} & \frac{\omega}{\omega_c} \gg 1 \end{cases}
\]

Here, \( \sigma_0 = e^2 k_0 \ell_0 v \). For \( K \ll 0.5 \), in the regime \( \frac{\omega}{\omega_c} \gg 1 \) a peak at the temperature dependent frequency
FIG. 2: Temperature dependence of the dc conductivity in log-log representation for different values of $K_0$ and $u^0_2 = 10^{-4}$. Lines: Results obtained by truncation of the zero temperature RG equations at the thermal de Broglie wave length (cf. Ref. 3). Symbols: Conductivity calculated from finite temperature RG and the renormalized self energy [14].

For $K = 1$, the Drude conductivity $\sigma = \sigma_0/(1 + \omega^2\nu^2/\ell_0^2)$ is recovered. For $K > 3/2$, perturbation theory is valid for all frequencies, and the conductivity is imaginary with a $1/\omega$ divergence characteristic for a superconductor.

Renormalization.— Since the derivation of the flow equations is well documented in the literature we will here quote only the result [14, 15]. At finite temperature, the flow equations are given by

$$\frac{dK}{dl} = -8u^2KB\left(\frac{K}{2t}\right)\coth\frac{K}{2t}, \quad (8a)$$

$$\frac{du^2}{dl} = \left[3 - 2K\coth\frac{K}{2t}\right]u^2, \quad (8b)$$

$$B(K, y) = \int_0^y \frac{\tau^2 d\tau}{\left[1 + \left(\frac{2\pi \sin \frac{\pi \tau}{2y}}{2y}\right)^2\right]^K} \frac{\cosh(y - \tau)}{\cosh y}. \quad (8c)$$

Here, the dimensionless temperature $t$ obeys the flow equation $\frac{dt}{dl} = t$ with initial value $t_0 \equiv t(l = 0) = TK/\omega_c$, and the dimensionless disorder strength $u^2$ has the initial value $u^0_2 = \frac{1}{v_0\lambda K^2}$. Calculating the self energy by integrating over a momentum shell $\Lambda \exp(-\delta l) < |k| < \Lambda$, we obtain

$$\delta\Sigma_{\alpha\beta}(\tau) = 2K\frac{\cosh[\omega_c(\tau - \frac{1}{T})]}{\sinh(\frac{\omega_c}{2})} \delta l \Sigma^{\text{pert}}_{\alpha\beta}(\tau) \quad (9)$$

for $0 < \tau < 1/T$. Due to the symmetry property $\delta\Sigma_{\alpha\beta}(\tau) = \delta\Sigma_{\alpha\beta}(1/T - \tau)$ in this interval, the low frequency expansion of the Fourier transform $\delta\Sigma_{\alpha\beta}(\omega_n)$ starts with a term $O(\omega_n^2)$, which renormalizes the corresponding term in the action and gives rise to the flow of $K$ in the RG. The analytical continuation $i\omega_n \rightarrow \omega + i\eta$ would not give rise to a diffusive term in the boson propagator. Instead, one has to perform the analytic continuation in the time domain. Although the diffusive part of $\Sigma^R$ does not feed back in the RG, it determines the conductivity in an essential way. The incremental change of the retarded self energy is

$$\delta\Sigma^R(\omega, T, l) = \frac{\Lambda^3v^2u^2e^{-3i\delta l}}{\pi K \sinh(v/2T)} \int_0^\infty dt \frac{e^{\delta i l} - 1}{\left[1 + \left(\frac{\sinh^{\pi T}(\pi T l)}{\pi T / T \sinh^\pi T}\right)^2\right]^K} \text{Im} \left\{ \frac{\exp\left(2K}{i} \arctan\left[\frac{\sinh(\pi T_0)}{\pi T / v\Lambda}\right]\right)}{\cosh\left(-\frac{\nu\Lambda}{2T} + i\nu\Lambda\right)} \right\}. \quad (10)$$

The variables $K, v = K/(\pi\kappa)$ and $\Lambda$ are functions of the RG scale $l$ as determined from the flow equations Eqs. [14]. Note that there is no renormalization of $\kappa$. The retarded self energy to be used in the conductivity Eq. [2] is obtained by integrating over the flow parameter $l$ from zero to infinity. The frequency-temperature crossover of self energy and conductivity is displayed in Fig. 1. One clearly sees that the power law exponent of the frequency dependence changes with energy. Besides the scale dependence of exponents, the conductivity is characterized by the limiting form described in Eq. [14] and the following discussion. The temperature depen-
dence of the dc conductivity is compared to the approximate result \[ ω/T \] in Fig. 2. We observe qualitative agreement between the two approaches. Due to the flow of the Luttinger parameter \( K \), \( ω/T \)-scaling of the self energy is violated (see Fig. 5).

\[
\frac{1}{\ell(E, T)} = -\pi K \text{Im} \left[ \frac{\Sigma(e_0 E\ell(E, T), T)}{e_0 E\ell(E, T)} \right].
\]

Using the perturbative expression Eq. (11), this condition simplifies to \( \ell(E, T) = \left( \frac{e_0 E\ell(E)}{Kω_0} \right)^{2-K} \) for temperatures \( T \ll e_0 E\ell(E) \), and one obtains for the nonlinear dc conductivity

\[
\sigma_{\text{per}}(E) \approx \sigma_0 \left( \frac{e_0 E\ell_0}{Kω_0} \right)^{2-K}.
\]

This zero temperature approximation is valid only for \( K > \frac{1}{2} \), as for lower values of \( K \) a physical solution to Eq. (11) can be found only at finite temperature. In Fig. 3, \( \sigma_{\text{nl}}(E, T) \) as calculated from the perturbative self energy Eq. (11) is shown.

\[
\sigma_{\text{nl}}(E, T) = \sigma_{\text{per}}(E) \left[ 1 + \kappa E^{\nu} \right].
\]

Conclusions.— We have discussed frequency, temperature, and field dependence of charge transport in a disordered LL in a bosonized theory. The conductivity is obtained from the boson self energy, which is integrated from the flow equations of a finite temperature RG. In contrast to single impurity physics in a LL, the power law exponent describing impurity scattering is scale dependent in the disordered case. The mean free path in nonlinear dc transport is selfconsistently calculated by replacing the photon energy in the ac self energy by the average electron energy acquired between scattering events.
