Abstract: The flowers of Narcissus poeticus are used for the isolation of valuable fragrance substances. So far, as the majority of these substances consist of volatile and sensitive to heat compounds, there is a need of developing effective methods for their recovery. In this study, freeze-dried N. poeticus inflorescences were extracted with pure supercritical CO₂ (SFE-CO₂) and its mixture with 5% co-solvent ethanol (EtOH) at 40 °C. Extract yields varied from 1.63% (12 MPa) to 3.12% (48 MPa, 5% EtOH). In total, 116 volatile compounds were identified by GC-TOF/MS in the extracts, which were divided into 20 different groups. Benzy1 benzoate (9.44–10.22%), benzy1 linoleate (1.72–2.17%) and benzy1 alcohol (0.18–1.00%) were the major volatiles among aromatic compounds. The amount of the recovered benzy1 benzoate in N. poeticus SFE-CO₂ extracts varied from 58.98 ± 2.61 (24 MPa) to 91.52 ± 1.36 (48 MPa) mg/kg plant dry weight (pdw). α-Terpineol dominated among oxygenated monoterpenes (1.08–3.42%); its yield was from 9.25 ± 0.63 (12 MPa) to 29.88 ± 1.25 (48 MPa/EtOH) mg/kg pdw. Limonene was the major monoterpane hydrocarbon; (3E)-hexenol and heneicosanol dominated among alcohols and phenols; dihydroactinidiolide and 4,8,12,16-tetramethyl heptadecan-4-olide were the most abundant lactones; heptanal, nonanal, (2E,4E)-decadienal and octadecanal were the most abundant aldehydes. The most important prenol lipids were triterpenoid squalene, from 0.86 ± 0.10 (24 MPa) to 7.73 ± 0.18 (48 MPa/EtOH) mg/kg pdw and D-α-tocopherol, from 1.20 ± 0.04 (12 MPa) to 15.39 ± 0.31 (48 MPa/EtOH) mg/kg pdw. Aliphatic hydrocarbons (waxes) constituted the main part (41.47 to 54.93%) in the extracts; while in case of a 5% EtOH the percentage of alkanes was the lowest. The fraction of waxes may be removed for the separation of higher value fragrance materials. In general, the results obtained are promising for a wider application of SFE-CO₂ for the recovery of fragrance substances from N. poeticus flowers.

Keywords: Narcissus poeticus; SFE-CO₂ extraction; volatile composition; aroma compounds

1. Introduction

Aromatic herbs and flowers are an important source of natural ingredients for the development of flavours and fragrances. Narcissus is a genus of perennial spring flowering plants of the Monocotyledon family Amaryllidaceae. Carl Linnaeus originally defined six species of Narcissus in 1753, while N. poeticus was the first one described in his book Species Plantarum [1]. Nowadays the genus is generally considered to consist of about 12 sections with approximately 80 species. Poetic, commonly also called daffodil (N. poeticus), supposed (N. pseudonarcissus), tripod (N. triandrus), and bouquet (N. tazetta) narcissus are the most widely grown species, while cyclamen (N. cyclamineus), chaste (N. papyraceus), and fragrant (Narcissus × odorus) are less popular. Three species, namely white (N. poeticus), bouquet (N. tazetta) and yellow/supposed (N. pseudonarcissus) are most popular in Lithuania as ornamental plants in flower gardens, which also grow in old parks and meadows. N. poeticus is a wild, bulbous herbaceous plant, growing up to 20–40 cm height. The leaves are radical, green, narrow and long; it blooms in late spring (April–May) with an extremely fragrant white flower per stem [2]. N. poeticus is thought to originate from the...
Middle East or Eastern Mediterranean; now it is spread all over Europe, particularly France, Spain, southern Italy and north-western Greece [3]. It is also naturalized in New Zealand, British Columbia, Canada, United States, North Africa, and Asia.

The plants of the Amaryllidaceae family have also been used as herbal remedies since ancient times. The *Narcissus* genus is a rich source of potentially valuable pharmaceuticals, such as alkaloids galanthamine, lycorine, isoquinolines narciclasine, pancreatistatin, (E)-dihydrornarciclasine, and their corresponding 7-deoxyanalogues, narciclasine, norlycoramine; some of them might be promising in the treatment of Alzheimer’s and oncological diseases [4–8]. Health beneficial chlorogenic (755.93 ± 4.06 µg/g), p-coumaric, ferulic acids and flavonoids (hyperoside, isoquercitrin, quercitrin) were reported in *N. poeticus* ethanolic extract from Romania [9].

Essential oils and extracts used in the perfumery industry are mostly produced from *N. jonquilla*, *N. poeticus*, *N. tazetta* and some other species. *N. poeticus* flowers as exceptionally fragrant material are cultivated in the Netherlands and southern France mainly for distilling essential oil (EO). Groom [10] described the aroma of the narcissus oil as resembling the combination of jasmine and hyacinth; therefore, its floral concrete or absolute has been used as a principal ingredient in ~11% of modern quality perfumes, including such famous names as “Fatale” or “Samsara”. The absolute of narcissus flowers has been widely used not only in popular classical perfumes in combination with rose, jasmine, violet and etc., but also in sophisticated modern perfumes, especially for strong pungent, green, woody and deep floral scent, which blends well with many other floral absolutes, such as ylang-ylang, jasmine, neroli, mimosa, clove bud carnation and others [2,11].

Industrially the absolutes are produced by extraction with organic solvent (hexane or other), its evaporation (causing some loss of volatile compounds), and removal of waxes. The distillation of fresh daffodil flowers recovers pure fraction of volatiles (essential oil), which are free of larger molecular weight waxes. However, the yields of EO are very low; for example, only 0.05% [12], while there is a risk of thermal degradation of some volatile compounds [11]. Nowadays green technologies for the isolation of valuable substances from plant materials are highly preferable in terms of safety and environmental protection; thus, instead of traditional distillation and/or solid-liquid extraction methods, the supercritical fluid extraction with carbon dioxide (SFE-CO$_2$) was applied in our study for the recovery of lipophilic fraction containing fragrant volatile constituents. SFE-CO$_2$ has been widely used for the recovery of EO together with other lipophilic constituents [13]. SFE-CO$_2$ possesses many advantages (nontoxic, non-flammable, inexpensive, extraction at low temperatures avoids thermal degradation of the compounds and yields high purity extracts) and therefore can be successfully explored in pharmaceutical, cosmetics, food and other industries for recovery of valuable lipophilic constituents. On the other hand, the disadvantage of SFE-CO$_2$ in the isolation of EO is that the extract also contains non-volatile lipophilic constituents.

More than 430 volatile compounds have been reported in *Narcissus* spp. [12,14–19]. For instance, 103 and 66 compounds were identified in *N. trevithian* and *N. geranium* oil, respectively, while only 20 of them were common for both species [17]. In the plants from Greece (E)-ocimene (61.12%) was dominant for *N. tazetta* and benzyl acetate (19.36%) for *N. serotinus* among 19 identified in the EOs constituents [12]. The main volatiles of *N. tazetta* absolute from Italy were γ-terpinene (27.21%), methyl cinnamate (15.84%), benzyl acetate (9.58%), benzyl alcohol (4.79%) and benzyl benzoate (4.00%) [18]. Eleven compounds were identified in the headspace of narcissus flowers; benzyl acetate (44.0%), 3,4- and 3,5-dimethoxy toluene (10.0 and 25.0%), and indole (5.0%) were major in the living flowers, whereas the percentages of the same compounds in the picked flowers were 30–43%, 18–39.5% and 0.3–1.0% [15]. (E)-β-Ocimene was found in high percentages in six species of *Narcissus* grown in Spain [19]. The main constituents of the Chinese narcissus flowers were (E)-β-ocimene (62.73–66.06%), benzyl acetate (11.65–25.02%), (Z)-β-ocimene, 1,8-cineole, and linalool [20].
Volatile compounds of *N. poeticus* have also been studied [2,11,21,22]. Ehret et al. [22] identified 80 new minor volatile components in *N. poeticus* absolute from France “Massif central”, α-terpineol (23.7%), methyl (E)-isoeugenol (20.0%), and benzyl benzoate (19.4%) being the major ones; more than 20 of them were considered as responsible for the complex floral notes reminiscent of “rose”, “jasmine”, “violet”, “tuberose” and “orange flower”. Cinnamyl alcohol (29.91 µg/g), methyl isoeugenol (28.07 µg/g), isoeugenol (23.12 µg/g), methyl eugenol (20.72 µg/g), and α-terpineol (20.31 µg/g) were the main components in hexane extract of fresh *N. poeticus* flowers of Rocca di Mezzo [11], whereas cinnamyl alcohol (30.2 µg/g), benzyl benzoate (28.5 µg/g), isoeugenol methyl ether (28.1 µg/g), (Z)-ocimene (25.2 µg/g), isoeugenol (22.9 µg/g) were quantitatively major in the plants from Sirente-Velino (Abruzzo region, Italy) [2]. To the best of our knowledge, only one article is available on SFE-CO$_2$ of *N. poeticus* [11]; however, this study applied comparatively low pressure of the fluid CO$_2$ (12 MPa). So far, as the solubility of many compounds increases with increasing solvent density, which depends on its pressure, in our study we applied CO$_2$ pressure up to 48 MPa. It is important to mention that some of these volatiles are stated as more or less allergenic compounds, for example, cinnamyl alcohol, isoeugenol and cinnamyl aldehyde, and their use must follow legislation. It was suggested that in the preparation of safer perfumes absolute can be obtained from the corona only instead of tepals plus corona [2].

Considering previously reported data, our study aimed at evaluating the effects of pressure and addition of co-solvent in SFE-CO$_2$ of freeze-dried *N. poeticus* flowers. Extract yields and comprehensive analysis of the recovered volatiles compounds were performed for this purpose. It is expected that the data obtained will expand our knowledge on the composition of *N. poeticus* fragrant constituents and the possibilities of their recovery by using green extraction techniques.

### 2. Results and Discussion

#### 2.1. Extract Yields

The yields of the SFE-CO$_2$ extracts of *N. poeticus* freeze-dried flowers varied from 1.63 ± 0.29 to 3.12 ± 0.12% (Table 1). The temperature of 40 °C, static extraction time 10 min and dynamic extraction time of 120 min were kept constant in all experiments. According to the literature reports, the yields of the concrete (absolute + waxes) obtained with hexane extraction were 0.2–0.3% [22], 0.41–0.45% [2,11] of fresh flowers and with petroleum ether –0.2% of fresh flowers [23]. The percentages of absolute in the concretes varied from 27 to 37% [11,23].

| SFE-CO$_2$ Extraction Conditions | Extract Yield, % |
|----------------------------------|-----------------|
| 12 MPa                           | 1.63 ± 0.29     |
| 24 MPa                           | 1.75 ± 0.10     |
| 36 MPa                           | 1.82 ± 0.09     |
| 48 MPa                           | 2.36 ± 0.09     |
| 48 MPa + 5% EtOH                 | 3.12 ± 0.12     |

Results are expressed as a mean ± standard deviation (n = 3); Values within columns followed by the same letter (a–c) do not differ statistically at $p < 0.05$ (Duncan test).

There were no statistical differences in the extract yields at 12–36 MPa, while at 48 MPa the yield of the recovered fraction was significantly higher ($p < 0.05$). Additionally, 5% ethanol applied as a co-solvent increased extract yield by ~32% (from 2.36 to 3.12%) compared with pure SFE-CO$_2$ at 48 MPa. Ferri et al. [11] compared conventional hexane extraction with SFE-CO$_2$ of *N. poeticus*; however, the absolute yields of SFE-CO$_2$ extracts are not available in their article. Nevertheless, it is evident that SFE-CO$_2$ extracts contained all the main constituents, which were identified in hexane extracts, while their yields in
2.2. Composition of *N. poeticus* SFE-CO$_2$ Extracts

The detailed list of extracted by SFE-CO$_2$ volatile compounds, their percentage composition and odour descriptions are presented in Table 2. In total, 116 compounds were identified in the SFE-CO$_2$ extracts of *N. poeticus* flowers obtained under different extraction conditions. The sums (in %) and the numbers of the identified compounds in SFE-CO$_2$ extracts at 12 MPa, 24 MPa, 36 MPa, 48 MPa and 48 MPa/EtOH were 77.47/105, 74.12/100, 76.07/104, 74.10/93, and 76.69/92, respectively.

It is evident that the composition of *N. poeticus* SFE-CO$_2$ extracts is very complex, therefore for further discussion all the identified compounds were divided into 20 different classes, namely aromatics, aliphatic hydrocarbons, aromatic hydrocarbons, monoterpene hydrocarbons, oxygenated monoterpenes, oxygenated sesquiterpenes, esters, alcohols, aldehydes, ketones, lactones, acids, amides, diterpenoids, triterpenoids, tocopherols, phenylpropanoids, phenols and others (including oxanes, heteroaromatics, etc) (Table 2).

2.2.1. Aromatics

Aromatic compounds is the most important group of volatiles in *N. poeticus* SFE-CO$_2$ extracts; their percentage content varied from 12.55% (24 MPa) to 14.32% (48 MPa/EtOH). The major compounds were benzyl benzoate (65, 9.44–10.22%), benzyl linoleate (107, 1.72–2.17%), benzyl alcohol (12, 0.18–1.00%) and benzyl linolenate (108, 0.26–0.53%). Other aromatic compounds include hydrocinnamyl alcohol (30), 2-phenylethyl benzoate (70), benzyl 4-methoxybenzoate (75), benzoic acid hexadecyl ester (104), benzoic acid (21), benzyl oleate (106) (<0.1–0.2%), while hexyl benzoate (60) and (3Z)-hexenyl benzoate (58) were detected in trace amounts (Table 2).

Benzyl benzoate, benzyl alcohol and benzoic acid are used in a wide variety of cosmetics formulations as fragrance ingredients and preservatives. The group of benzyl derivatives was reaffirmed as generally recognized as safe (GRAS) by the Expert Panel of the Flavour and Extract Manufacturers (FEMA), and the evidence of safety is supported by the fact that the intake of benzyl derivatives as natural components of traditional foods is larger than their intake in the case of intentional adding as flavouring substances [24]. Benzyl alcohol is an aromatic alcohol, which has been characterised as possessing “sweet, flower” [25] and “berry, cherry, grapefruit, citrus, and walnut” [26] odour notes. The absolute amounts of main volatile compounds in mg/kg pdw are summarised in Figures 1 and 2. The highest recoveries of benzyl alcohol (12, 8.79 ± 0.59 mg/kg pdw), as well as benzyl linoleate (107, 18.96 ± 0.42 mg kg pdw) were obtained at 48 MPa/EtOH; however this value was not significantly different to the one obtained at 48 MPa (Figure 1A). Benzyl benzoate and benzyl alcohol were previously reported in high amounts in the absolutes of hexane extracts of *N. poeticus* from Italy [2,11].

Values within rows followed by the same superscript letter (a–e) do not differ statistically at p < 0.05 (Duncan test).
Figure 1. The absolute amounts of the main volatile compounds of major classes ((A)—Aromatics, (B)—Oxygenated monoterpenes and sesquiterpenes, (C)—Alcohols and phenols, (D)—Esters) of *Narcissus poeticus* SFE-CO₂ extracts, in mg/kg pdw. Constituents are numbered by the same order as provided in Table 2. Values within columns followed by the same letter (a–e) do not differ statistically at $p < 0.05$ (Duncan test).
Figure 2. The absolute amounts of main volatile compounds of major classes ((A)—Acids, (B)—Lactones, (C)—Aldehydes, (D)—Amides and prenol lipids) of *Narcissus poeticus* SFE-CO$_2$ extracts, in mg/kg pdw. Constituents are numbered by the same order as provided in Table 2. Values within columns followed by the same letter (a–e) do not differ statistically at $p < 0.05$ (Duncan test).
It was reported that narcissus absolute has “a very strong, green, earthy and woody” odour, and that in appropriate dilution, releases a characteristic blend of floral and balsamic notes: light floral notes (rose or jasmine), deep floral notes (ylang-ylang, tuberose, orris and violet), notes of the balsamic type (styrax) and woody, earthy scents (oakmoss or patchouli) [22]. The balsamic type (styrax) flavour notes can be associated with the presence of benzoates and cinnamates in the N. poeticus SFE-CO$_2$ products composition. Benzyl benzoate also possesses “balsamic, oil, herb” [25] and “almond, cheese, cherry, floral, pineapple, strawberry, sweet” [26] aroma notes. The absolute amount of the recovered benzyl benzoate from N. poeticus by SFE-CO$_2$ varied from 58.98 ± 2.61 mg/kg pdw (24 MPa) to 91.52 ± 1.36 mg/kg pdw (48 MPa) (Figure 1A).

It was also reported that benzyl benzoate, its derivatives and benzyl cinnamate may be promising compounds in reducing hypertension [28]. It may be concluded that N. poeticus SFE-CO$_2$ extracts after the separation of waxes might be a potential natural source of benzyl benzoate and benzyl alcohol.

2.2.2. Monoterpane Hydrocarbons, Oxygenated Monoterpenes and Sesquiterpenes

α-Terpineol (25), which possess “oil, anise, mint” [25] and “lilac” [26] aroma notes, was major constituent among oxygenated monoterpenes (1.08–3.42%); it was also reported previously in N. poeticus absolute in comparatively high percentages [2,11,22]. The absolute amount of the recovered α-terpineol in N. poeticus SFE-CO$_2$ extracts increased by increasing pressure and varied from 9.25 ± 0.63 mg/kg pdw (12 MPa) to 29.88 ± 1.25 mg/kg pdw (48 MPa/EtOH) (Figure 1B). It is well known that the quantitatively minor and even trace components can be important on the overall odour quality of flavours and fragrances. Consequently, the presence of ketones β-ionone epoxyde (0.28–0.42%) and trace component β-ionone may be important even at low concentrations (≤0.04%) by providing “violet flower aroma notes” of narcissus.

Limonene was the major monoterpane hydrocarbon; however, its percentage was low (0.08–0.17%). It is interesting that (E)−β-ocimene was not found in SFE-CO$_2$ extracts of N. poeticus from Lithuania, while this compound was reported to be present in six species of Narcissus from Spain [19], N. tazetta EOs from Greece and N. poeticus absolute from Italy [2].

2.2.3. Alcohols, Phenols, Lactones, Aldehydes and Other Volatiles

Among alcohols and phenols (3E)-hexenol (1) and heneicosanol (101) were recovered at the highest amounts (Figure 1C). (3E)-Hexenol is very abundant in various aromatic and spicy plants and possesses “moss” and “fresh” aroma notes. Therefore it may provide “green, woody” scents for narcissus even at low percentage concentrations, which varied from 0.10 ± 0.02% (36 MPa) to 0.89 ± 0.06% (48 MPa) (Table 2). The recovery of long-chain alcohol heneicosanol from N. poeticus by SFE-CO$_2$ varied from 6.07 ± 0.30 mg/kg pdw (24 MPa) to 10.47 ± 0.62 mg/kg pdw (12 MPa) (Figure 1C).

The recoveries of esters (Figure 1D) and acids (Figure 2A) were quite low; however, it is interesting to mention that the amounts extracted from N. poeticus ethyl hexadecanoate (78), ethyl linolenate (90) and linoleic acid (86) significantly increased at 48 MPa and adding 5% of EtOH. It is believed that high amount of alcohols and long-chain acids in narcissus has more effect on the longer lasting trait of its odour, rather than on the odour quality [17].

Dihydroactinidiolide (57, 0.42–0.64%) and 4,8,12,16-tetramethyl heptadecan-4-olide (98, 0.27–0.50%) were the most abundant lactones in the SFE-CO$_2$ extracts of N. poeticus (Figure 2B). The absolute content of dihydroactinidiolide was from 3.57 ± 0.23 mg/kg pdw (12 MPa) a to 5.70 ± 0.10 mg/kg pdw (48 MPa). Dihydroactinidiolide is a lactone (cyclic ester) resulting from the secondary oxidation of β-ionone through the intermediate 5,6-epoxy-β-ionone [29]. It possesses a “sweet, tea-like” odour and is used as a fragrance. Dihydroactinidiolide occurs naturally in plant leaves, black tea, fenugreek, fire ants, fruits, tobacco and it is a pheromone for a variety of insects [30]. Dihydroactinidiolide was reported to accumulate in Arabidopsis leaves under high light stress [31] and to exhibit cytotoxic effects against cancer cell lines [32].
Heptanal (2), nonanal (19), (2E,4E)-decadienal (37) and octadecanal (80) were the most abundant aldehydes (Figure 2C). Nonanal possesses very complex odour (Table 2) including “green” and “rose” scents. Its content in the extracts was 0.31–0.48%, while the absolute amounts, which were recovered from the flowers, varied from 2.70 ± 0.06 mg/kg pdw (48 MPa/EtOH) to 3.82 ± 0.16 mg/kg pdw (48 MPa) (Figure 2C). The amount of octadecanal was from 2.58 ± 0.18 mg/kg pdw (24 MPa) to 4.10 ± 0.22 mg/kg pdw (12 MPa). Octadecanal (or stearyl aldehyde) is a long chain fatty aldehyde and was identified as a biologically active pheromone component. Octadecanal is often used as the substrate of choice to test the microsomal enzyme fatty aldehyde dehydrogenase activity in patients suspected of having Sjögren-Larsson syndrome (autosomal recessively inherited neurocutaneous disorder) [33].

2.2.4. Triterpenoids, Tocopherols and Others

Supercritical CO\(_2\) together with volatile compounds also extracts higher molecular weight lipophilic compounds, among them important prenol lipids such as triterpenoid squalene and tocopherols, which are well known antioxidants. Squalene is a long chain triterpene hydrocarbon, which is a precursor in the synthesis of sterols. The amount of squalene varied from 0.86 ± 0.10 mg/kg pdw (24 MPa) to 7.73 ± 0.18 mg/kg pdw (48 MPa/EtOH). It is worth noting that the use of a co-solvent ethanol increased the amount of extracted squalene ~2.5 times (Figure 2D). The antioxidant and oxygen carrying properties of squalene predicts its potential use in preventing cardiovascular diseases and cancer [34].

The amount of the recovered vitamin E (D-\(\alpha\)-tocopherol) was from 1.20 ± 0.04 mg/kg pdw (12 MPa) to 15.39 ± 0.31 mg/kg pdw (48 MPa/EtOH). In nature, there are four main structures of tocopherols, namely \(\alpha\)-, \(\beta\)-, \(\gamma\)-, and \(\delta\)-tocopherol. Tocopherols are lipophilic molecules which are synthesized by plant cells and stored in leaves and seeds, and are endowed with antioxidant functions. They possess multiple beneficial healthy effects, such as the prevention of cardiovascular diseases and cancer [35].

The amide of oleic acid (Z)-9-Octadecenamide (99) and amide of palmitic acid–hexadecanamide (91), which are fatty acid derivatives, were determined in the lipophilic fraction. The percentage of (Z)-9-octadecenamide (99) was from 0.44 to 1.00% (Table 2) and the absolute amount (Z)-9-octadecenamide varied from 3.25 ± 0.13 mg/kg pdw (24 MPa) to 8.76 ± 0.96 mg/kg pdw (48 MPa/EtOH) (Figure 2D). Oleamide was reported in various natural plant materials such as Nigella sativa [36], mountain celery seeds [37] and other plants [38], however it should be noted that it may be an artefact, which is transferred into the extracts from the labware [39]. The health-promoting properties of (Z)-9-octadecenamide have been reported for this oleamide, such as anti-inflammatory and antibacterial activities [36], hypolipidemic activity [37], against Alzheimer disease [38], and etc.

Some of the components depending on different classes were identified in narcissus extract when the highest pressure and addition of 5% ethanol as co-solvent were applied, e.g., pantolactone (13), ethyl heptanoate (17), benzoic acid (21), (E)-8-hydroxylinalool (40), 3-hydroxydecanoic acid (56), ethyl tetradecanoate (66), ethyl 9-octadecenoate (88).

2.2.5. Aliphatic Hydrocarbons (Waxes)

It was observed that the saturated hydrocarbons (n-alkanes) constitute a very large fraction in the total amount (from 41.47 to 54.93%) of GC-detectable volatiles of the narcissus lipophilic fraction (SFE-CO\(_2\) extracts). The percentage of n-alkanes slightly decreased by increasing pressure; it was expected additionally that by applying 5% ethanol as a co-solvent the percentage amount of alkanes was the lowest (41.47%). Higher n-alkanes, such as heptacosane (105, 11.21–15.40%), tricosane (96, 7.57–11.36%), nonacosane (111, 5.64–7.27%), untriacontane (115, 4.41–6.73%), pentacosane (102, 4.18–6.13%) and heneicosane (81, 3.71–5.50%) were the major qualitative compounds in this fraction (Table 2).
The highest absolute amounts of aliphatic hydrocarbons were extracted at 12 MPa, while the lowest at 24 MPa. Further increase in pressure from 24 to 48 MPa resulted in the increase in the recovered amounts of n-alkanes, while in the case of using ethanol it was reduced again. For example, the highest amount of the recovered n-heptacosane (105) was 131.49 ± 7.00 mg/kg pdw at 12 MPa and the lowest 84.07 ± 1.37 mg/kg pdw at 24 MPa (Figure 3). At further increase in pressure its amount increased to 121.88 ± 5.30 mg/kg pdw (48 MPa), while 5% ethanol reduced the value to 98.08 ± 5.30 mg/kg pdw, which was significantly lower to that extracted at 12 MPa. The amount of these saturated acyclic alkanes could be reduced by using conventional dewaxing procedures.

**Figure 3.** The absolute amounts of aliphatic hydrocarbons in *Narcissus poeticus* SFE-CO\(_2\) extracts, in mg/kg pdw. Constituents are numbered by the same order as provided in Table 2. Values within columns followed by the same letter (a–e) do not differ statistically at \(p < 0.05\) (Duncan test).

**3. Materials and Methods**

**3.1. Plant Material and Chemicals**

*Narcissus poeticus* L. plants were grown in a farmstead near the city of Klaipeda (Lithuania, coordinates: 55°45’ N 21°10’ E) and the flowers were collected at a full flowering stage. The flowers were picked in the morning manually, separated from the stems by scissors. Fresh flowers were frozen to \(-40^\circ\text{C}\) and freeze-dried in a Sublimator 40 at 0.05 mbar pressure (Zirbus Technology, Bad Grund, Germany). The dried flowers were ground in an ultra-centrifugal mill ZM 200 (Retsch, Haan, Germany) using 0.5 mm hole size sieve.

Pentane (for residue analysis, \(\geq 99.0\%\)) was from Sigma-Aldrich (Steinheim, Germany), Ethanol (\(\geq 96\%\)) obtained from Joint Stock Company Stumbras, Lithuania. \(C_7\text{–}C_{30}\) saturated n-alkanes standard and internal standard (decane) were from Supelco Analytical (Bellefonte, PA, USA). The following reference compounds (95–99% purity) for the identification of narcissus volatiles were purchased from Fluka, Sigma-Aldrich or Supelco: limonene, \(p\)-cymene, \(\alpha\)-terpineol, vanillin, benzyl alcohol, nonanal, \(\beta\)-ionone, caryophyllene oxide, squalene.

**3.2. Supercritical Carbon Dioxide Extraction (SFE-CO\(_2\))**

SFE-CO\(_2\) was carried out in a supercritical fluid extractor Helix (Applied Separation, Allentown, PA, USA). Each extraction was performed from 10 g of ground *N. poeticus* flowers placed in a 50 mL cylindrical extractor vessel (14 mm \(\times\) 320 mm; \(h/d = 22.86\)), between two layers of defatted cotton wool in both ends, to avoid particles clogging the system. The temperature of the extraction vessel was controlled by a surrounding heating jacket. The flow rate of CO\(_2\) in the system (\(v\)) was controlled manually by the micrometering valve (back-pressure regulator). The volume of CO\(_2\) consumed was measured
by a ball float rotameter and a digital mass flow meter in liters per min (SL/min) at
standard state: pressure P = 100 kPa, temperature T = 20 °C, density ρ = 0.0018 g/mL.
The conditions for extraction were set as follows (see in Table 1): extraction time 120 min,
pressure 12–48 MPa, extraction temperature 40 °C, flow rate of CO₂ 2 L/min. A static time
of 10 min was included in to the total extraction time and was constant. The extraction at
48 Mpa was also performed using 5% (v/v) ethanol as a co-solvent in order to enhance the
polarity of the solvent mixture. The extracts were collected in brown glass bottles at room
temperature and atmospheric pressure and stored at −20 °C until further analysis.

3.3. Gas Chromatography–Time-of-Flight Mass Spectrometry (GC-TOF/MS)

For qualitative and quantitative composition of SFE-CO₂ extracts of N. poeticus flow-
ers, they diluted in pentane (10 mg/mL) containing 0.2% internal standard and analysed
on a GC × GC-TOFMS LECO Pegasus 4D system, consisting of an Agilent 7890A GC, a
GERSTEL Multipurpose Sampler MPS (Gerstel GmbH, Mulheim an der Ruhr, Germany),
a high-speed TOF/MS detector (LECO, St. Joseph, MI, USA) and a four jet cryogenic
modulator (Zoex, Houston, TX, USA) by comparing the 1D first dimension linear temper-
ature programmed Kováts retention index with the peak identities provided by a mass
spectral similarity search. The column set consisted of a primary column BPX-5 (30 m,
0.25 mm i.d., 0.25 µm film thickness) (SGE Analytical Science, Australia) connected to a
secondary column, BPX-50 (1.8 m, 0.10 mm i.d., 0.1 µm film thickness). The primary oven
was programmed as follows: 50 °C ramped to 100 °C at 10 °C/min (0 min) further ramped
to 300 °C at 5 °C/min (hold 5 min); the secondary oven programming was from 65 °C
ramped to 115 °C at 10 °C/min (0 min) then ramped to 315 °C at 5 °C/min (hold 5 min).
The transfer line temperature was 250 °C, the GC injector port was kept at 280 °C with
desorption time of 5 min.

The TOF/MS acquisition rate was 10 spectra/s, the mass range used for identification
was from 35–550 m/z units. Detector’s voltage was set at 1550 V and ion source temperature
of 250 °C. Data from the GC × GC-TOF/MS system were collected by ChromaTOF software
v.4.22 (LECO) after a solvent peak delay of 420 s in a splitless mode for 30 s, a further valve
was opened and purge flow was 20 mL/min; mass spectrum assignment was based on
matching against Adams, NIST, MainLib, RepLib mass spectra libraries; signal-to-noise
threshold was set as 50 with the minimum similarity accepted was 700. The mean values
were calculated from triplicate injections.

Quantitative data were obtained by peak area normalization without using correction
factors as the means of triplicate GC-TOF/MS runs and expressed as peak area percentage
and recalculated in mg/kg per plant dry weight (mg/kg pdw). Quantitative data were
were calculated using the formula: \[ m_i = \left( \frac{m_D \times A_i}{A_D \times RF_i} \right) \times \left( \frac{Y_e \times 1000/100}{m_e} \right), \]
where \( m_i \) is the mass of the individual compound \( i \) to be quantified, expressed in mg/kg
per plant dry weight (mg/kg pdw); \( m_D \) mass of decane (internal standard, IS), \( A_i \) and \( A_D \)—are
the peak area of the analyte \( i \) and the IS, respectively, \( RF_i \)—response factor of individual
compound; \( Y_e \)—the yield of the extract (%), \( m_e \)—the mass of the extract (g).

The identification of volatile components was assigned by comparing their Kováts
Retention Indices (KI) relative to C_7–C_30 n-alkanes, obtained on nonpolar BPX-5 column
with those provided in literature [27] and by comparing their mass spectra with the data
provided by the NIST, MainLib, RepLib and Adams mass spectral libraries. The identity
of some constituents was confirmed by co-injection of reference compounds. Positive
identification was assumed when good match of mass spectrum and KI was achieved.

3.4. Statistical Analysis

All analyses were replicated at least three times and all data are reported as mean
values ± standard deviations (SD) using MS Excel 2010 software. Data were statistically
handled by one-way analysis of variance (ANOVA, vers. 2.2), significant differences among
the samples were evaluated by the Duncan’s multiple-range test at the probability level of
\( p < 0.05 \).
4. Conclusions

*Narcissus poeticus* flowers were extracted with supercritical carbon dioxide at different solvent pressures, from 12 to 48 MPa. The yield of lipophilic fraction significantly increased after raising the pressure from 36 to 48 MPa and by adding 5% of a co-solvent ethanol into the CO₂ flow. Generally, the yields were higher compared with the previously reported data for conventional extraction with organic solvents. In total, 116 volatile compounds were identified by GC-TOF/MS in the extracts. The most important for *N. poeticus* odour constituents benzyl benzoate (9.44–10.22%), benzyl linoleate (1.72–2.17%) and benzyl alcohol (0.18–1.00%) were the major volatiles among aromatic compounds. The extracts contained a large fraction of waxes, which are not desirable in the production of higher quality fragrance ingredients; however, adding a co-solvents ethanol enabled the reduction in the percentage of higher alkanes, while the amount of the recovered benzyl aromatics increased. On the other hand, for practical purposes, SFE-CO₂ at 48 MPa would most likely be preferable because in this case the process becomes less complicated and cheaper; there is no need for a co-solvent pump and removal of it after extraction, which may result in some loss of volatile fragrance constituents. However, adding co-solvent increases the recovery of an important bioactive compound α-tocopherol approx. 2-fold. In general, the results obtained are promising for a wider application of supercritical extraction for the recovery of fragrance substances from *Narcissus poeticus* flowers.
