ON THE MODULI SPACES OF SEMI-STABLE PLANE SHEAVES OF DIMENSION ONE AND MULTIPLICITY FIVE

MARIO MAICAN

Abstract. We find locally free resolutions of length one for all semi-stable sheaves supported on curves of multiplicity five in the complex projective plane. In some cases, we also find geometric descriptions of these sheaves by means of extensions. We give natural stratifications for their moduli spaces and we describe the strata as certain quotients modulo linear algebraic groups. In most cases, we give concrete descriptions of these quotients as fibre bundles.

1. Introduction

Let $M_{\mathbb{P}^2}(r, \chi)$ denote the moduli space of semi-stable sheaves $\mathcal{F}$ on the complex projective plane $\mathbb{P}^2$ with support of dimension 1, multiplicity $r$ and Euler characteristic $\chi$. The Hilbert polynomial of $\mathcal{F}$ is $P_{\mathcal{F}}(t) = rt + \chi$ and the ratio $p(\mathcal{F}) = \chi/r$ is the slope of $\mathcal{F}$. We recall that $\mathcal{F}$ is semi-stable, respectively stable, if $\mathcal{F}$ is pure (meaning that there are no proper subsheaves with support of dimension zero) and any proper subsheaf $\mathcal{F}' \subset \mathcal{F}$ satisfies $p(\mathcal{F}') \leq p(\mathcal{F})$, respectively $p(\mathcal{F}') < p(\mathcal{F})$. The spaces $M_{\mathbb{P}^2}(r, \chi)$ for $r \leq 3$ are completely understood from the work of Le Potier [8], and others. In [4], Drézet and the author studied the spaces $M_{\mathbb{P}^2}(4, \chi)$. This paper is concerned with the geometry of the spaces $M_{\mathbb{P}^2}(5, \chi)$. In view of the obvious isomorphism, $M_{\mathbb{P}^2}(r, \chi) \cong M_{\mathbb{P}^2}(r, \chi + r)$ sending the stable-equivalence class of a sheaf $\mathcal{F}$ to the stable-equivalence class of the twisted sheaf $\mathcal{F} \otimes \mathcal{O}(1)$, it is enough to assume that $0 \leq \chi \leq 4$. According to [8], the spaces $M_{\mathbb{P}^2}(5, \chi)$ are projective, irreducible, locally factorial, of dimension 26 and smooth at all points given by stable sheaves. In particular, $M_{\mathbb{P}^2}(5, \chi)$, $1 \leq \chi \leq 4$, are smooth.

In this paper, we shall carry out the same program as in [4]. We shall decompose each moduli space into locally closed subvarieties, called strata, by
means of cohomological conditions. Given a stratum $X \subset \mathcal{M}_{\mathbb{P}^2}(5,\chi)$, we shall find locally free sheaves $\mathcal{A}$ and $\mathcal{B}$ on $\mathbb{P}^2$ such that each sheaf $\mathcal{F}$ giving a point in $X$ admits a presentation

$$0 \longrightarrow \mathcal{A} \overset{\varphi}{\longrightarrow} \mathcal{B} \longrightarrow \mathcal{F} \longrightarrow 0.$$ 

The linear algebraic group $G = (\text{Aut}(\mathcal{A}) \times \text{Aut}(\mathcal{B}))/\mathbb{C}^*$ acts by conjugation on the finite dimensional vector space $\mathcal{W} = \text{Hom}(\mathcal{A},\mathcal{B})$. Here, $\mathbb{C}^*$ is embedded as the subgroup of homotheties. The set of morphisms $\varphi$ appearing above is a locally closed subset $W \subset \mathcal{W}$, which is invariant under the action of $G$. We shall prove that a good or a categorical quotient of $W$ by $G$ exists and is isomorphic to $X$. The existence of the good quotient does not follow from the geometric invariant theory if $G$ is non-reductive, which, most of the time, will be our case. In some cases, we shall describe the sheaves in the strata by means of extensions.

Throughout this paper, we keep the notations and conventions from [4]. We work over the complex numbers. We fix a vector space $V$ over $\mathbb{C}$ of dimension 3 and we identify $\mathbb{P}^2$ with the space $\mathbb{P}(V)$ of lines in $V$. We fix a basis $\{X,Y,Z\}$ of $V^*$. If $\mathcal{A}$ and $\mathcal{B}$ are direct sums of line bundles on $\mathbb{P}^2$, we identify $\text{Hom}(\mathcal{A},\mathcal{B})$ with the space of matrices with entries in appropriate symmetric powers of $V^*$, that is, matrices with entries homogeneous polynomials in $X,Y,Z$. We especially refer to the section of preliminaries in [4], which contains most of the techniques that we shall use.

According to [10], there is a duality isomorphism $\mathcal{M}_{\mathbb{P}^2}(r,\chi) \simeq \mathcal{M}_{\mathbb{P}^2}(r,-\chi)$ sending the stable-equivalence class of a sheaf $\mathcal{F}$ to the stable-equivalence class of the dual sheaf $\mathcal{F}^\vee = \mathcal{E}xt^1(\mathcal{F},\omega_{\mathbb{P}^2})$. This allows us to study the spaces $\mathcal{M}_{\mathbb{P}^2}(5,\chi)$ in pairs. Thus $\mathcal{M}_{\mathbb{P}^2}(5,3)$ and $\mathcal{M}_{\mathbb{P}^2}(5,2)$ are isomorphic and will be studied in Section 2. The spaces $\mathcal{M}_{\mathbb{P}^2}(5,1)$ and $\mathcal{M}_{\mathbb{P}^2}(5,4)$ are, likewise, isomorphic and will be treated in Section 3. The last section deals with $\mathcal{M}_{\mathbb{P}^2}(5,0)$. In the remaining part of this introduction, we shall make a summary of results.

1.1. The moduli spaces $\mathcal{M}_{\mathbb{P}^2}(5,3)$ and $\mathcal{M}_{\mathbb{P}^2}(5,2)$. We shall decompose the moduli space $\mathcal{M}_{\mathbb{P}^2}(5,3)$ into four strata: an open stratum $X_0$, two locally closed strata $X_1,X_2$ and a closed stratum $X_3$. The stratum $X_1$ is a proper open subset inside a fibre bundle over $\mathbb{P}^2 \times N(3,2,3)$ with fibre $\mathbb{P}^1$. Here $N(3,2,3)$ is the moduli space of semi-stable Kronecker modules $\tau : \mathbb{C}^2 \otimes V \rightarrow \mathbb{C}^3$. Also, $X_2$ is a proper open subset inside a fibre bundle over $N(3,3,2)$ with fibre $\mathbb{P}^1$. The closed stratum $X_3$ is isomorphic to the Hilbert flag scheme of quintic curves in $\mathbb{P}^2$ containing zero-dimensional subschemes of length 2.

A sheaf $\mathcal{F}$ from $\mathcal{M}_{\mathbb{P}^2}(5,3)$ gives a point in $X_0$ if and only if the following cohomological conditions are satisfied:

$$h^0(\mathcal{F}(-1)) = 0, \quad h^1(\mathcal{F}) = 0, \quad h^0(\mathcal{F} \otimes \Omega^1(1)) = 1.$$
Each semi-stable sheaf whose stable-equivalence class is in $X_0$ has a resolution of the form

$$0 \rightarrow 2\mathcal{O}(-2) \oplus \mathcal{O}(-1) \xrightarrow{\varphi} 3\mathcal{O} \rightarrow \mathcal{F} \rightarrow 0.$$ 

We consider the vector space $\mathcal{W} = \text{Hom}(2\mathcal{O}(-2) \oplus \mathcal{O}(-1), 3\mathcal{O})$ and the linear algebraic group

$$G = (\text{Aut}(2\mathcal{O}(-2) \oplus \mathcal{O}(-1)) \times \text{Aut}(3\mathcal{O}))/\mathbb{C}^*$$

acting on $\mathcal{W}$ by conjugation. Here, $\mathbb{C}^*$ is embedded as the subgroup of homotheties. The set of morphisms $\varphi$ occurring above forms an open $G$-invariant subset $W \subset \mathcal{W}$ given by the following conditions: $\varphi$ is injective and $\varphi$ is not in the orbit of a morphism represented by a matrix of the form

$$\begin{bmatrix}
* & * & * \\
* & * & 0 \\
* & * & 0
\end{bmatrix} \quad \text{or} \quad \begin{bmatrix}
* & * & * \\
* & * & * \\
* & 0 & 0
\end{bmatrix}.$$ 

The set $W$ admits a geometric quotient $W/G$ modulo $G$ and $W/G \simeq X_0$. The information about $X_0$ is summarised in the second row of Table 1. The other rows of Table 1 contain the analogous information about the remaining strata of $M_{\mathbb{P}^2}(5, 3)$. The last column gives the codimension of each stratum. For each $W$, there is a geometric quotient $W/G$ modulo the canonical group $G$ acting by conjugation on the ambient vector space $\mathcal{W}$ of homomorphisms of sheaves and $W/G$ is isomorphic to the corresponding stratum of $M_{\mathbb{P}^2}(5, 3)$.

Applying to $X_i$ the duality isomorphism $M_{\mathbb{P}^2}(5, 3) \rightarrow M_{\mathbb{P}^2}(5, 2)$ of [10] defined by

$$\mathcal{F} \rightarrow \mathcal{F}^D(1) = \mathcal{E}xt^1(\mathcal{F}, \omega_{\mathbb{P}^2}) \otimes \mathcal{O}(1),$$

we get a dual stratum $X_i^D \subset M_{\mathbb{P}^2}(5, 2)$ given by the cohomological conditions derived from Serre duality (see Proposition 2.1.2 in [4]). For instance, $X_0^D$ consists of those sheaves $\mathcal{G}$ in $M_{\mathbb{P}^2}(5, 2)$ satisfying the conditions

$$h^1(\mathcal{G}) = 0, \quad h^0(\mathcal{G}(-1)) = 0, \quad h^1(\mathcal{G} \otimes \Omega^1(1)) = 1.$$ 

According to [10], Lemma 3, taking the dual of each term in a locally free resolution of length 1 for $\mathcal{F}$ gives a resolution for $\mathcal{F}^D$. Thus, every sheaf $\mathcal{G}$ in $X_0^D$ has a resolution of the form

$$0 \rightarrow 3\mathcal{O}(-2) \xrightarrow{\psi} \mathcal{O}(-1) \oplus 2\mathcal{O} \rightarrow \mathcal{G} \rightarrow 0.$$ 

The conditions on $\psi$ are the transposed conditions on the morphism $\varphi$ from above. In this fashion, we get a “dual table” for $M_{\mathbb{P}^2}(5, 2)$. We omit the details.

Inside $X_0$ there is an open dense subset of sheaves that have a presentation of the form

$$0 \rightarrow 2\mathcal{O}(-2) \rightarrow \Omega^1(2) \rightarrow \mathcal{F} \rightarrow 0.$$
Table 1. Summary for $M_{P^2}(5,3)$

| Stratum | Cohomological conditions | Subset $W \subset W$ of morphisms $\varphi$ | Codim. |
|---------|--------------------------|------------------------------------------|--------|
| $X_0$   | $h^0(\mathcal{F}(-1)) = 0$ | $2\mathcal{O}(-2) \oplus \mathcal{O}(-1) \xrightarrow{\varphi} 3\mathcal{O}$ | 0      |
|         | $h^1(\mathcal{F}) = 0$    | $\varphi$ is not equivalent to $\begin{bmatrix} * & * & * \\ * & 0 & * \\ * & 0 & 0 \end{bmatrix}$ or $\begin{bmatrix} * & * & * \\ * & 0 & * \\ * & 0 & 0 \end{bmatrix}$ |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 1$ | $\varphi$ is injective |        |
| $X_1$   | $h^0(\mathcal{F}(-1)) = 0$ | $2\mathcal{O}(-2) \oplus 2\mathcal{O}(-1) \xrightarrow{\varphi} \mathcal{O}(-1) \oplus 3\mathcal{O}$ | 2      |
|         | $h^1(\mathcal{F}) = 0$    | $\varphi$ is injective |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 2$ | $\varphi_{12} = 0$ |        |
|         |                           | $\varphi_{11}$ has linearly independent entries |        |
|         |                           | $\varphi_{22}$ has linearly independent maximal minors |        |
| $X_2$   | $h^0(\mathcal{F}(-1)) = 1$ | $3\mathcal{O}(-2) \xrightarrow{\varphi} 2\mathcal{O}(-1) \oplus \mathcal{O}(1)$ | 3      |
|         | $h^1(\mathcal{F}) = 0$    | $\varphi$ is injective |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 3$ | $\varphi_{11}$ has linearly independent maximal minors |        |
| $X_3$   | $h^0(\mathcal{F}(-1)) = 1$ | $\mathcal{O}(-3) \oplus \mathcal{O}(-1) \xrightarrow{\varphi} \mathcal{O} \oplus \mathcal{O}(1)$ | 4      |
|         | $h^1(\mathcal{F}) = 1$    | $\varphi$ is injective |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 4$ | $\varphi_{12} \neq 0$ |        |
|         |                           | $\varphi_{12} \uparrow \varphi_{22}$ |        |

The complement in $X_0$ of this subset, denoted $X_{01}$, has codimension 1. The generic sheaves giving points in $X_{01}$ have the form

$$\mathcal{O}_C(1)(P_1 + P_2 + P_3 + P_4 - P_5),$$

where $C \subset \mathbb{P}^2$ is a smooth quintic curve, and $P_1, \ldots, P_5$ are distinct points on $C$ and $P_1, P_2, P_3, P_4$ are in general linear position.

The sheaves giving points in $X_1$ are precisely the non-split extension sheaves of the form

$$0 \rightarrow \mathcal{G} \rightarrow \mathcal{F} \rightarrow \mathcal{C}_x \rightarrow 0,$$

satisfying $H^1(\mathcal{F}) = 0$, where $\mathcal{G}$ varies in $X^p_2$ and $\mathcal{C}_x$ is the structure sheaf of a closed point in the support of $\mathcal{G}$.

The sheaves $\mathcal{G}$ in $X^p_2$ are either of the form $\mathcal{J}_Z(2)$, where $\mathcal{J}_Z \subset \mathcal{O}_C$ is the ideal sheaf of a zero-dimensional subscheme of length 3 contained in a quintic.
curve $C$, $Z$ not contained in a line, or they are extension sheaves of the form
\[ 0 \longrightarrow \mathcal{O}_L(-1) \longrightarrow \mathcal{G} \longrightarrow \mathcal{O}_D(1) \longrightarrow 0, \]
where $L$ is a line and $D$ is a quartic curve, that are not in the kernel of the canonical map
\[ \text{Ext}^1(\mathcal{O}_D(1), \mathcal{O}_L(-1)) \longrightarrow \text{Ext}^1(\mathcal{O}(1), \mathcal{O}_L(-1)). \]

The sheaves in $X_3$ are the twisted ideal sheaves $\mathcal{J}_Z(2) \subset \mathcal{O}_C$ of zero-dimensional subschemes $Z$ of length 2 contained in quintic curves $C$.

1.2. The moduli spaces $\text{M}_{\mathbb{P}^2}(5, 1)$ and $\text{M}_{\mathbb{P}^2}(5, 4)$. We shall decompose the moduli space $\text{M}_{\mathbb{P}^2}(5, 1)$ into four strata: an open stratum $X_0$, two locally closed strata $X_1, X_2$ and a closed stratum $X_3$. The stratum $X_0$ is a proper open subset inside a fibre bundle with base $N(3, 4, 3)$ and fibre $\mathbb{P}^{14}$. The stratum $X_1$ is a proper open subset inside a fibre bundle with base $\text{Grass}(2, \mathbb{C}^6)$ and fibre $\mathbb{P}^{16}$. Also, $X_2$ is a proper open subset inside a fibre bundle with fibre $\mathbb{P}^{17}$ and base $Y \times \mathbb{P}^2$, where $Y$ is the Hilbert scheme of zero-dimensional subschemes of $\mathbb{P}^2$ of length 2. The stratum $X_3$ is the universal quintic in $\mathbb{P}^2 \times \mathbb{P}(S^5V^*)$.

The information about the cohomological conditions defining each stratum in $\text{M}_{\mathbb{P}^2}(5, 1)$ and resolutions for semi-stable sheaves can be found in Table 2 below. This is organised as Table 1, so we refer to the previous subsection for the meaning of the different items. Again, each $X_i$ is isomorphic to the corresponding geometric quotient $W/G$. By duality, from Table 2 can be obtained a table for $\text{M}_{\mathbb{P}^2}(5, 4)$, which we do not include here.

Inside $X_0$ there is an open dense subset consisting of sheaves of the form $\mathcal{J}_Z(2)^{\mathbb{D}}$, where $Z \subset \mathbb{P}^2$ is a zero-dimensional scheme of length 6 not contained in a conic curve, contained in a quintic curve $C$, and $\mathcal{J}_Z \subset \mathcal{O}_C$ is its ideal sheaf. The complement in $X_0$ of this open subset is the disjoint union of two sets $X_{01}$ and $X_{02}$. The sheaves in $X_{01}$ occur as non-split extensions of one of the following three kinds:
\[ 0 \longrightarrow \mathcal{G} \longrightarrow \mathcal{F} \longrightarrow \mathcal{O}_L \longrightarrow 0, \]
\[ 0 \longrightarrow \mathcal{E} \longrightarrow \mathcal{F} \longrightarrow \mathcal{O}_Y \longrightarrow 0, \]
\[ 0 \longrightarrow \mathcal{O}_L(-1) \longrightarrow \mathcal{F} \longrightarrow \mathcal{J}_Z(1)^{\mathbb{D}} \longrightarrow 0. \]

Here $L \subset \mathbb{P}^2$ is a line, $\mathcal{G}$ is in the exceptional divisor of $\text{M}_{\mathbb{P}^2}(4, 0)$, $\mathcal{E}$ is the twist by $-1$ of a sheaf in the stratum $X_3 \subset \text{M}_{\mathbb{P}^2}(5, 3)$, $Y \subset \mathbb{P}^2$ is a zero-dimensional scheme of length 3 not contained in a line, contained in the support of $\mathcal{E}$, $Z \subset \mathbb{P}^2$ is a zero-dimensional scheme of length 3 not contained in a line, contained in a quartic curve $C$, and $\mathcal{J}_Z \subset \mathcal{O}_C$ is its ideal sheaf. Not all of the above extension sheaves are in $X_{01}$, namely there are certain conditions that must be satisfied for which we refer to Section 3.3. For $X_{02}$ we can be more specific. A sheaf $\mathcal{F}$ gives a point in $X_{02}$ precisely if it is an extension of the form
\[ 0 \longrightarrow \mathcal{O}_C' \longrightarrow \mathcal{F} \longrightarrow \mathcal{O}_C \longrightarrow 0 \]
Table 2. Summary for $\mathcal{M}_{\mathbb{P}^2}(5, 1)$

| Stratum | Cohomological conditions | Subset $W \subset \mathbb{W}$ of morphisms $\varphi$ | Codim. |
|---------|--------------------------|--------------------------------------------------|--------|
| $X_0$   | $h^0(\mathcal{F}(-1)) = 0$ | $4\mathcal{O}(-2) \xrightarrow{\varphi} 3\mathcal{O}(-1) \oplus \mathcal{O}$ | 0      |
|         | $h^1(\mathcal{F}) = 0$    | $\varphi$ is injective                           |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 0$ | $\varphi_{11}$ is not equivalent to $\begin{bmatrix} * & * & * & 0 \\ * & * & * & 0 \\ * & * & 0 & 0 \\ * & * & * & * \end{bmatrix}$ or $\begin{bmatrix} * & 0 & 0 & 0 \\ * & * & * & * \\ * & * & * & * \\ * & * & * & * \end{bmatrix}$ |        |
| $X_1$   | $h^0(\mathcal{F}(-1)) = 0$ | $\mathcal{O}(-3) \oplus \mathcal{O}(-2) \xrightarrow{\varphi} 2\mathcal{O}$ | 2      |
|         | $h^1(\mathcal{F}) = 1$    | $\varphi$ is injective                           |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 0$ | $\varphi_{12}$ and $\varphi_{22}$ are linearly independent two-forms |        |
| $X_2$   | $h^0(\mathcal{F}(-1)) = 0$ | $\mathcal{O}(-3) \oplus \mathcal{O}(-2) \oplus \mathcal{O}(-1) \xrightarrow{\varphi} \mathcal{O}(-1) \oplus 2\mathcal{O}$ | 3      |
|         | $h^1(\mathcal{F}) = 1$    | $\varphi$ is injective                           |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 1$ | $\varphi_{13} = 0$ and $\varphi_{12} \not\parallel \varphi_{11}$ $\varphi_{23}$ has linearly independent entries |        |
| $X_3$   | $h^0(\mathcal{F}(-1)) = 1$ | $2\mathcal{O}(-3) \xrightarrow{\varphi} \mathcal{O}(-2) \oplus \mathcal{O}(1)$ | 5      |
|         | $h^1(\mathcal{F}) = 2$    | $\varphi$ is injective                           |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 3$ | $\varphi_{11}$ has linearly independent entries |        |

and satisfies $H^1(\mathcal{F}) = 0$. Here $C'$ is a cubic curve, $C$ is a conic curve in $\mathbb{P}^2$.

The sheaves $\mathcal{F}$ in $X_1$ are either of the form $\mathcal{J}_Z(2)$, where $Z \subset \mathbb{P}^2$ is the intersection of two conic curves without common component, $Z$ is contained in a quintic curve $C$ and $\mathcal{J}_Z \subset \mathcal{O}_C$ is its ideal sheaf, or they are extension sheaves of the form

$$0 \longrightarrow \mathcal{O}_L(-1) \longrightarrow \mathcal{F} \longrightarrow \mathcal{J}_x(1) \longrightarrow 0,$$

satisfying the condition $H^0(\mathcal{F} \otimes \Omega^1(1)) = 0$. Here $L \subset \mathbb{P}^2$ is a line and $\mathcal{J}_x \subset \mathcal{O}_{C'}$ is the ideal sheaf of a closed point $x$ on a quartic curve $C' \subset \mathbb{P}^2$.

The generic sheaves from $X_2$ are of the form $\mathcal{O}_C(1)(-P_1 + P_2 + P_3)$, where $C \subset \mathbb{P}^2$ is a smooth quintic curve and $P_1, P_2, P_3$ are distinct points on $C$.

The sheaves giving points in $X_3$ are precisely the non-split extension sheaves of the form

$$0 \longrightarrow \mathcal{O}_C(1) \longrightarrow \mathcal{F} \longrightarrow \mathbb{C}_x \longrightarrow 0.$$
Here $C \subset \mathbb{P}^2$ is a quintic curve and $C_x$ is the structure sheaf of a closed point.

1.3. The moduli space $\mathcal{M}_{\mathbb{P}^2}(5,0)$. This moduli space can be decomposed into four strata: an open stratum $X_0$, two locally closed strata $X_1, X_2$ and a closed stratum $X_3$. The stratum $X_0$ is a proper open subset inside $\mathcal{N}(3,5,5)$. Also, $X_2$ is a proper open subset inside a fibre bundle over $\mathbb{P}^2 \times \mathbb{P}^2$ with fibre $\mathbb{P}^{18}$. The closed stratum $X_3$ consists of sheaves of the form $\mathcal{O}_C(1)$, where $C \subset \mathbb{P}^2$ is a quintic curve, and is isomorphic to $\mathbb{P}(S^5V^*)$. All strata are invariant under the duality isomorphism.

The information about the cohomological conditions defining each stratum and resolutions for semi-stable sheaves can be found in Table 3 below, which is organised as Table 1. We will show that $X_0$ is a good quotient, $X_1$ is a categorical quotient and $X_2$ is a geometric quotient of $W$ by $G$.

The generic sheaves in $X_0$ are of the form $\mathcal{J}_Z(3)$, where $Z \subset \mathbb{P}^2$ is a zero-dimensional scheme of length 10 not contained in a cubic curve, contained in a quintic curve $C$, and $\mathcal{J}_Z \subset \mathcal{O}_C$ is its ideal sheaf.

The sheaves giving points in $X_2$ are precisely the non-split extension sheaves of the form

$$0 \rightarrow \mathcal{J}_x(1) \rightarrow \mathcal{F} \rightarrow \mathcal{O}_C(1) \rightarrow 0,$$

where $\mathcal{J}_x \subset \mathcal{O}_C$ is the ideal sheaf of a closed point $x$ on a quintic curve $C \subset \mathbb{P}^2$ and $\mathcal{O}_C$ is the structure sheaf of a closed point $z \in C$. When $x = z$ we exclude the possibility $\mathcal{F} \simeq \mathcal{O}_C(1)$.

| Stratum | Cohomological conditions | Subset $W \subset \mathbb{W}$ of morphisms $\varphi$ | Codim. |
|---------|--------------------------|---------------------------------------------------|--------|
| $X_0$   | $h^0(\mathcal{F}(-1)) = 0$ | $5\mathcal{O}(-2) \xrightarrow{\varphi} 5\mathcal{O}(-1)$ | 0      |
|         | $h^1(\mathcal{F}) = 0$    | $\varphi$ is injective                             |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 0$ |                                                |        |
| $X_1$   | $h^0(\mathcal{F}(-1)) = 0$ | $\mathcal{O}(-3) \oplus 2\mathcal{O}(-2) \xrightarrow{\varphi} 2\mathcal{O}(-1) \oplus \mathcal{O}$ | 1      |
|         | $h^1(\mathcal{F}) = 1$    | $\varphi$ is injective                             |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 0$ | $\varphi_{12}$ is injective                        |        |
| $X_2$   | $h^0(\mathcal{F}(-1)) = 0$ | $2\mathcal{O}(-3) \oplus \mathcal{O}(-1) \xrightarrow{\varphi} \mathcal{O}(-2) \oplus 2\mathcal{O}$ | 4      |
|         | $h^1(\mathcal{F}) = 2$    | $\varphi$ is injective                             |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 1$ | $\varphi_{11}$ has linearly independent entries $\varphi_{22}$ has linearly independent entries |        |
| $X_3$   | $h^0(\mathcal{F}(-1)) = 1$ | $\mathcal{O}(-4) \xrightarrow{\varphi} \mathcal{O}(1)$ | 6      |
|         | $h^1(\mathcal{F}) = 3$    | $\varphi \neq 0$                                  |        |
|         | $h^0(\mathcal{F} \otimes \Omega^1(1)) = 3$ |                                                |        |
2. Euler characteristic two or three

2.1. Locally free resolutions for semi-stable sheaves.

**Proposition 2.1.1.** There are no sheaves $F$ giving points in $\mathbb{P}^2(5,3)$ and satisfying the conditions $h^0(F(-1)) = 0$ and $h^1(F) \neq 0$.

**Proof.** According to Claim 6.4 in [9], there are no sheaves $G$ in $\mathbb{P}^2(5,2)$ satisfying the conditions $h^0(G(-1)) \neq 0$ and $h^1(G) = 0$. The result follows by duality. □

From this and from Claim 4.3 in [9] we obtain the following.

**Proposition 2.1.2.** Let $F$ be a sheaf in $\mathbb{P}^2(5,3)$ satisfying the condition $h^0(F(-1)) = 0$. Then $h^1(F) = 0$ and $h^0(F \otimes \Omega^1(1)) = 1$ or 2. The sheaves from the first case are precisely the sheaves that have a resolution of the form

(i) \[ 0 \rightarrow 2\mathcal{O}(-2) \oplus \mathcal{O}(-1) \xrightarrow{\varphi} 3\mathcal{O} \rightarrow F \rightarrow 0 \]

with $\varphi$ not equivalent, modulo the action of the natural group of automorphisms, to a morphism represented by a matrix of the form

\[
\begin{bmatrix}
* & * & * \\
* & * & 0 \\
* & 0 & 0
\end{bmatrix} \quad \text{or} \quad
\begin{bmatrix}
* & * & * \\
* & * & 0 \\
0 & 0 & 0
\end{bmatrix}.
\]

The sheaves in the second case are precisely the sheaves that have a resolution of the form

(ii) \[ 0 \rightarrow 2\mathcal{O}(-2) \oplus 2\mathcal{O}(-1) \xrightarrow{\varphi} \mathcal{O}(-1) \oplus 3\mathcal{O} \rightarrow F \rightarrow 0, \]

where $\varphi_{11}$ has linearly independent maximal minors.

**Proposition 2.1.3.** Let $F$ be a sheaf giving a point in $\mathbb{P}^2(5,3)$ and satisfying the conditions $h^1(F) = 0$ and $h^0(F(-1)) \neq 0$. Then $h^0(F(-1)) = 1$. These sheaves are precisely the sheaves with resolution of the form

\[ 0 \rightarrow 3\mathcal{O}(-2) \xrightarrow{\varphi} 2\mathcal{O}(-1) \oplus \mathcal{O}(1) \rightarrow F \rightarrow 0, \]

where $\varphi_{11}$ has linearly independent maximal minors.

**Proof.** The first conclusion follows from Claim 6.6 in [9]. According to Claim 5.3 in [9], every sheaf $G$ in $\mathbb{P}^2(5,2)$ satisfying $h^0(G(-1)) = 0$ and $h^1(G) = 1$ has a resolution

\[ 0 \rightarrow \mathcal{O}(-3) \oplus 2\mathcal{O}(-1) \xrightarrow{\psi} 3\mathcal{O} \rightarrow G \rightarrow 0 \]

in which $\psi_{12}$ has linearly independent maximal minors. The second conclusion follows by duality. □
Proposition 2.1.4. Let $\mathcal{F}$ be a sheaf giving a point in $\mathbb{M}_{\mathbb{P}^2}(5, 3)$ and satisfying the conditions $h^0(\mathcal{F}(-1)) = 1$ and $h^1(\mathcal{F}) = 1$. Then $h^0(\mathcal{F} \otimes \Omega^1(1)) = 4$ and $\mathcal{F}$ has a resolution of the form

$$0 \to \mathcal{O}(-3) \oplus \mathcal{O}(-1) \xrightarrow{\varphi} \mathcal{O} \oplus \mathcal{O}(1) \to \mathcal{F} \to 0$$

with $\varphi_{12} \neq 0$ and $\varphi_{22}$ not divisible by $\varphi_{12}$. Conversely, every $\mathcal{F}$ having such a resolution is semi-stable.

Proof. Let $\mathcal{F}$ give a point in $\mathbb{M}_{\mathbb{P}^2}(5, 3)$ and satisfy the cohomological conditions from the claim. Write $m = h^0(\mathcal{F} \otimes \Omega^1(1))$. The Beilinson free monad (2.2.1) in [4] for $\mathcal{F}$ reads

$$0 \to \mathcal{O}(-2) \to 3\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \to (m - 1)\mathcal{O}(-1) \oplus 4\mathcal{O} \to \mathcal{O} \to 0$$

and gives the resolution

$$0 \to \mathcal{O}(-2) \to 3\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \to \Omega^1 \oplus (m - 4)\mathcal{O}(-1) \oplus 4\mathcal{O} \to \mathcal{F} \to 0.$$ 

We see from the above that $m \geq 4$. Combining with the Euler sequence, we obtain the resolution

$$0 \to \mathcal{O}(-2) \xrightarrow{\psi} \mathcal{O}(-3) \oplus 3\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \xrightarrow{\varphi} 3\mathcal{O}(-2) \oplus (m - 4)\mathcal{O}(-1) \oplus 4\mathcal{O} \to \mathcal{F} \to 0,$$

where

$$\psi = \begin{bmatrix} 0 \\ 0 \\ \psi_{31} \end{bmatrix}, \quad \varphi = \begin{bmatrix} \eta & \varphi_{12} & 0 \\ 0 & \varphi_{22} & 0 \\ 0 & \varphi_{32} & \varphi_{33} \end{bmatrix}.$$ 

Here

$$\eta = \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}.$$ 

We have a commutative diagram in which the vertical maps are projections onto direct summands:

$$\begin{array}{ccc}
\mathcal{O}(-3) \oplus 3\mathcal{O}(-2) \oplus m\mathcal{O}(-1) & \xrightarrow{\varphi} & 3\mathcal{O}(-2) \oplus (m - 4)\mathcal{O}(-1) \oplus 4\mathcal{O} \\
\downarrow & & \downarrow \\
\mathcal{O}(-3) \oplus 3\mathcal{O}(-2) & \xrightarrow{\alpha} & 3\mathcal{O}(-2)
\end{array}$$

$$\alpha = \begin{bmatrix} \eta & \varphi_{12} \end{bmatrix}.$$ 

Thus, $\mathcal{F}$ maps surjectively to $\text{Coker}(\alpha)$. If $\text{rank}(\varphi_{12}) = 0$, then $\text{Coker}(\alpha) \simeq \Omega^1$. If $\text{rank}(\varphi_{12}) = 1$, then $\text{Coker}(\alpha) \simeq \mathcal{I}_x(-1)$, where $\mathcal{I}_x \subset \mathcal{O}$ is the ideal sheaf of a point $x \in \mathbb{P}^2$. These two cases are unfeasible because $\mathcal{F}$ has support of dimension 1 so it cannot map surjectively onto a sheaf supported on the entire plane. If $\text{rank}(\varphi_{12}) = 2$, then $\text{Coker}(\alpha)$ would be isomorphic to $\mathcal{O}_L(-2)$ for a
line $L \subset \mathbb{P}^2$, so it would destabilise $F$. We conclude that $\text{rank}(\varphi_{12}) = 3$. We may cancel $3\mathcal{O}(-2)$ to get the resolution

$$0 \longrightarrow \mathcal{O}(-2) \xrightarrow{\psi} \mathcal{O}(-3) \oplus m\mathcal{O}(-1) \xrightarrow{\varphi} (m - 4)\mathcal{O}(-1) \oplus 4\mathcal{O} \longrightarrow F \longrightarrow 0,$$

$$\psi = \begin{bmatrix} 0 \\ \psi_{21} \end{bmatrix}, \quad \varphi = \begin{bmatrix} \varphi_{11} & 0 \\ \varphi_{21} & \varphi_{22} \end{bmatrix}. $$

Note that $F$ maps surjectively onto $\text{Coker}(\varphi_{11})$, so the latter has rank zero, forcing $m \leq 5$. If $m = 5$, then $\text{Coker}(\varphi_{11})$ would be isomorphic to $\mathcal{O}_C(-1)$ for a conic curve $C \subset \mathbb{P}^2$, so it would destabilise $F$. We deduce that $m = 4$ and we get the resolution

$$0 \longrightarrow \mathcal{O}(-2) \xrightarrow{\psi} \mathcal{O}(-3) \oplus 4\mathcal{O}(-1) \xrightarrow{\varphi} 4\mathcal{O} \longrightarrow F \longrightarrow 0.$$ 

Let $\bar{\psi} : V \to \mathbb{C}^4$ be the linear map induced by $\psi_{21}$. Let $H$ be the image of $\bar{\psi}$ and let $K \subset \mathbb{C}^4$ be a linear subspace such that $H \oplus K = \mathbb{C}^4$. We have an exact sequence

$$0 \longrightarrow \mathcal{O}(-2) \xrightarrow{\psi} \mathcal{O}(-3) \oplus (K \otimes \mathcal{O}(-1)) \oplus (H \otimes \mathcal{O}(-1)) \xrightarrow{\varphi} 4\mathcal{O} \longrightarrow F \longrightarrow 0,$$

in which $\psi_{11} = 0$, $\psi_{21} = 0$. If $\dim(H) = 1$, then $\psi_{31}$ is generically surjective. If $\varphi$ vanishes on $\text{Im}(\psi_{31})$, it must vanish on $H \otimes \mathcal{O}(-1)$, hence $H \otimes \mathcal{O}(-1)$ is a subsheaf of $\mathcal{O}(-2)$. This is absurd. If $\dim(H) = 2$, then $\text{Coker}(\psi_{31})$ is isomorphic to the ideal sheaf $\mathcal{I}_x$ of a point $x \in \mathbb{P}^2$. We get a resolution

$$0 \longrightarrow \mathcal{O}(-3) \oplus 2\mathcal{O}(-1) \oplus \mathcal{I}_x \longrightarrow 4\mathcal{O} \longrightarrow F \longrightarrow 0.$$ 

The image of $\mathcal{I}_x$ is included into a factor $\mathcal{O}$ of $4\mathcal{O}$ because $\text{Hom}(\mathcal{I}_x, \mathcal{O}) \simeq \mathbb{C}$. We obtain a commutative diagram

$$\begin{array}{cccc}
0 & \longrightarrow & \mathcal{I}_x & \longrightarrow & \mathcal{O} & \longrightarrow & \mathbb{C}_x & \longrightarrow & 0 \\
\downarrow & & \downarrow & & & & \downarrow & & \\
0 & \longrightarrow & \mathcal{O}(-3) \oplus 2\mathcal{O}(-1) \oplus \mathcal{I}_x & \longrightarrow & 4\mathcal{O} & \longrightarrow & F & \longrightarrow & 0
\end{array}$$

in which the first two vertical maps are injective. The induced map $\mathbb{C}_x \to F$ is zero because $F$ has no zero-dimensional torsion. It follows that $\mathcal{O}$ is a subsheaf of $\mathcal{O}(-3) \oplus 2\mathcal{O}(-1) \oplus \mathcal{I}_x$, which is absurd. We deduce that $H$ has dimension 3, so $\text{Coker}(\psi_{31}) \simeq \Omega^1(1)$ and we get the resolution

$$0 \longrightarrow \mathcal{O}(-3) \oplus \mathcal{O}(-1) \oplus \Omega^1(1) \xrightarrow{\varphi} 4\mathcal{O} \longrightarrow F \longrightarrow 0.$$ 

Consider the canonical morphism $i : \Omega^1(1) \to \text{Hom}(\Omega^1(1), \mathcal{O})^* \otimes \mathcal{O} \simeq 3\mathcal{O}$. There is a morphism $\beta : 3\mathcal{O} \to 4\mathcal{O}$ such that $\beta \circ i = \varphi_{13}$. If $\beta$ were not injective, then $\varphi$ would be equivalent to a morphism represented by a matrix of the form

$$\begin{bmatrix} \gamma_{11} & 0 \\ \gamma_{21} & \gamma_{22} \end{bmatrix},$$
where \( \gamma_{11} \in \text{Hom}(\mathcal{O}(-3) \oplus \mathcal{O}(-1), 2\mathcal{O}) \). But then \( \text{Coker}(\gamma_{11}) \) would be a destabilising quotient sheaf of \( \mathcal{F} \). Thus \( \beta \) is injective, from which we deduce that \( \text{Coker}(\varphi_{13}) \simeq \mathcal{O} \oplus \mathcal{O}(1) \). We obtain the resolution
\[
0 \longrightarrow \mathcal{O}(-3) \oplus \mathcal{O}(-1) \longrightarrow \mathcal{O} \oplus \mathcal{O}(1) \longrightarrow \mathcal{F} \longrightarrow 0.
\]
If \( \varphi_{12} = 0 \), then \( \mathcal{F} \) would have a destabilising subsheaf of the form \( \mathcal{O}_C(1) \), for a conic curve \( C \subset \mathbb{P}^2 \). If \( \varphi_{12} \) divided \( \varphi_{22} \), then \( \mathcal{F} \) would have a destabilising subsheaf of the form \( \mathcal{O}_L \) for a line \( L \subset \mathbb{P}^2 \).

Conversely, assume that \( \mathcal{F} \) has a resolution as in the claim. Then \( \mathcal{F} \) has no zero-dimensional torsion because it has projective dimension 1 at every point in its support. Thus, it is enough to show that \( \mathcal{F} \) cannot have a destabilising subsheaf. Let \( \mathcal{F}' \subset \mathcal{F} \) be a non-zero subsheaf of multiplicity at most 4. According to Proposition 2.3.5, \( \mathcal{F} \) is isomorphic to \( \mathcal{J}_Z(2) \), where \( \mathcal{J}_Z \subset \mathcal{O}_C \) is the ideal sheaf of a zero-dimensional scheme \( Z \) of length 2 inside a quintic curve \( C \).

According to [9], Lemma 6.7, there is a sheaf \( \mathcal{A} \subset \mathcal{O}_C(2) \) containing \( \mathcal{F}' \) such that \( \mathcal{A}/\mathcal{F}' \) is supported on finitely many points and \( \mathcal{O}_C(2)/\mathcal{A} \simeq \mathcal{O}_S(2) \) for a curve \( S \subset C \) of degree \( d \leq 4 \). The slope of \( \mathcal{F}' \) can be estimated as follows:
\[
P_{\mathcal{F}'}(t) = P_{\mathcal{A}}(t) - h^0(\mathcal{A}/\mathcal{F}')
= P_{\mathcal{O}_C}(t+2) - P_{\mathcal{O}_S}(t+2) - h^0(\mathcal{A}/\mathcal{F}')
= (5-d)t + \frac{(d-5)(d-2)}{2} - h^0(\mathcal{A}/\mathcal{F}'),
\]
\[
p(\mathcal{F}') = \frac{2-d}{2} - \frac{h^0(\mathcal{A}/\mathcal{F}')}{{5-d}} \leq \frac{1}{2} < \frac{3}{5} = p(\mathcal{F}).
\]

We conclude that \( \mathcal{F} \) is semi-stable. \( \square \)

**Proposition 2.1.5.** Any sheaf \( \mathcal{G} \) giving a point in \( \text{M}_{\mathbb{P}^2}(5,2) \) satisfies the condition \( h^0(\mathcal{G}(-1)) \leq 1 \).

**Proof.** Let \( \mathcal{G} \) be in \( \text{M}_{\mathbb{P}^2}(5,2) \) and assume that \( h^0(\mathcal{G}(-1)) > 0 \). As in the proof of Proposition 2.1.3 in [4], there is an injective morphism \( \mathcal{O}_C \rightarrow \mathcal{G}(-1) \) for a curve \( C \subset \mathbb{P}^2 \). From the semi-stability of \( \mathcal{G}(-1) \), we see that \( C \) must be a quintic curve. The quotient sheaf \( \mathcal{G}(-1)/\mathcal{O}_C \) is a sheaf of dimension zero and length 2; it maps surjectively onto the structure sheaf \( \mathbb{C}_x \) of a point \( x \). Let \( \mathcal{G}' \) be the kernel of the composed morphism \( \mathcal{G} \rightarrow \mathbb{C}_x \). If \( \mathcal{G}' \) is semi-stable, then, from Proposition 3.1.5, we have \( h^0(\mathcal{G}'(-1)) \leq 1 \). It follows that \( h^0(\mathcal{G}(-1)) \leq 1 \) unless \( h^0(\mathcal{G}'(-1)) = 1 \) and the morphism \( \mathcal{G}(-1) \rightarrow \mathbb{C}_x \) is surjective on global sections. In this case, we can apply the horseshoe lemma to the extension
\[
0 \longrightarrow \mathcal{G}'(-1) \longrightarrow \mathcal{G}(-1) \longrightarrow \mathbb{C}_x \longrightarrow 0,
\]
to the standard resolution of \( \mathbb{C}_x \) and to resolution in Proposition 3.1.5 for \( \mathcal{G}' \) tensored with \( \mathcal{O}(-1) \), which reads:
\[
0 \longrightarrow 2\mathcal{O}(-4) \longrightarrow \mathcal{O}(-3) \oplus \mathcal{O} \longrightarrow \mathcal{G}'(-1) \longrightarrow 0.
\]
We get a resolution of the form

$$0 \rightarrow 2\mathcal{O}(-4) \oplus \mathcal{I}_x \rightarrow \mathcal{O}(-3) \oplus 2\mathcal{O} \rightarrow \mathcal{G}(-1) \rightarrow 0.$$ 

We now arrive at a contradiction as in the proof of Proposition 2.1.4. The image of $\mathcal{I}_x$ is included in a factor $\mathcal{O}$ of $2\mathcal{O}$. As $\mathcal{G}(-1)$ has no zero-dimensional torsion, this factor $\mathcal{O}$ maps to zero in $\mathcal{G}(-1)$, which is absurd.

Assume now that $\mathcal{G}'$ is not semi-stable and let $\mathcal{G}'' \subset \mathcal{G}'$ be a destabilising subsheaf. We may assume that $\mathcal{G}''$ itself is semi-stable, say it gives a point in $M_{\mathbb{P}^2}(r, \chi)$. We have the inequalities

$$\frac{1}{5} = p(\mathcal{G}') < \frac{\chi}{r} < p(\mathcal{G}) = \frac{2}{5},$$

leaving only the possibilities $(r, \chi) = (4, 1)$ or $(3, 1)$. Denote $C = \mathcal{G}/\mathcal{G}''$. If $\mathcal{G}''$ is in $M_{\mathbb{P}^2}(4, 1)$, then $P_C(t) = t + 1$. Moreover, the zero-dimensional torsion of $C$ vanishes, otherwise its pull-back in $\mathcal{G}$ would be a destabilising subsheaf. We deduce that $C = \mathcal{O}_L$ for a line $L \subset \mathbb{P}^2$. But $h^0(\mathcal{O}_L(-1)) = 0$ and, according to Proposition 2.1.3 in [4], also $h^0(\mathcal{G}''(-1)) = 0$. We get $h^0(\mathcal{G}(-1)) = 0$, contradicting our hypothesis on $\mathcal{G}$.

The last case to examine is when $\mathcal{G}''$ is in $M_{\mathbb{P}^2}(3, 1)$. We have $P_C(t) = 2t + 1$. As before, $C$ has no zero-dimensional torsion. Moreover, any quotient sheaf destabilising $C$ must also destabilise $\mathcal{G}$. We conclude that $C$ is semi-stable, i.e. $C = \mathcal{O}_C$ for a conic curve $C \subset \mathbb{P}^2$. But $h^0(\mathcal{O}_C(-1)) = 0$ and, according to Proposition 2.1.3 in [4], also $h^0(\mathcal{G}''(-1)) = 0$. We conclude that $h^0(\mathcal{G}(-1)) = 0$, contrary to our hypothesis on $\mathcal{G}$. \hfill $\Box$

**Proposition 2.1.6.** There are no sheaves $\mathcal{G}$ giving points in $M_{\mathbb{P}^2}(5, 2)$ and satisfying the conditions $h^0(\mathcal{G}(-1)) = 1$ and $h^1(\mathcal{G}) \geq 2$.

**Proof.** Fix an integer $m \geq 0$ and let $X$ be the set of sheaves $\mathcal{G}$ in $M_{\mathbb{P}^2}(5, 2)$ satisfying $h^0(\mathcal{G}(-1)) = 1$ and $h^0(\mathcal{G} \otimes \Omega^1) = m$. Let $Y \subset X$ be the subset of sheaves satisfying the additional condition $h^1(\mathcal{G}) = 1$. According to Proposition 2.1.3 in [4], for every sheaf in $X$ we have $H^0(\mathcal{G}(-2)) = 0$. The Beilinson free monad (2.2.1) in [4] for $\mathcal{G}(-1)$ reads

$$0 \rightarrow 8\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \rightarrow (m + 11)\mathcal{O}(-1) \oplus \mathcal{O} \rightarrow 4\mathcal{O} \rightarrow 0.$$ 

Thus, $X$ is parametrised by an open subset $M$ inside the space of monads of the form

$$0 \rightarrow 8\mathcal{O}(-1) \oplus m\mathcal{O} \xrightarrow{A} (m + 11)\mathcal{O} \oplus \mathcal{O}(1) \xrightarrow{B} 4\mathcal{O}(1) \rightarrow 0,$$

where $A_{12} = 0$, $B_{12} = 0$. Let $\Gamma$ be the space of pairs $(A, B)$ of morphisms

$$A \in \text{Hom}(8\mathcal{O}(-1) \oplus m\mathcal{O}, (m + 11)\mathcal{O} \oplus \mathcal{O}(1)),$$

$$B \in \text{Hom}((m + 11)\mathcal{O} \oplus \mathcal{O}(1), 4\mathcal{O}(1)),$$

such that $A$ is injective, $B$ is surjective, $A_{12} = 0$, $B_{12} = 0$. Consider the algebraic map $\gamma : \Gamma \rightarrow \text{Hom}(8\mathcal{O}(-1), 4\mathcal{O}(1))$ given by $\gamma(A, B) = B_{11} \circ A_{11}$.
Note that $M$ is an open subset inside $\gamma^{-1}(0)$. We claim that $M$ is smooth. For this, it is sufficient to show that $\gamma$ has surjective differential at every point of $M$. The tangent space of $\Gamma$ at an arbitrary point $(A,B)$ is the space of pairs $(\alpha, \beta)$ of morphisms
\[
\alpha \in \text{Hom}(8\mathcal{O}(-1) \oplus m\mathcal{O}, (m+11)\mathcal{O} \oplus \mathcal{O}(1)), \\
\beta \in \text{Hom}((m+11)\mathcal{O} \oplus \mathcal{O}(1), 4\mathcal{O}(1)),
\]
such that $\alpha_{12} = 0, \beta_{12} = 0$. We have $d\gamma_{(A,B)}(\alpha, \beta) = B_{11} \circ \alpha_{11} + \beta_{11} \circ A_{11}$. It is enough to prove that the map $\alpha_{11} \to B_{11} \circ \alpha_{11}$ is surjective at a point $(A,B) \in M$. For this, we apply the long Ext-sequence to the exact sequence
\[
0 \to \text{Ker}(B_{11}) \to (m+11)\mathcal{O} \to B_{11} \to 4\mathcal{O}(1) \to 0
\]
and we use the vanishing of $\text{Ext}^1(8\mathcal{O}(-1), \text{Ker}(B_{11}))$. This vanishing follows from the exact sequence
\[
0 \to 8\mathcal{O}(-1) \oplus m\mathcal{O} \to \text{Ker}(B_{11}) \oplus \mathcal{O}(1) \to \mathcal{G} \to 0
\]
and the vanishing of $H^1(\mathcal{G}(1))$, which is a consequence of Proposition 2.1.3 in [4].

Let $\nu : M \to X$ be the surjective morphism which sends a monad to the isomorphism class of its cohomology. The tangent space to $M$ at an arbitrary point $(A,B)$ is
\[
T_{(A,B)}M = \{ (\alpha, \beta) \mid \alpha_{12} = 0, \beta_{12} = 0, \beta \circ A + B \circ \alpha = 0 \}.
\]
Consider the map $\Phi : M \to \text{Hom}((m+11)\mathcal{O}, 4\mathcal{O}(1)), \Phi(A,B) = B_{11}$. It has surjective differential at every point. Indeed, $d\Phi_{(A,B)}(\alpha, \beta) = \beta_{11}$, so we need to show that, given $\beta_{11}$, there is $\alpha$ satisfying the equation $\beta \circ A + B \circ \alpha = 0$, that is $-\beta_{11} \circ A_{11} = B_{11} \circ \alpha_{11}$. This already follows from the surjectivity of the map $\alpha_{11} \to B_{11} \circ \alpha_{11}$, which we proved above.

We have $h^0(\mathcal{G}) = 14 - \text{rank}(H^0(B_{11}))$. The subset $N \subset M$ of monads with cohomology $\mathcal{G}$ satisfying $h^1(\mathcal{G}) \geq 2$ is the preimage under $\Phi$ of the set of morphisms of rank at most 10. Since any matrix of rank at most 10 is the limit of a sequence of matrices of rank 11, and since the derivative of $\Phi$ is surjective at every point, we deduce that $N$ is included in $\nu^{-1}(Y) \setminus \nu^{-1}(Y')$. But, according to Proposition 2.1.4, $Y$ is empty for $m \neq 0$. For $m = 0$, we shall prove at Proposition 2.2.6 below that $Y$ is closed. We conclude that $N$ is empty.

2.2. Description of the strata as quotients. In Section 2.1, we found that the moduli space $M_{\mathbb{P}^2}(5,3)$ can be decomposed into four strata:

- an open stratum $X_0$ given by the conditions
  \[
h^0(\mathcal{F}(-1)) = 0, \quad h^0(\mathcal{F} \otimes \Omega^1(1)) = 1;
  \]
 − a locally closed stratum $X_1$ of codimension 2 given by the conditions
  
  $$h^0(\mathcal{F}(-1)) = 0, \quad h^0(\mathcal{F} \otimes \Omega^1(1)) = 2;$$

 − a locally closed stratum $X_2$ of codimension 3 given by the conditions
  
  $$h^0(\mathcal{F}(-1)) = 1, \quad h^0(\mathcal{F} \otimes \Omega^1(1)) = 2;$$

 − the stratum $X_3$ of codimension 4 given by the conditions
  
  $$h^0(\mathcal{F}(-1)) = 1, \quad h^1(\mathcal{F}) = 1.$$

We shall see below at Proposition 2.2.6 that $X_3$ is closed.

In the sequel, $X_i$ will be equipped with the canonical induced reduced structure. Let $W_0, W_1, W_2, W_3$ be the sets of morphisms $\varphi$ from Propositions 2.1.2(i), 2.1.2(ii), 2.1.3, respectively Proposition 2.1.4. Each sheaf $\mathcal{F}$ giving a point in $X_i$ is the cokernel of a morphism $\varphi \in W_i$. Let $W_i = \text{Hom}(A_i, B_i)$ denote the ambient vector space containing $W_i$. Here $A_i, B_i$ are locally free sheaves on $\mathbb{P}^2$, for instance $A_0 = 2\mathcal{O}(-2) \oplus \mathcal{O}(-1), B_0 = 3\mathcal{O}$. The natural group of automorphisms $G_i = (\text{Aut}(A_i) \times \text{Aut}(B_i))/\mathbb{C}^\ast$ acts on $W_i$ by conjugation, leaving $W_i$ invariant (here $\mathbb{C}^\ast$ is embedded as the subgroup of homotheties). In this subsection, we shall prove that there exist geometric quotients $W_i/G_i$, which are smooth quasiprojective varieties ($W_3/G_3$ is even projective), such that $W_i/G_i \simeq X_i$. Whenever possible, we shall give concrete descriptions of these quotients.

**Proposition 2.2.1.** There exists a geometric quotient $W_0/G_0$, which is a smooth quasiprojective variety. Moreover, $W_0/G_0$ is isomorphic to $X_0$.

**Proof.** Let $\Lambda = (\lambda_1, \lambda_2, \mu_1)$ be a polarisation for the action of $G_0$ on $W_0$ satisfying $1/6 < \lambda_1 < 1/3$ (see [5] for the notions of polarisation and of semi-stable morphism). According to Claim 4.3 in [9], $W_0$ is the open invariant subset of injective morphisms inside the set $W_0^{\text{ss}}(\Lambda)$ of semi-stable morphisms with respect to $\Lambda$. According to Theorem 6.4 in [3], if $\lambda_1 < 1/5$, then there is a geometric quotient $W_0^{\text{ss}}(\Lambda)/G_0$, which is a projective variety (see also Corollary 7.11 in [9]). We fix $\Lambda$ satisfying $1/6 < \lambda_1 < 1/5$. It is now clear that a geometric quotient $W_0/G_0$ exists and is an open subset of $W_0^{\text{ss}}(\Lambda)/G_0$.

The morphism $W_0 \to X_0$ sending $\varphi$ to the isomorphism class of $\text{Coker}(\varphi)$ is surjective and its fibres are $G_0$-orbits, hence it factors through a bijective morphism $W_0/G_0 \to X_0$. Since $X_0$ is smooth, Zariski’s Main Theorem tells us that the latter is an isomorphism. \hfill □

We remark that $W_0$ is a proper subset of $W_0^{\text{ss}}(\Lambda)$, hence $W_0/G_0$ is a proper open subset of the projective variety $W_0^{\text{ss}}(\Lambda)/G_0$. Indeed, the morphism $\varphi_0$ represented by the matrix

$$
\begin{bmatrix}
XY & X^2 & 0 \\
XZ & 0 & X \\
0 & -XZ & Y
\end{bmatrix}
$$

is surjective and its fibres are $G_0$-orbits, hence it factors through a bijective morphism $W_0/G_0 \to X_0$. Since $X_0$ is smooth, Zariski’s Main Theorem tells us that the latter is an isomorphism. \hfill □
is not injective but is semi-stable with respect to $\Lambda$. This follows from King’s criterion of semi-stability [7], which, in our case, says that a morphism is in $W_0^\text{ss}(\Lambda)$ if and only if it is not equivalent to a morphism having one of the following forms:

$$
\begin{bmatrix}
\ast & \ast & 0 \\
\ast & \ast & 0 \\
\ast & \ast & \ast
\end{bmatrix},
\begin{bmatrix}
\ast & 0 & 0 \\
\ast & \ast & \ast \\
0 & \ast & \ast
\end{bmatrix},
\begin{bmatrix}
0 & \ast & \ast \\
0 & \ast & \ast \\
\ast & \ast & \ast
\end{bmatrix}.
$$

The first case is excluded by the fact that $\varphi_0$ has two linearly independent entries on column 3, the second case is excluded by the fact that $\varphi_0$ has two linearly independent entries on row 1. To exclude the third case, assume that

$$
\begin{bmatrix}
XY & X^2 & 0 \\
XZ & 0 & X \\
0 & -XZ & Y
\end{bmatrix}
\begin{bmatrix}
c_1 \\
c_2 \\
\ell
\end{bmatrix}
= \begin{bmatrix}
0 \\
0 \\
0
\end{bmatrix}
$$

for $c_1, c_2 \in \mathbb{C}$ and $\ell \in V^*$. Then the triple $(c_1X, c_2X, \ell)$ is a multiple of $(-X, Y, Z)$, which is absurd. The last case can also be easily excluded.

We recall from Section 2.4 in [4] the moduli spaces $N(3,m,n)$ of semi-stable Kronecker modules $f : \mathbb{C}^m \otimes V \to \mathbb{C}^n$.

**Proposition 2.2.2.** There exists a geometric quotient $W_1/G_1$ and it is a proper open subset inside a fibre bundle over $\mathbb{P}^2 \times N(3,2,3)$ with fibre $\mathbb{P}^{16}$.

**Proof.** Let $W'_1$ be the locally closed subset of $W_1$ given by the conditions that $\varphi_{12} = 0$, $\varphi_{11}$ have linearly independent entries and $\varphi_{22}$ have linearly independent maximal minors. The set of morphisms $\varphi_{11}$ form an open subset $U_1 \subset \text{Hom}(2\mathcal{O}(-2), \mathcal{O}(-1))$ and the set of morphisms $\varphi_{22}$ form an open subset $U_2 \subset \text{Hom}(2\mathcal{O}(-1), 3\mathcal{O})$. We denote $U = U_1 \times U_2$. $W'_1$ is the trivial vector bundle over $U$ with fibre $\text{Hom}(2\mathcal{O}(-2), 3\mathcal{O})$. We represent the elements of $G_1$ by pairs of matrices

$$(g, h) \in \text{Aut}(2\mathcal{O}(-2) \oplus 2\mathcal{O}(-1)) \times \text{Aut}(\mathcal{O}(-1) \oplus 3\mathcal{O}),$$

$$
g = \begin{bmatrix} g_1 & 0 \\ u & g_2 \end{bmatrix}, \quad h = \begin{bmatrix} h_1 & 0 \\ v & h_2 \end{bmatrix}.$$  

Inside $G_1$ we distinguish three subgroups: a unitary subgroup $G'_1$ given by the conditions that $g_1$, $g_2$, $h_1$, $h_2$ be the identity morphisms, a reductive subgroup $G_{1\text{red}}$ given by the conditions $u = 0$, $v = 0$ and a subgroup $S$ of $G_{1\text{red}}$ isomorphic to $\mathbb{C}^*$ given by the conditions that $g_1$, $h_1$ be the morphisms of multiplication by a non-zero constant $a$ and that $g_2$, $h_2$ be the morphisms of multiplication by a non-zero constant $b$. Note that $G_1 = G'_1G_{1\text{red}}$. Consider the $G_1$-invariant subset $\Sigma \subset W'_1$ given by the condition

$$
\varphi_{21} = \varphi_{22}u + v\varphi_{11},
\quad u \in \text{Hom}(2\mathcal{O}(-2), 2\mathcal{O}(-1)), \quad v \in \text{Hom}(\mathcal{O}(-1), 3\mathcal{O}).$$
Note that $W_1$ is the subset of injective morphisms inside $W'_1 \setminus \Sigma$, so it is open and $G_1$-invariant. Moreover, it is a proper subset as, for instance, the morphism represented by the matrix

$$
\begin{bmatrix}
  Y & X & 0 & 0 \\
  0 & Y^2 & X & 0 \\
  0 & YZ & 0 & X \\
  0 & 0 & -Z & Y \\
\end{bmatrix}
$$

is in $W'_1 \setminus \Sigma$ but is not injective. Our aim is to construct a geometric quotient of $W'_1 \setminus \Sigma$ modulo $G_1$; it will follow that $W_1/G_1$ exists and is a proper open subset of $(W'_1 \setminus \Sigma)/G_1$.

Firstly, we construct the geometric quotient $W'_1/G_1'$. Because of the conditions on $\varphi_{11}$ and $\varphi_{22}$ it is easy to check that $\Sigma$ is a subbundle of $W'_1$. The quotient bundle, denoted $Q'$, has rank 17. The quotient map $W'_1 \to Q'$ is a geometric quotient modulo $G_1'$. Moreover, the canonical action of $G_1'_{\text{red}}$ on $U$ is $Q'$-linearised and the map $W'_1 \to Q'$ is $G_1'_{\text{red}}$-equivariant. Let $\sigma$ be the zero-section of $Q'$. The restricted map $W'_1 \setminus \Sigma \to Q' \setminus \sigma$ is also a geometric quotient map modulo $G_1'$.

Let $x \in U$ be a point and let $\xi \in Q'_x$ be a non-zero vector lying over $x$. The stabiliser of $x$ in $G_1'_{\text{red}}$ is $S$ and $S\xi = \mathbb{C}^*\xi$. Thus, the canonical map $Q' \setminus \sigma \to \mathbb{P}(Q')$ is a geometric quotient modulo $S$. It remains to construct a geometric quotient of $\mathbb{P}(Q')$ modulo the induced action of $G_1'_{\text{red}}/S$.

The existence of a geometric quotient of $U$ modulo $G_1'_{\text{red}}/S$ follows from the classical geometric invariant theory. We notice that

$$G_1'_{\text{red}}/S \simeq \left( (\text{Aut}(2\mathcal{O}(-2)) \times \text{Aut}(\mathcal{O}(-1))) / \mathbb{C}^* \right) \times \left( (\text{Aut}(2\mathcal{O}(-1)) \times \text{Aut}(3\mathcal{O})) / \mathbb{C}^* \right).$$

Using King’s criterion of semi-stability [7], we can see that $U_1$ is the set of semi-stable points for the canonical action by conjugation of

$$(\text{Aut}(2\mathcal{O}(-2)) \times \text{Aut}(\mathcal{O}(-1))) / \mathbb{C}^* \quad \text{on} \quad \text{Hom}(2\mathcal{O}(-2), \mathcal{O}(-1)).$$

The resulting geometric quotient is $N(3,2,1)$ and is clearly isomorphic to $\mathbb{P}^2$. Analogously, $U_2$ is the set of semi-stable points for the action of

$$(\text{Aut}(2\mathcal{O}(-1)) \times \text{Aut}(3\mathcal{O})) / \mathbb{C}^* \quad \text{on} \quad \text{Hom}(2\mathcal{O}(-1), 3\mathcal{O})$$

and the resulting quotient is $N(3,2,3)$. According to [1], this is a smooth projective irreducible variety of dimension 6. We obtain:

$$U/(G_1'_{\text{red}}/S) \simeq N(3,2,1) \times N(3,2,3) \simeq \mathbb{P}^2 \times N(3,2,3).$$

It remains to show that $\mathbb{P}(Q')$ descends to a fibre bundle over $U/(G_1'_{\text{red}}/S)$. We consider the character $\chi$ of $G_1'_{\text{red}}$ given by $\chi(g,h) = \det(g)\det(h)^{-1}$. Note that $\chi$ is well-defined because it is trivial on homotheties. We multiply the action of $G_1'_{\text{red}}$ on $Q'$ by $\chi$ and we denote the resulting linearised bundle by $Q'_\chi$. The action of $S$ on $Q'_\chi$ is trivial, hence $Q'_\chi$ is $G_1'_{\text{red}}/S$-linearised. The
isotropy subgroup in $G_{1\text{red}}/S$ for any point in $U$ is trivial, so we can apply [6, Lemma 4.2.15], to deduce that $Q'_X$ descends to a vector bundle $Q$ over $U/(G_{1\text{red}}/S)$. The induced map $\mathbb{P}(Q') \to \mathbb{P}(Q)$ is a geometric quotient map modulo $G_{1\text{red}}/S$. We conclude that the composed map

\[ W'_1 \setminus \Sigma \to Q' \setminus \sigma \to \mathbb{P}(Q') \to \mathbb{P}(Q) \]

is a geometric quotient map modulo $G_1$ and that a geometric quotient $W_1/G_1$ exists and is a proper open subset inside $\mathbb{P}(Q)$.

□

**Proposition 2.2.3.** The geometric quotient $W_1/G_1$ is isomorphic to $X_1$.

**Proof.** As at Proposition 2.2.1, we have a canonical bijective morphism $W_1/G_1 \to X_1$. To show that this is an isomorphism we shall use the method of Theorem 3.1.6 in [4]. Our aim is to construct resolution (ii) from Proposition 2.1.2 not merely for an individual sheaf giving a point in $X_1$, but also for a flat family of sheaves giving points in $X_1$. We achieve this for local flat families by obtaining resolution (ii) in a natural manner from the relative Beilinson spectral sequence associated to the family. Thus, for any sheaf $\mathcal{F}$ giving a point in $X_1$, we need to recover its resolution from its Beilinson spectral sequence. Diagram (2.2.3) in [4] for $\mathcal{F}$ reads:

\[
\begin{array}{c}
2\mathcal{O}(-2) \xrightarrow{\varphi_1} \mathcal{O}(-1) \\
| \quad \quad \quad | \\
0 \to \mathcal{O}(-3) \xrightarrow{\varphi_4} 3\mathcal{O} \\
\end{array}
\]

Since $\mathcal{F}$ is semi-stable and maps surjectively onto $\text{Coker}(\varphi_1)$, we see that $\text{Coker}(\varphi_1)$ is the structure sheaf $\mathcal{C}_x$ of a point $x \in \mathbb{P}^2$ and that $\text{Ker}(\varphi_1)$ is isomorphic to $\mathcal{O}(-3)$. The exact sequence (2.2.5) in [4]

\[
0 \to \text{Ker}(\varphi_1) \xrightarrow{\varphi_5} \text{Coker}(\varphi_4) \to \mathcal{F} \to \text{Coker}(\varphi_1) \to 0
\]

gives the extension

\[
0 \to \text{Coker}(\varphi_5) \to \mathcal{F} \to \text{Coker}(\varphi_1) \to 0.
\]

We apply the horseshoe lemma to the above extension and to the resolutions

\[
0 \to \mathcal{O}(-3) \oplus 2\mathcal{O}(-1) \to 3\mathcal{O} \to \text{Coker}(\varphi_5) \to 0,
\]

\[
0 \to \mathcal{O}(-3) \to 2\mathcal{O}(-2) \to \mathcal{O}(-1) \to \text{Coker}(\varphi_1) \to 0.
\]

We arrive at the exact sequence

\[
0 \to \mathcal{O}(-3) \to \mathcal{O}(-3) \oplus 2\mathcal{O}(-2) \oplus 2\mathcal{O}(-1) \to \mathcal{O}(-1) \oplus 3\mathcal{O} \to \mathcal{F} \to 0.
\]

Since $H^1(\mathcal{F}) = 0$, we see that $\mathcal{O}(-3)$ can be cancelled and we get resolution (ii), as desired. □
Proposition 2.2.4. There exists a geometric quotient $W_2/G_2$, which is a proper open subset inside a fibre bundle over $N(3,3,2)$ with fibre $\mathbb{P}^{17}$. Moreover, $W_2/G_2$ is isomorphic to $X_2$.

Proof. The existence of $W_2/G_2$ follows from the construction of quotients given at Section 9.3 of [5]. Our situation is also analogous to Section 3.1.2 of [4]. We consider a polarisation $\Lambda = (\lambda_1, \mu_1, \mu_2)$ as in [5] for the action of $G_2$ on $W_2$ satisfying the condition $0 < \mu_2 < 1/3$. According to [5], Lemma 9.3.1, the open subset $W_2^{ss}(\Lambda) \subset W_2$ of semi-stable morphisms with respect to $\Lambda$ is the set of morphisms $\varphi$ for which of $\varphi_{11}$ is semi-stable with respect to the action by conjugation of $(\text{GL}(3, \mathbb{C}) \times \text{GL}(2, \mathbb{C}))/\mathbb{C}^*$ on $\text{Hom}(3\mathcal{O}(-2), 2\mathcal{O}(-1))$ and such that $\varphi$ is not equivalent to a morphism $\psi$ satisfying $\psi_{21} = 0$. According to King’s criterion of semi-stability [7], the condition on $\varphi_{11}$ is the same as saying that $\varphi_{11}$ is not equivalent to a morphism represented by a matrix having a zero-column or a zero-submatrix of size $1 \times 2$. Furthermore, this is equivalent to the condition on $\varphi_{11}$ from Proposition 2.1.3. We see now that $W_2$ is the open invariant subset of injective morphisms inside $W_2^{ss}(\Lambda)$. It is a proper subset because it is easy to construct semi-stable morphisms that are not injective, for example the morphism represented by the matrix
\[
\begin{bmatrix}
0 & X & Y \\
X & 0 & -Z \\
Y^3 & ZY^2 & 0
\end{bmatrix}.
\]

Adopting the notations of Section 3.1.2 of [4], let $N(3,3,2)$ be the moduli space of semi-stable Kronecker modules $f : 3\mathcal{O}(-2) \to 2\mathcal{O}(-1)$, let $\tau : E \otimes V \to F$ be the universal morphism on $N(3,3,2)$, let $p_1, p_2$ be the projections of $N(3,3,2) \times \mathbb{P}^2$ onto its factors and let
\[
\theta : p_1^*(E) \otimes p_2^*(\mathcal{O}(-2)) \longrightarrow p_1^*(F) \otimes p_2^*(\mathcal{O}(-1))
\]
be the morphism induced by $\tau$. The sheaf $\mathcal{U} = p_1^*(\text{Coker}(\theta^*) \otimes p_2^*\mathcal{O}(1))$ is locally free on $N(3,3,2)$ of rank 18. According to Section 9.3 of [5], $\mathbb{P}(\mathcal{U})$ is a geometric quotient of $W_2^{ss}(\Lambda)$ modulo $G_2$. Thus, $W_2/G_2$ exists and is a proper open subset of $\mathbb{P}(\mathcal{U})$.

We shall now prove that the natural bijective morphism $W_2/G_2 \to X_2$ is an isomorphism. Given $F$ in $X_2$, we need to construct a resolution as in Proposition 2.1.3 starting from the Beilinson spectral sequence of $F$. It is easier to work, instead, with the dual sheaf $\mathcal{G} = F^D(1)$, which gives a point in $\text{M}_{\mathbb{P}^2}(5,2)$. The Beilinson tableau (2.2.3) in [4] for $\mathcal{G}$ takes the form
\[
\begin{array}{c}
3\mathcal{O}(-2) \xrightarrow{\varphi_1} 3\mathcal{O}(-1) \xrightarrow{\varphi_2} \mathcal{O} \\
0 \xrightarrow{\varphi_4} 2\mathcal{O}(-1) \xrightarrow{\varphi_3} 3\mathcal{O}
\end{array}
\]
According to Section 2.2 of [4], \( \varphi_2 \) is surjective while \( \varphi_4 \) is injective. Thus, \( \text{Ker}(\varphi_2) \cong \Omega^1 \). Consider the canonical morphism

\[
\rho : 3\mathcal{O}(-2) \cong \mathcal{O}(-2) \otimes \text{Hom}(\mathcal{O}(-2), \Omega^1) \to \Omega^1.
\]

There is a morphism \( \alpha : 3\mathcal{O}(-2) \to 3\mathcal{O}(-2) \) such that \( \rho \circ \alpha = \varphi_1 \). Since \( \mathcal{G} \) maps surjectively onto \( \text{Ker}(\varphi_2)/\text{Im}(\varphi_1) \), this sheaf has rank zero, that is, \( \text{Im}(\varphi_1) \) has rank 2. This excludes the possibility \( \text{rank}(\alpha) = 1 \), because in this case \( \text{Im}(\varphi_1) \) would be isomorphic to \( \mathcal{O}(-2) \). If \( \text{rank}(\alpha) = 2 \), then \( \text{Im}(\varphi_1) \) would be isomorphic to \( 2\mathcal{O}(-2) \). In this case \( \text{Ker}(\varphi_2)/\text{Im}(\varphi_1) \) would have slope \(-1\), hence it would destabilise \( \mathcal{G} \). We deduce that \( \text{rank}(\alpha) = 3 \), hence \( \text{Im}(\varphi_1) = \text{Ker}(\varphi_2) \) and \( \text{Ker}(\varphi_1) \cong \mathcal{O}(-3) \). The exact sequence (2.2.5) in [4] takes the form

\[
0 \to \mathcal{O}(-3) \xrightarrow{\varphi_5} \text{Coker}(\varphi_4) \to \mathcal{G} \to 0.
\]

This easily yields the dual to the resolution from Proposition 2.1.3.

**Proposition 2.2.5.** There exists a geometric quotient \( W_3/G_3 \) and it is a smooth projective variety. Moreover, \( W_3/G_3 \) is isomorphic to the Hilbert flag scheme of quintic curves in \( \mathbb{P}^2 \) containing zero-dimensional subschemes of length 2.

**Proof.** Before constructing the quotient we notice that its existence already follows from [5]. Let \( \Lambda = (\lambda_1, \lambda_2, \mu_1, \mu_2) \) be a polarisation for the action of \( G_3 \) on \( \mathbb{W}_3 \), as in [5]. Using King’s criterion of semi-stability [7] we can verify that for polarisations satisfying \( \lambda_1 < \mu_1 \) and \( \lambda_1 < \mu_2 \) the set of stable points \( \mathbb{W}_3^s(\Lambda) \) coincides with the set of semi-stable points \( \mathbb{W}_3^{ss}(\Lambda) \) and is equal to \( W_3 \). According to [5], for polarisations satisfying \( \lambda_2 > 6\lambda_1 \) and \( \mu_1 > 3\mu_2 \) there is a good and projective quotient \( \mathbb{W}_3^{ss}(\Lambda)/G_3 \) containing the smooth geometric quotient \( \mathbb{W}_3^s(\Lambda)/G_3 \) as an open subset. We now choose a polarisation satisfying all the above conditions, i.e. satisfying \( 0 < \lambda_1 < 1/7 \) and \( \lambda_1 < \mu_2 < 1/4 \). We conclude that there is a smooth geometric quotient \( W_3/G_3 \), which is a projective variety.

Next we give two constructions of \( W_3/G_3 \), firstly as a bundle and secondly as a Hilbert flag scheme. The first construction uses the method of Proposition 2.2.2, which consisted of finding successively quotients modulo subgroups. Let \( W'_3 \) be the open subset of \( \mathbb{W}_3 \) given by the conditions that \( \varphi_{12} \neq 0 \) and that \( \varphi_{22} \) be non-divisible by \( \varphi_{12} \). The pairs of morphisms \( (\varphi_{12}, \varphi_{22}) \) form an open subset \( U \subset \text{Hom}(\mathcal{O}(-1), \mathcal{O} \oplus \mathcal{O}(1)) \) and \( W'_3 \) is the trivial vector bundle over \( U \) with fibre \( \text{Hom}(\mathcal{O}(-3), \mathcal{O} \oplus \mathcal{O}(1)) \). We represent the elements of \( G_3 \) by pairs of matrices

\[
(g, h) \in \text{Aut}(\mathcal{O}(-3) \oplus \mathcal{O}(-1)) \times \text{Aut}(\mathcal{O} \oplus \mathcal{O}(1)),
\]

\[
g = \begin{bmatrix} g_1 & 0 \\ u & g_2 \end{bmatrix}, \quad h = \begin{bmatrix} h_1 & 0 \\ v & h_2 \end{bmatrix}.
\]
Inside $G_3$ we distinguish two subgroups: a unitary subgroup $G'_3$ given by the conditions that $h$ be the identity morphism, $g_1 = 1$, $g_2 = 1$ and a subgroup $G''_3$ given by the condition that $g$ be the identity morphism. Consider the $G_3$-invariant subset $\Sigma \subset W'_3$ given by the conditions
\[
\varphi_{11} = \varphi_{12} u, \quad \varphi_{21} = \varphi_{22} u, \quad u \in \text{Hom}(\mathcal{O}(-3), \mathcal{O}(-1)).
\]
Note that $W_3 = W'_3 \setminus \Sigma$. Clearly $\Sigma$ is a subbundle of $W'_3$. The quotient bundle $E'$ has rank 19. The quotient map $W'_3 \to E'$ is a geometric quotient modulo $G'_3$. Moreover, the canonical action of $G'_3$ on $U$ is $E'$-linearised and the map $W'_3 \to E'$ is $G''_3$-equivariant. Let $\sigma'$ be the zero-section of $E'$. The restricted map $W_3 \to E' \setminus \sigma'$ is also a geometric quotient modulo $G'_3$.

We now construct a geometric quotient of $E'$ modulo $G''_3$. The quotient for the base $U$ can be described explicitly as follows. On $\mathbb{P}(V^*)$ we consider the trivial vector bundle with fibre $S^2 V^*$ and the subbundle with fibre $v V^*$ at any point $\langle v \rangle \in \mathbb{P}(V^*)$. Let $Q$ be the quotient bundle. Clearly, $U/G''_3$ is isomorphic to $\mathbb{P}(Q)$. Moreover, $U$ is a principal $G'_3$-bundle over $\mathbb{P}(Q)$. According to Theorem 4.2.14 in [6], $E'$ descends to a vector bundle $E$ on $\mathbb{P}(Q)$. Clearly, $E$ is the geometric quotient $E'/G''_3$. Let $\sigma$ be the zero-section of $E$. The composed map $W_3 \to E' \setminus \sigma' \to E \setminus \sigma$ is a geometric quotient modulo $G'_3 G''_3$. It is now clear that the fibre bundle $\mathbb{P}(E)$ is the geometric quotient $W_3/G_3$. Thus, $W_3/G_3$ is a fibre bundle with fibre $\mathbb{P}^{18}$ and base a fibre bundle $\mathbb{P}(Q)$ with base $\mathbb{P}^2$ and fibre $\mathbb{P}^2$.

It is clear that $\mathbb{P}(Q)$ is isomorphic to the Hilbert scheme of zero-dimensional subschemes of $\mathbb{P}^2$ of length 2. Let $F$ be the Hilbert flag scheme from the proposition viewed as a subscheme of $\mathbb{P}(Q) \times \mathbb{P}(S^5 V^*)$. Consider the map $W_3 \to F$ defined by
\[
\varphi \mapsto (\langle \varphi_{12} \rangle, \langle \varphi_{22} \mod \varphi_{12} \rangle, \langle \det(\varphi) \rangle).
\]
The fibres of this map are obviously $G_3$-orbits. To show that this map is a geometric quotient we shall construct local sections. We choose a point $x = (\langle f \rangle, \langle g \mod f \rangle, \langle h \rangle)$ in $F$. To fix notations, we write $f = X$ and we may assume that $g$ is a quadratic form in $Y$ and $Z$. There are unique forms $h_1(Y,Z)$ and $h_2(X,Y,Z)$ such that $h = h_1 + X h_2$. By hypothesis, $h_1$ is divisible by $g$. We put
\[
\sigma(x) = \begin{bmatrix} h_1/g & f \\ -h_2 & g \end{bmatrix}.
\]
Note that $\sigma$ extends to a local section in a neighbourhood of $x$ because $h_2$ and $h_1$, hence also $h_1/g$, depend algebraically on $x$. \hfill $\square$

**Proposition 2.2.6.** The geometric quotient $W_3/G_3$ is isomorphic to $X_3$. In particular, $X_3$ is a smooth closed subvariety of $\mathbb{M}_{\mathbb{P}^2}(5,3)$.

**Proof.** As above, in order to show that the bijective morphism $W_3/G_3 \to X_3$ is an isomorphism, we need to construct a resolution as in Proposition 2.1.4
starting from the Beilinson tableau (2.2.3) in [4] for $\mathcal{F}$, which takes the form:

$$
3\mathcal{O}(-2) \xrightarrow{\varphi_1} 3\mathcal{O}(-1) \xrightarrow{\varphi_2} \mathcal{O}
$$

$$
\mathcal{O}(-2) \xrightarrow{\varphi_3} 4\mathcal{O}(-1) \xrightarrow{\varphi_4} 4\mathcal{O}
$$

As at Proposition 2.2.4, $\text{Ker}(\varphi_2)$ is equal to $\text{Im}(\varphi_1)$ and $\text{Ker}(\varphi_1)$ is isomorphic to $\mathcal{O}(-3)$. The exact sequence (2.2.5) in [4] gives the resolution

$$
0 \rightarrow \mathcal{O}(-3) \xrightarrow{\varphi_5} \text{Coker}(\varphi_4) \rightarrow \mathcal{F} \rightarrow 0.
$$

We combine this sequence with the exact sequence (2.2.4) in [4] that reads as follows:

$$
0 \rightarrow \mathcal{O}(-2) \xrightarrow{\varphi_3} 4\mathcal{O}(-1) \xrightarrow{\varphi_4} 4\mathcal{O} \rightarrow \text{Coker}(\varphi_4) \rightarrow 0.
$$

Indeed, $\varphi_5$ lifts to a map $\mathcal{O}(-3) \rightarrow 4\mathcal{O}$ because $\text{Ext}^1(\mathcal{O}(-3), \text{Coker}(\varphi_3)) = 0$.

We arrive at the resolution

$$
0 \rightarrow \mathcal{O}(-2) \rightarrow \mathcal{O}(-3) \oplus 4\mathcal{O}(-1) \rightarrow 4\mathcal{O} \rightarrow \mathcal{F} \rightarrow 0.
$$

We have already seen at Proposition 2.1.4 how to derive the desired resolution of $\mathcal{F}$ from the above exact sequence.

\[\square\]

2.3. Geometric description of the strata. We recall that the stratum $X_0$ of $\mathcal{M}_{\mathbb{P}^2}(5,3)$ consists of isomorphism classes of cokernels of morphisms $\varphi = (\varphi_{11}, \varphi_{12})$ as at Proposition 2.1.2(i). We distinguish a subset $X_{01} \subset X_0$ given by the condition $\text{Coker}(\varphi_{12}) \cong \mathcal{I}_x(1) \oplus \mathcal{O}$, where $\mathcal{I}_x \subset \mathcal{O}$ is the ideal sheaf of a point $x \in \mathbb{P}^2$. Clearly $X_{01}$ is closed in $X_0$ and has codimension 1.

**Proposition 2.3.1.** The sheaves $\mathcal{F}$ giving points in $X_0 \setminus X_{01}$ are precisely the sheaves admitting a resolution of the form

$$
0 \rightarrow 2\mathcal{O}(-2) \rightarrow \Omega^1(2) \rightarrow \mathcal{F} \rightarrow 0.
$$

**Proof.** Assume that $\mathcal{F}$ gives a point in $X_0 \setminus X_{01}$. From Proposition 2.1.2(i), we have the exact sequence

$$
0 \rightarrow 2\mathcal{O}(-2) \rightarrow \text{Coker}(\varphi_{12}) \rightarrow \mathcal{F} \rightarrow 0.
$$

By hypothesis $\text{Coker}(\varphi_{12})$ is isomorphic to $\Omega^1(2)$.

Conversely, assume that $\mathcal{F}$ has a resolution as in the claim. Combining with the Euler sequence we find an injective morphism $\varphi : 2\mathcal{O}(-2) \oplus \mathcal{O}(-1) \rightarrow 3\mathcal{O}$ such that $\mathcal{F} \cong \text{Coker}(\varphi)$. The fact that $\varphi_{12}$ has linearly independent entries ensures that $\varphi$ satisfies the conditions from Proposition 2.1.2(i).

**Proposition 2.3.2.** The generic sheaves $\mathcal{F}$ from $X_{01}$ are precisely the non-split extension sheaves of the form

$$
0 \rightarrow \mathcal{I}_x(1) \rightarrow \mathcal{F} \rightarrow \mathcal{O}_Z \rightarrow 0,
$$
such that there is a global section of $\mathcal{F}$ taking the value 1 at every point of $Z$. Here $\mathcal{J}_x \subset \mathcal{O}_C$ is the ideal sheaf of a point $x$ on a quintic curve $C \subset \mathbb{P}^2$ and $Z \subset C$ is a union of four distinct points, also distinct from $x$, no three of which are colinear.

There is an open subset inside $X_{01}$ consisting of the isomorphism classes of all sheaves of the form $\mathcal{O}_C(1)(P_1 + P_2 + P_3 + P_4 - P_5)$, where $C \subset \mathbb{P}^2$ is a smooth quintic curve, $P_1, \ldots, P_5$ are distinct points on $C$ and $P_1, P_2, P_3, P_4$ are in general linear position.

Proof. We begin by noting that the sheaves giving points in $X_{01}$ are precisely the sheaves $\mathcal{F}$ admitting a resolution

$$0 \rightarrow 2\mathcal{O}(-2) \oplus \mathcal{O}(-1) \xrightarrow{\varphi} 3\mathcal{O} \rightarrow \mathcal{F} \rightarrow 0,$$

where $q_1, q_2$ are linearly independent two-forms and $\ell_1, \ell_2$ are linearly independent one-forms. For generic $\mathcal{F}$, $q_1$ and $q_2$ have no common linear factor and the conic curves they define intersect in the union $Z$ of four distinct points, no three of which are colinear and also distinct from the common zero of $\ell_1$ and $\ell_2$. We apply the snake lemma to the exact diagram:

The vertical maps are injections into the second factors, respectively projections onto the first factors. We get the exact sequence

$$0 \rightarrow \mathcal{O}(-4) \rightarrow \mathcal{I}_x(1) \rightarrow \mathcal{F} \rightarrow \mathcal{O}_Z \rightarrow 0.$$
from which the conclusion follows. For the converse, we apply the horseshoe lemma to the diagram:

By hypothesis, the morphism $\pi : \mathcal{O} \to \mathcal{O}_Z$ lifts to a morphism $\alpha : \mathcal{O} \to \mathcal{F}$. Then $\beta$, $\gamma$, $\delta$ are defined in the usual way and we claim that $\delta \neq 0$. If $\delta$ were zero, then $\gamma$ would factor through a morphism $\text{Ker}(\pi) \to \mathcal{I}_x(1)$. Since $\text{Ext}^1(\mathcal{O}_Z, \mathcal{I}_x(1)) = 0$, this morphism would lift to a map $\eta : \mathcal{O} \to \mathcal{I}_x(1)$. The composite map $2\mathcal{O}(-2) \to \mathcal{O} \xrightarrow{\alpha} \mathcal{F}$ would then coincide with the composition

$$2\mathcal{O}(-2) \to \mathcal{O} \xrightarrow{\eta} \mathcal{I}_x(1) \xrightarrow{\nu} \mathcal{J}_x(1) \xrightarrow{\xi} \mathcal{F},$$

hence $\alpha + \xi \circ \nu \circ \eta$ would factor through a morphism $\sigma : \mathcal{O}_Z \to \mathcal{F}$. We would have $\pi = \xi \circ \alpha = \xi \circ \alpha + \xi \circ \nu \circ \eta = \xi \circ \sigma \circ \pi$, hence $\xi \circ \sigma$ would be the identity morphism. The extension would split, contradicting our hypothesis on $\mathcal{F}$. Combining the resolutions for $\mathcal{J}_x(1)$ and $\mathcal{O}_Z$ and cancelling $\mathcal{O}(-4)$, we obtain the resolution

$$0 \to 2\mathcal{O}(-2) \to \mathcal{O} \oplus \mathcal{I}_x(1) \to \mathcal{F} \to 0.$$
exact cohomology sequence associated to the short exact sequence

\[ 0 \rightarrow O_C(1)(-x) \rightarrow \mathcal{F} \rightarrow O_Z \rightarrow 0. \]

We must show that each \( \varepsilon_i \) is not orthogonal to \( \text{Ker}(\delta) \). This is equivalent to saying that \( \varepsilon_i \) is not in the image of the dual map \( \delta^* \). By Serre duality, \( \delta^* \) is the restriction morphism

\[ H^0(O_C(-1)(x) \otimes \omega_C) \rightarrow H^0((O_C(-1)(x) \otimes \omega_C)|_Z) \]

\[ H^0(O_C(1)(x)) \quad H^0(O_C(1)(x)|_Z) \]

\[ H^0(O_C(1)) \quad H^0(O_C(1)|_Z) \]

The identity \( H^0(O_C(1)(x)) \simeq H^0(O_C(1)) \simeq V^* \) follows from the fact that the connecting homomorphism in the long exact cohomology sequence associated to the short exact sequence

\[ 0 \rightarrow O_C(1) \rightarrow O_C(1)(x) \rightarrow \mathbb{C}_x \rightarrow 0 \]

is non-zero. Indeed, its dual is the restriction map \( H^0(O_C(1)) \rightarrow H^0(O_C(1)|_x) \). This map is clearly non-zero. Now \( \delta^*(u) \) is a multiple of \( \varepsilon_i \) if and only if the linear form \( u \) vanishes at \( P_j \) for all \( j \neq i \). By hypothesis, the points \( P_j, j \neq i \), are non-colinear, so there is no such form \( u \) and we conclude that \( \varepsilon_i \) is not in the image of \( \delta^* \).

\[ \square \]

**Proposition 2.3.3.** The sheaves \( \mathcal{F} \) in \( X_1 \) are precisely the non-split extension sheaves of the form

\[ 0 \rightarrow \mathcal{E}^\text{D}(1) \rightarrow \mathcal{F} \rightarrow \mathbb{C}_x \rightarrow 0, \]

satisfying \( H^1(\mathcal{F}) = 0 \), where \( \mathbb{C}_x \) is the structure sheaf of a point \( x \in \mathbb{P}^2 \) and \( \mathcal{E} \) is in \( X_2 \). Here \( \mathcal{E}^\text{D} = \text{Ext}^1(\mathcal{E},\omega_{\mathbb{P}^2}) \) signifies the dual sheaf of \( \mathcal{E} \). Taking into account the duality isomorphism \([10]\), the sheaves \( \mathcal{E}^\text{D}(1) \) are precisely the sheaves \( \mathcal{G} \) in the dual stratum \( X_2^\text{D} \subset M_{\mathbb{P}^2}(5,2) \) defined by the relations

\[ h^0(\mathcal{G}(-1)) = 0, \quad h^1(\mathcal{G}) = 1, \quad h^1(\mathcal{G} \otimes \Omega^1(1)) = 3. \]

The generic sheaves in \( X_1 \) are of the form \( O_C(2)(-P_1 - P_2 - P_3 + P_4) \), where \( C \subset \mathbb{P}^2 \) is a smooth quintic curve, \( P_i \) are four distinct points on \( C \) and \( P_1, P_2, P_3 \) are non-colinear. In particular, \( X_1 \) lies in the closure of \( X_{01} \).

**Proof.** Let \( \mathcal{F} \) be in \( X_1 \). As in the proof of Proposition 2.3.2, the snake lemma gives an exact sequence

\[ 0 \rightarrow \text{Ker}(\varphi_{11}) \xrightarrow{\alpha} \text{Coker}(\varphi_{22}) \rightarrow \mathcal{F} \rightarrow \text{Coker}(\varphi_{11}) \rightarrow 0. \]
Because of the form of \( \varphi_{11} \) given at Proposition 2.1.2(ii), we have the isomorphisms \( \ker(\varphi_{11}) \cong \mathcal{O}(-3) \) and \( \coker(\varphi_{11}) \cong \mathbb{C}_x \) for a point \( x \in \mathbb{P}^2 \). Denoting \( G = \coker(\alpha) \), we have an extension
\[
0 \longrightarrow G \longrightarrow \mathcal{F} \longrightarrow \mathbb{C}_x \longrightarrow 0.
\]
Again from Proposition 2.1.2(ii), we know that \( \varphi_{22} \) is injective, hence \( G \) has a resolution of the form
\[
0 \longrightarrow \mathcal{O}(-3) \oplus 2\mathcal{O}(-1) \overset{\psi}{\longrightarrow} 3\mathcal{O} \longrightarrow G \longrightarrow 0,
\]
with \( \psi_{12} = \varphi_{22} \). According to the proof of Proposition 2.1.3, \( G \) is in the dual stratum \( X_2^D \).

Conversely, assume that \( \mathcal{F} \) is an extension as in the claim. Using the horseshoe lemma, we combine the resolutions
\[
0 \longrightarrow \mathcal{O}(-3) \longrightarrow 2\mathcal{O}(-2) \longrightarrow \mathcal{O}(-1) \longrightarrow \mathbb{C}_x \longrightarrow 0
\]
and
\[
0 \longrightarrow \mathcal{O}(-3) \oplus 2\mathcal{O}(-1) \longrightarrow 3\mathcal{O} \longrightarrow G \longrightarrow 0
\]
to obtain a resolution
\[
0 \longrightarrow \mathcal{O}(-3) \longrightarrow \mathcal{O}(-3) \oplus 2\mathcal{O}(-2) \oplus 2\mathcal{O}(-1) \longrightarrow \mathcal{O}(-1) \oplus 3\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0.
\]
Note that \( \text{Ext}^1(\mathbb{C}_x, 3\mathcal{O}) = 0 \), so we can use the arguments at Proposition 2.3.2 to show that the extension would split if the morphism \( \mathcal{O}(-3) \to \mathcal{O}(-3) \) in the above complex were zero. We deduce that this morphism is non-zero, so we may cancel \( \mathcal{O}(-3) \) to get a resolution as in Proposition 2.1.2(ii).

The part of the claim concerning generic sheaves follows from the corresponding part of Proposition 2.3.4 below.

To see that \( X_1 \) is included in \( \overline{X}_{01} \) we choose a point in \( X_1 \) represented by \( \mathcal{O}_C(2)(-P_1 - P_2 - P_3 + P_4) \). We may assume that the line through \( P_1 \) and \( P_2 \) intersects \( C \) at five distinct points \( P_1, P_2, Q_1, Q_2, Q_3 \), which are also distinct from \( P_3 \) and \( P_4 \). Then
\[
\mathcal{O}_C(2)(-P_1 - P_2 - P_3 + P_4) \cong \mathcal{O}_C(1)(Q_1 + Q_2 + Q_3 - P_3 + P_4).
\]
Clearly, we can find points \( R_1, R_2, R_3 \) on \( C \), converging to \( Q_1, Q_2, Q_3 \) respectively, which are distinct from \( P_3 \) and such that \( R_1, R_2, R_3, P_4 \) are in general linear position. Then \( \mathcal{O}_C(1)(R_1 + R_2 + R_3 + P_4 - P_3) \) represents a point in \( X_{01} \) converging to the chosen point in \( X_1 \).

We recall from the proof of Proposition 2.1.3 that the sheaves \( G \) giving points in the dual stratum \( X_2^D \subset \mathbb{M}_{\mathbb{P}^2}(5, 2) \) are precisely the sheaves that admit a resolution of the form
\[
0 \longrightarrow \mathcal{O}(-3) \oplus 2\mathcal{O}(-1) \overset{\psi}{\longrightarrow} 3\mathcal{O} \longrightarrow G \longrightarrow 0,
\]
where \( \psi_{12} \) has linearly independent maximal minors. We consider the open subset \( X^D_{20} \) of \( X^D_2 \) given by the condition that the maximal minors of \( \psi_{12} \) have no common linear factor and we denote \( X^D_{21} = X^D_2 \setminus X^D_{20} \).

**Proposition 2.3.4.**  (i) The sheaves \( \mathcal{G} \) from \( X^D_{20} \) are precisely the twisted ideal sheaves \( \mathcal{I}_Z(2) \), where \( Z \subset \mathbb{P}^2 \) is a zero-dimensional scheme of length 3 not contained in a line, contained in a quintic curve \( C \subset \mathbb{P}^2 \), and \( \mathcal{I}_Z \subset \mathcal{O}_C \) is its ideal sheaf. The generic sheaves in \( X^D_2 \) are of the form \( \mathcal{O}_C(2)(-P_1 - P_2 - P_3) \), where \( C \) is a smooth quintic curve and \( P_1, P_2, P_3 \) are non-collinear points on \( C \).

By duality, the generic sheaves in \( X_2 \) are of the form \( \mathcal{O}_C(1)(P_1 + P_2 + P_3) \). In particular, \( X_2 \) lies in the closure of \( X_1 \).

(ii) The sheaves \( \mathcal{G} \) from \( X^D_{20} \) are precisely the extension sheaves of the form

\[
0 \rightarrow \mathcal{O}_L(-1) \rightarrow \mathcal{G} \rightarrow \mathcal{O}_C(1) \rightarrow 0,
\]

where \( L \subset \mathbb{P}^2 \) is a line, \( C \subset \mathbb{P}^2 \) is a quartic curve and such that the image of \( \mathcal{G} \) under the canonical map

\[
\text{Ext}^1(\mathcal{O}_C(1), \mathcal{O}_L(-1)) \rightarrow \text{Ext}^1(\mathcal{O}(1), \mathcal{O}_L(-1))
\]

is non-zero.

**Proof.**  (i) According to Propositions 4.5 and 4.6 in [2], \( \text{Coker}(\psi_{12}) \simeq \mathcal{I}_Z(2) \), where \( Z \subset \mathbb{P}^2 \) is a zero-dimensional scheme of length 3 not contained in a line and \( \mathcal{I}_Z \subset \mathcal{O} \) is its ideal sheaf. Conversely, every \( \mathcal{I}_Z(2) \) is the cokernel of some morphism \( \psi_{12} : 2\mathcal{O}(-1) \rightarrow 3\mathcal{O} \) whose maximal minors are linearly independent and have no common linear factor. Thus, the sheaves \( \mathcal{G} \in X^D_{20} \) are precisely the cokernels of injective morphisms \( \mathcal{O}(-3) \rightarrow \mathcal{I}_Z(2) \). If \( C \) is the quintic curve defined by the inclusion \( \mathcal{O}(-3) \subset \mathcal{I}_Z(2) \subset \mathcal{O}(2) \), then it is easy to see that \( \mathcal{G} \simeq \mathcal{I}_Z(2) \).

To see that \( X_2 \) is included in \( X^D_2 \) we choose a generic sheaf in \( X_2 \) of the form \( \mathcal{O}_C(1)(P_1 + P_2 + P_3) \). We may assume that the line through \( P_1 \) and \( P_2 \) intersects \( C \) at five distinct points \( P_1, P_2, Q_1, Q_2, Q_3 \). For non-collinear points \( R_1, R_2, R_3 \) on \( C \), converging to \( Q_1, Q_2, Q_3 \) respectively, the sheaf

\[
\mathcal{O}_C(2)(-R_1 - R_2 - R_3 + P_3)
\]

\[
\simeq \mathcal{O}_C(1)(P_1 + P_2 + P_3 + Q_1 + Q_2 + Q_3 - R_1 - R_2 - R_3)
\]

represents a point in \( X_1 \) converging to the point given by \( \mathcal{O}_C(1)(P_1 + P_2 + P_3) \).

(ii) Let \( \ell \) be a common linear factor of the maximal minors of \( \psi_{12} \). Consider the line \( L \) with equation \( \ell = 0 \). According to Section 3.3.3 of [4], \( \text{Coker}(\psi_{12}) \simeq \mathcal{E}_L \), where \( \mathcal{E}_L \) is the unique non-split extension

\[
0 \rightarrow \mathcal{O}_L(-1) \rightarrow \mathcal{E}_L \rightarrow \mathcal{O}(1) \rightarrow 0.
\]

Conversely, every \( \mathcal{E}_L \) is the cokernel of some morphism \( \psi_{12} : 2\mathcal{O}(-1) \rightarrow 3\mathcal{O} \) with linearly independent maximal minors which have a common linear factor. Thus, the sheaves \( \mathcal{G} \) giving points in \( X^D_{21} \) are precisely the cokernels of the
injective morphisms $\mathcal{O}(-3) \to \mathcal{E}_L$. Let $C \subset \mathbb{P}^2$ be the quartic curve defined by the composition $\mathcal{O}(-3) \to \mathcal{E}_L \to \mathcal{O}(1)$. We apply the snake lemma to the diagram with exact rows

$$
\begin{array}{cccccc}
0 & \longrightarrow & \mathcal{O}(-3) & \longrightarrow & \mathcal{E}_L & \longrightarrow & \mathcal{G} & \longrightarrow & 0 \\
\downarrow & & \downarrow \alpha & & \downarrow & & \\
0 & \longrightarrow & \mathcal{O}(-3) & \longrightarrow & \mathcal{O}(1) & \longrightarrow & \mathcal{O}_C(1) & \longrightarrow & 0 \\
\end{array}
$$

As $\text{Ker}(\alpha) \cong \mathcal{O}_L(-1)$, we obtain an extension

$$0 \longrightarrow \mathcal{O}_L(-1) \longrightarrow \mathcal{G} \longrightarrow \mathcal{O}_C(1) \longrightarrow 0$$

which maps to the class of $\mathcal{E}_L$ in $\mathbb{P}(\text{Ext}^1(\mathcal{O}(1), \mathcal{O}_L(-1)))$. The converse is clear, in view of the fact that $\text{Ext}^1(\mathcal{O}(1), \mathcal{O}_L(-1)) \cong \mathbb{C}$. □

**Proposition 2.3.5.** The sheaves $\mathcal{F}$ giving points in $X_3$ are precisely the twisted ideal sheaves $\mathcal{J}_Z(2)$, where $Z \subset \mathbb{P}^2$ is a zero-dimensional scheme of length 2 contained in a quintic curve $C$ and $\mathcal{J}_Z \subset \mathcal{O}_C$ is its ideal sheaf.

The generic sheaves in $X_3$ are of the form $\mathcal{O}_C(1)(P_1 + P_2 + P_3)$, where $C \subset \mathbb{P}^2$ is a smooth quintic curve and $P_1, P_2, P_3$ are distinct colinear points on $C$. In particular, $X_3$ lies in the closure of $X_2$.

**Proof.** Adopting the notations of Proposition 2.1.4, we notice that the restriction of $\varphi$ to $\mathcal{O}(-1)$ has cokernel $\mathcal{I}_Z(2)$, where $Z$ is the intersection of the line with equation $\varphi_{12} = 0$ and the conic with equation $\varphi_{22} = 0$. Thus, the sheaves $\mathcal{F}$ in $X_3$ are the cokernels of injective morphisms $\mathcal{O}(-3) \to \mathcal{I}_Z(2)$. Let $C$ be the quintic curve defined by the inclusion $\mathcal{O}(-3) \subset \mathcal{I}_Z(2) \subset \mathcal{O}(2)$.

Clearly $\mathcal{F} \cong \mathcal{J}_Z(2)$.

To see that $X_3 \subset \overline{X}_2$ choose a generic sheaf $\mathcal{O}_C(1)(P_1 + P_2 + P_3)$ in $X_3$. Clearly, we can find non-colinear points $Q_1, Q_2, Q_3$ on $C$ converging to $P_1, P_2, P_3$ respectively. Then $\mathcal{O}_C(1)(Q_1 + Q_2 + Q_3)$ represents a point in $X_2$ converging to the chosen point in $X_3$. □

From what was said above, we can summarise the following proposition.

**Proposition 2.3.6.** $\{X_0 \setminus X_{01}, X_{01}, X_1, X_2, X_3\}$ represents a stratification of $\mathcal{M}_{\mathbb{P}^2}(5, 3)$ by locally closed irreducible subvarieties of codimension 0, 1, 2, 3, 4.

### 3. Euler characteristic one or four

#### 3.1. Locally free resolutions for semi-stable sheaves.

**Proposition 3.1.1.** Every sheaf $\mathcal{F}$ giving a point in $\mathcal{M}_{\mathbb{P}^2}(5, 1)$ and satisfying the condition $h^1(\mathcal{F}) = 0$ also satisfies the condition $h^0(\mathcal{F}(-1)) = 0$. These sheaves are precisely the sheaves with resolution

$$0 \longrightarrow 4\mathcal{O}(-2) \xrightarrow{\varphi} 3\mathcal{O}(-1) \oplus \mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0,$$
where $\varphi_{11}$ is not equivalent to a morphism represented by a matrix of the form
\[
\begin{bmatrix}
\begin{array}{cc}
\psi & 0 \\
* & *
\end{array}
\end{bmatrix}, \quad \text{with } \psi : m\mathcal{O}(-2) \longrightarrow m\mathcal{O}(-1), \quad m = 1, 2, 3.
\]

Proof. According to Claim 4.2 of [9], every sheaf $\mathcal{G}$ giving a point in $\mathbb{M}_{\mathbb{P}^2}(5, 4)$ and satisfying the condition $h^0(\mathcal{G}(-1)) = 0$ also satisfies the condition $h^1(\mathcal{G}) = 0$ and has a resolution
\[
0 \longrightarrow \mathcal{O}(-2) \oplus 3\mathcal{O}(-1) \overset{\varphi}{\longrightarrow} 4\mathcal{O} \longrightarrow \mathcal{G} \longrightarrow 0,
\]
where $\varphi_{12}$ is not equivalent to a morphism represented by a matrix of the form
\[
\begin{bmatrix}
* & \psi \\
* & 0
\end{bmatrix}, \quad \text{with } \psi : m\mathcal{O}(-1) \longrightarrow m\mathcal{O}, \quad m = 1, 2, 3.
\]
The result follows by duality. \qed

**Proposition 3.1.2.** Let $\mathcal{F}$ be a sheaf giving a point in $\mathbb{M}_{\mathbb{P}^2}(5, 1)$ satisfying the conditions $h^1(\mathcal{F}) = 1$ and $h^0(\mathcal{F}(-1)) = 0$. Then $h^0(\mathcal{F} \otimes \Omega^1(1)) = 0$ or 1. The sheaves in the first case are precisely the sheaves that have a resolution of the form
\[
(i) \quad 0 \longrightarrow \mathcal{O}(-3) \oplus \mathcal{O}(-2) \overset{\varphi}{\longrightarrow} 2\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0,
\]
where $\varphi_{12}$ and $\varphi_{22}$ are linearly independent two-forms. The sheaves from the second case are precisely the sheaves with resolution
\[
(ii) \quad 0 \longrightarrow \mathcal{O}(-3) \oplus \mathcal{O}(-2) \oplus \mathcal{O}(-1) \overset{\varphi}{\longrightarrow} \mathcal{O}(-1) \oplus 2\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0,
\]
where $\varphi = \begin{bmatrix} q & \ell & 0 \\ \varphi_{21} & \varphi_{22} & \ell_1 \\ \varphi_{31} & \varphi_{32} & \ell_2 \end{bmatrix}$, and $\ell$ is non-zero, $q$ is non-divisible by $\ell$ and $\ell_1, \ell_2$ are linearly independent one-forms.

Proof. Let $\mathcal{F}$ give a point in $\mathbb{M}_{\mathbb{P}^2}(5, 1)$ and satisfy the conditions $h^1(\mathcal{F}) = 1$ and $h^0(\mathcal{F}(-1)) = 0$. Put $m = h^0(\mathcal{F} \otimes \Omega^1(1))$. The Beilinson free monad (2.2.1) in [4] for $\mathcal{F}$ reads
\[
0 \longrightarrow 4\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \longrightarrow (m + 3)\mathcal{O}(-1) \oplus 2\mathcal{O} \longrightarrow \mathcal{O} \longrightarrow 0
\]
and gives the resolution
\[
0 \longrightarrow 4\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \longrightarrow \Omega^1 \oplus m\mathcal{O}(-1) \oplus 2\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0.
\]
Combining this with the standard resolution for $\Omega^1$ we obtain the following exact sequence:
\[
0 \longrightarrow \mathcal{O}(-3) \oplus 4\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \overset{\varphi}{\longrightarrow} 3\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \oplus 2\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0,
\]
with $\varphi_{13} = 0$, $\varphi_{23} = 0$. As in the proof of Proposition 2.1.4, we have $\text{rank}(\varphi_{12}) = 3$. Canceling 3 $\mathcal{O}(-2)$, we get the resolution

$$0 \rightarrow \mathcal{O}(-3) \oplus \mathcal{O}(-2) \oplus m\mathcal{O}(-1) \xrightarrow{\varphi} m\mathcal{O}(-1) \oplus 2\mathcal{O} \rightarrow \mathcal{F} \rightarrow 0,$$

with $\varphi_{13} = 0$. From the injectivity of $\varphi$, we must have $m \leq 2$. If $m = 2$, then $\text{Coker}(\varphi_{23})$ is a destabilising subsheaf of $\mathcal{F}$. We conclude that $m = 0$ or 1.

Assume that $h^0(\mathcal{F} \otimes \Omega^1(1)) = 0$. We arrive at resolution (i). If $\varphi_{12}$ and $\varphi_{22}$ were linearly dependent, then $\mathcal{F}$ would have a destabilising subsheaf of the form $\mathcal{O}_C$, for a conic curve $C \subset \mathbb{P}^2$. Conversely, we assume that $\mathcal{F}$ has resolution (i) and we must show that $\mathcal{F}$ cannot have a destabilising subsheaf $\mathcal{E}$.

We may restrict our attention to semi-stable sheaves $\mathcal{E}$. As $\mathcal{F}$ is generated by global sections, we must have $h^0(\mathcal{E}) < h^0(\mathcal{F}) = 2$. Thus, $\mathcal{E}$ is in $\mathbb{M}_{\mathbb{P}^2}(r, 1)$ for some $1 \leq r \leq 4$ and we have $h^1(\mathcal{E}) = 0$. Moreover, $H^0(\mathcal{E} \otimes \Omega^1(1))$ vanishes because the corresponding cohomology group for $\mathcal{F}$ vanishes. This excludes the possibility $r = 1$. In the case $r = 2$, $\mathcal{E}$ is the structure sheaf of a conic curve, but this, by virtue of our hypothesis on $\varphi_{12}$ and $\varphi_{22}$, is not allowed. If $\mathcal{E}$ is in $\mathbb{M}_{\mathbb{P}^2}(3, 1)$, then, according to [8], $\mathcal{E}$ has resolution

$$0 \rightarrow 2\mathcal{O}(-2) \rightarrow \mathcal{O}(-1) \oplus \mathcal{O} \rightarrow \mathcal{E} \rightarrow 0.$$

If $\mathcal{E}$ is in $\mathbb{M}_{\mathbb{P}^2}(4, 1)$, then, from the description of this moduli space found in [4], we see that $\mathcal{E}$ has resolution

$$0 \rightarrow 3\mathcal{O}(-2) \rightarrow 2\mathcal{O}(-1) \oplus \mathcal{O} \rightarrow \mathcal{E} \rightarrow 0.$$

It is easy to see that the first exact sequence must fit into a commutative diagram

$$\begin{array}{cccccc}
0 
\rightarrow 
2\mathcal{O}(-2) 
\xrightarrow{\psi} 
\mathcal{O}(-1) \oplus \mathcal{O} 
\xrightarrow{\alpha} 
\mathcal{E} 
\rightarrow 
0 \\
\downarrow \beta \\
0 
\rightarrow 
\mathcal{O}(-3) \oplus \mathcal{O}(-2) 
\xrightarrow{\varphi} 
2\mathcal{O} 
\rightarrow 
\mathcal{F} 
\rightarrow 
0
\end{array}$$

From the fact that $\alpha$ and $\alpha(1)$ are injective on global sections, we see that $\text{Coker}(\alpha)$ is supported on a line. This is impossible because $\mathcal{O}(-3)$ maps injectively to $\text{Coker}(\beta)$ which maps injectively to $\text{Coker}(\alpha)$. The same argument applies to the second exact sequence as well, except that $\text{Coker}(\alpha)$ this time would be supported on a point.

Assume now that $h^0(\mathcal{F} \otimes \Omega^1(1)) = 1$. We arrive at resolution (ii). If $\ell_1, \ell_2$ were linearly dependent, then $\mathcal{F}$ would have a destabilising subsheaf of the form $\mathcal{O}_L$, for a line $L \subset \mathbb{P}^2$. If $\ell = 0$, then $\mathcal{F}$ would have a destabilising quotient sheaf of the form $\mathcal{O}_C(-1)$, for a conic curve $C \subset \mathbb{P}^2$. If $\ell$ divided $q$, then $\mathcal{F}$ would have a destabilising quotient sheaf of the form $\mathcal{O}_L(-1)$. Conversely, we assume that $\mathcal{F}$ has resolution (ii) and we must show that there is no destabilising subsheaf. Let $x$ be the point with equations $\ell_1 = 0,$
\( \ell_2 = 0 \) and let \( Z \subset \mathbb{P}^2 \) be the zero-dimensional subscheme of length 2 given by the equations \( \ell = 0, \ q = 0 \). We apply the snake lemma to the exact diagram:

\[
\begin{array}{ccccccc}
0 & \rightarrow & \mathcal{O}(-1) & \rightarrow & \mathcal{I}_x(1) & \rightarrow & 0 \\
& & \varphi_{23} & & \varphi & & \\
0 & \rightarrow & \mathcal{O}(-3) \oplus \mathcal{O}(-2) \oplus \mathcal{O}(-1) & \rightarrow & \mathcal{O}(-1) \oplus 2\mathcal{O} & \rightarrow & \mathcal{F} & \rightarrow 0 \\
& & [q \quad \ell] & & [q \quad \ell] & & \\
\mathcal{O}(-4) & \rightarrow & \mathcal{O}(-3) \oplus \mathcal{O}(-2) & \rightarrow & \mathcal{O}(-1) & \rightarrow & \mathcal{O}_Z & \rightarrow 0 \\
& & & & & & \\
0 & \rightarrow & 0 & \rightarrow & 0 & \rightarrow & 0 \\
\end{array}
\]

We get the exact sequence

\[
0 \rightarrow \mathcal{O}(-4) \rightarrow \mathcal{I}_x(1) \rightarrow \mathcal{F} \rightarrow \mathcal{O}_Z \rightarrow 0.
\]

Let \( C \) be the quintic curve defined by the inclusion \( \mathcal{O}(-4) \subset \mathcal{I}_x(1) \subset \mathcal{O}(1) \). We obtain an exact sequence:

\[
0 \rightarrow \mathcal{J}_x(1) \rightarrow \mathcal{F} \rightarrow \mathcal{O}_Z \rightarrow 0,
\]

where \( \mathcal{J}_x \subset \mathcal{O}_C \) is the ideal sheaf of \( x \) on \( C \). Let \( \mathcal{F}' \subset \mathcal{F} \) be a non-zero subsheaf of multiplicity at most 4. Denote by \( C' \) its image in \( \mathcal{O}_Z \) and put \( \mathcal{K} = \mathcal{F}' \cap \mathcal{J}_x(1) \). By [9], Lemma 6.7, there is a sheaf \( \mathcal{A} \subset \mathcal{O}_C(1) \) containing \( \mathcal{K} \) such that \( \mathcal{A}/\mathcal{K} \) is supported on finitely many points and \( \mathcal{O}_C(1)/\mathcal{A} \simeq \mathcal{O}_S(1) \) for a curve \( S \subset \mathbb{P}^2 \) of degree \( d \leq 4 \). The slope of \( \mathcal{F}' \) can be estimated as follows:

\[
P_{\mathcal{F}'}(t) = P_{\mathcal{K}}(t) + h^0(C') = P_{\mathcal{A}}(t) - h^0(A/K) + h^0(C') = P_{\mathcal{O}_C}(t + 1) - P_{\mathcal{O}_S}(t + 1) - h^0(A/K) + h^0(C') = (5 - d)t + \frac{d^2 - 5d}{2} - h^0(A/K) + h^0(C'),
\]

\[
p(\mathcal{F}') = -\frac{d}{2} + \frac{h^0(C') - h^0(A/K)}{5 - d} \leq -\frac{d}{2} + \frac{2}{5 - d} < \frac{1}{5} = p(\mathcal{F}).
\]

We conclude that \( \mathcal{F} \) is semi-stable. \( \square \)

**Proposition 3.1.3.** There are no sheaves \( \mathcal{F} \) giving points in \( \mathcal{M}_{\mathbb{P}^2}(5,1) \) and satisfying the conditions \( h^0(\mathcal{F}(-1)) = 0 \) and \( h^1(\mathcal{F}) = 2 \).

**Proof.** By duality, we need to show that there are no sheaves \( \mathcal{G} \) in \( \mathcal{M}_{\mathbb{P}^2}(5,4) \) satisfying the conditions \( h^0(\mathcal{G}(-1)) = 2 \) and \( h^1(\mathcal{G}) = 0 \). Assume that there is
such a sheaf $\mathcal{G}$. Write $m = h^1(\mathcal{G} \otimes \Omega^1(1))$. The Beilinson monad gives a resolution
\[
0 \rightarrow 2\mathcal{O}(-2) \rightarrow 3\mathcal{O}(-2) \oplus (m + 3)\mathcal{O}(-1) \rightarrow m\mathcal{O}(-1) \oplus 4\mathcal{O} \rightarrow \mathcal{G} \rightarrow 0,
\]
\[
\eta = \begin{bmatrix} 0 \\ \psi \end{bmatrix}.
\]
Here $\varphi_{12} = 0$. As $\mathcal{G}$ maps surjectively onto $\text{Coker}(\varphi_{11})$, the latter has rank zero, forcing $m \leq 3$. In the case $m = 3$, $\text{Coker}(\varphi_{11})$ has Hilbert polynomial $P(t) = 3t$, so the semi-stability of $\mathcal{G}$ gets contradicted. Thus, $m \leq 2$.

We claim that any matrix representing a morphism equivalent to $\psi$ has three linearly independent entries on each column. The argument uses the fact that $\mathcal{G}$ has no zero-dimensional torsion and is analogous to the proof that the vector space $H$ from Proposition 2.1.4 has dimension 3. Thus, we may assume that one of the columns of $\psi$ is
\[
\begin{bmatrix} 0 \\ \cdots \\ 0 \\ X \\ Y \\ Z \end{bmatrix}^T.
\]
Let $\varphi_0$ be the matrix made of the last three columns of $\varphi_{22}$. The rows of $\varphi_0$ are linear combinations of the rows of the matrix
\[
\begin{bmatrix} -Y & X & 0 \\ -Z & 0 & X \\ 0 & -Z & Y \end{bmatrix}.
\]
It is easy to see that the elements on any row of $\varphi_0$ are linearly dependent. The rows of $\varphi_0$ cannot span a vector space of dimension 1, otherwise $\varphi_{22}$ would be equivalent to a morphism represented by a matrix having a zero-column, hence $\mathcal{O}(-1) \subset \text{Ker}(\varphi)$, which is absurd. Clearly, $\text{Ker}(\varphi_0)$ is isomorphic to $\mathcal{O}(-2)$ because $\varphi_0$ has at least two linearly independent rows. This excludes the case $m = 0$ because in that case $\varphi_0 = \varphi_{22}$ and $\text{Ker}(\varphi_{22}) \simeq 2\mathcal{O}(-2)$. In the remaining two cases we shall prove that the rows of $\varphi_0$ cannot span a vector space of dimension 2. We argue by contradiction. Assume that $m = 2$ and that $\varphi_0$ is equivalent to a matrix of the form
\[
\begin{bmatrix} 0 \\ \xi \end{bmatrix},
\]
where $\xi$ is a $2 \times 3$-matrix with linearly independent rows. Then $\text{Ker}(\xi) \simeq \mathcal{O}(-2)$ and $\text{Coker}(\xi) \simeq \mathcal{O}_L(1)$ for a line $L \subset \mathbb{P}^2$. The first isomorphism is obvious and tells us that the maximal minors of $\xi$ are linearly independent and have a common linear factor, say $\ell$. Let $L \subset \mathbb{P}^2$ be the line with equation $\ell = 0$. Note that $\text{Coker}(\xi)$ is supported on $L$ and has Hilbert polynomial $P(t) = t + 2$. Moreover, it is easy to see that $\xi$ has rank 1 at every point of $L$, hence $\text{Coker}(\xi)$ has no zero-dimensional torsion. This proves the second isomorphism. We now use the argument from the proof of Proposition 2.1.4.
There is a commutative diagram

\[
\begin{array}{ccccccccc}
3\mathcal{O}(-1) & \xrightarrow{\xi} & 2\mathcal{O} & \rightarrow & \mathcal{O}_L(1) & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \\
3\mathcal{O}(-2) \oplus 5\mathcal{O}(-1) & \xrightarrow{\varphi} & 2\mathcal{O}(-1) \oplus 4\mathcal{O} & \rightarrow & \mathcal{G} & \rightarrow & 0
\end{array}
\]

in which the first two vertical maps are injective. The induced morphism \(\mathcal{O}_L(1) \rightarrow \mathcal{G}\) is zero because both sheaves are stable and \(p(\mathcal{O}_L(1)) > p(\mathcal{G})\). Thus the map \(4\mathcal{O} \rightarrow \mathcal{G}\) is not injective on global sections. On the other hand, \(H^0(Coker(\eta))\) vanishes, hence the map \(4\mathcal{O} \rightarrow \mathcal{G}\) is injective on global sections. We have arrived at a contradiction. We conclude that the rows of \(\varphi_0\) span a vector space of dimension 3.

Modulo elementary operations on rows and columns, \(\psi\) is equivalent to a morphism represented by a matrix having one of the following forms:

\[
\begin{bmatrix}
0 & 0 \\
0 & 0 \\
X & R \\
Y & S \\
Z & T
\end{bmatrix}
\quad \text{or} \quad
\begin{bmatrix}
0 & 0 \\
X & 0 \\
Y & R \\
Z & S \\
0 & T
\end{bmatrix}
\quad \text{or} \quad
\begin{bmatrix}
X & 0 \\
0 & Y \\
0 & 0 \\
Z & R \\
0 & T
\end{bmatrix}
\]

Here \(R, S, T\) form a basis of \(V^*\). In the first case, the triple \((R, S, T)\) is a multiple of \((X, Y, Z)\), because, as we saw above, \(\ker(\varphi_0) \simeq \mathcal{O}(-2)\). Thus, \(\psi\) is represented by a matrix with a zero-column. This is absurd. In the second case, we can perform elementary row operations on the matrix

\[
\begin{bmatrix}
X & 0 \\
0 & X \\
-Z & Y
\end{bmatrix}
\]

to get the matrix

\[
\begin{bmatrix}
-S & R \\
-T & 0 \\
0 & -T
\end{bmatrix}
\] .

It follows that

\[
\text{span}\{X\} = \text{span}\{X, Z\} \cap \text{span}\{X, Y\} = \text{span}\{S, T\} \cap \text{span}\{R, T\} = \text{span}\{T\}
\]

and \((-S, R) = a(-Z, Y) + (bX, cX)\) for some \(a, b, c \in \mathbb{C}\). Thus, \(\psi\) is equivalent to the morphism represented by the matrix

\[
\begin{bmatrix}
0 & X & Y & Z & 0 \\
0 & 0 & 0 & 0 & X
\end{bmatrix}^T.
\]
This, as we saw above, is not possible. In the third case, we can perform elementary row operations on the matrix
\[
\begin{bmatrix}
0 \\ X \\ Y
\end{bmatrix}
\]
to get the matrix
\[
\begin{bmatrix}
S \\ T \\ 0
\end{bmatrix}.
\]
Thus, we may assume that $S = X$, $T = Y$, $R = Z$. Performing elementary row and column operations on $\psi$ we can get a matrix with three zeros on a column. This, as we saw above, is not possible. Thus far, we have eliminated the case when $m = 2$. The case when $m = 1$ can be eliminated in an analogous fashion. We conclude that there are no sheaves $G$ as above.

**Proposition 3.1.4.** There are no sheaves $F$ giving points in $\mathbb{M}_{\mathbb{P}^2}(5,1)$ and satisfying the conditions $h^0(F(-1)) = 0$ and $h^1(F) \geq 2$.

**Proof.** The argument is the same as at Proposition 2.1.6 or at Theorem 3.2.3 in [4]. Using the Beilinson monad for $F(-1)$ we see that the open subset of $\mathbb{M}_{\mathbb{P}^2}(5,1)$ given by the condition $h^0(F(-1)) = 0$ is parametrised by an open subset $M$ inside the space of monads of the form
\[
0 \longrightarrow 9\mathcal{O}(-1) \xrightarrow{A} 13\mathcal{O} \xrightarrow{B} 4\mathcal{O}(1) \longrightarrow 0.
\]
The map $\Phi : M \rightarrow \text{Hom}(13\mathcal{O}, 4\mathcal{O}(1))$ is defined by $\Phi(A,B) = B$. Using the vanishing of $H^1(F(1))$ for an arbitrary sheaf in $\mathbb{M}_{\mathbb{P}^2}(5,1)$, we prove that $\Phi$ has surjective differential at every point of $M$. This further leads to the conclusion that the set of monads in $M$ whose cohomology sheaf $F$ satisfies $h^1(F) \geq 2$ is included in the closure of the set of monads for which $h^1(F) = 2$. According to Proposition 3.1.3, the latter set is empty, hence the former set is empty, too.

**Proposition 3.1.5.** The sheaves $F$ giving points in $\mathbb{M}_{\mathbb{P}^2}(5,1)$ and satisfying the condition $h^0(F(-1)) > 0$ are precisely the sheaves with resolution of the form
\[
0 \longrightarrow 2\mathcal{O}(-3) \xrightarrow{\varphi} \mathcal{O}(-2) \oplus \mathcal{O}(1) \longrightarrow F \longrightarrow 0,
\]
where $\ell_1, \ell_2$ are linearly independent one-forms. For these sheaves, we have $h^0(F(-1)) = 1$ and $h^1(F) = 2$. These sheaves are precisely the non-split extension sheaves of the form
\[
0 \longrightarrow \mathcal{O}_C(1) \longrightarrow F \longrightarrow \mathbb{C}_x \longrightarrow 0,
\]
where $C \subset \mathbb{P}^2$ is a quintic curve and $\mathbb{C}_x$ is the structure sheaf of a point.
Proof. Assume that \( F \) gives a point in \( M_{\mathbb{P}^2}(5,1) \) and satisfies the condition \( h^0(F(-1)) > 0 \). As in the proof of Proposition 2.1.3 in [4], there is an injective morphism \( \mathcal{O}_C \rightarrow F(-1) \) for some quintic curve \( C \subset \mathbb{P}^2 \). We obtain a non-split extension

\[
0 \rightarrow \mathcal{O}_C(1) \rightarrow F \rightarrow \mathbb{C}_x \rightarrow 0.
\]

Conversely, using the fact that \( \mathcal{O}_C \) is stable, it is easy to see that any non-split extension sheaf as above gives a point in \( M_{\mathbb{P}^2}(5,1) \).

Assume now that \( F \) has a resolution as in the claim. Let \( x \) be the point given by the ideal \((\ell_1, \ell_2)\) and let \( \mathcal{I}_x \subset \mathcal{O} \) be its ideal sheaf. Let \( f = \ell_1 f_2 - \ell_2 f_1 \) and let \( C \) be the quintic curve with equation \( f = 0 \). We apply the snake lemma to the commutative diagram with exact rows

\[
\begin{array}{cccccccc}
0 & \rightarrow & \mathcal{O}(-4) & \rightarrow & 2\mathcal{O}(-3) & \rightarrow & \mathcal{I}_x(-2) & \rightarrow & 0 \\
\downarrow f & & \downarrow \varphi & & \downarrow i & & \downarrow p & & \downarrow & \\
0 & \rightarrow & \mathcal{O}(1) & \rightarrow & \mathcal{O}(-2) \oplus \mathcal{O}(1) & \rightarrow & \mathcal{O}(-2) & \rightarrow & 0 \\
\end{array}
\]

Here \( i \) is the inclusion into the second factor and \( p \) is the projection onto the first factor. We deduce that \( F \) is an extension of \( \mathbb{C}_x \) by \( \mathcal{O}_C(1) \). As \( h^0(F) = 3 \), the extension does not split.

Conversely, assume that \( F \) is a non-split extension of \( \mathbb{C}_x \) by \( \mathcal{O}_C(1) \). We construct a resolution of \( F \) from the standard resolution of \( \mathcal{O}_C(1) \) and from the resolution

\[
0 \rightarrow \mathcal{O}(-4) \rightarrow 2\mathcal{O}(-3) \rightarrow \mathcal{O}(-2) \rightarrow \mathcal{C}_x \rightarrow 0,
\]

using the horseshoe lemma. We obtain a resolution of the form

\[
0 \rightarrow \mathcal{O}(-4) \rightarrow \mathcal{O}(-4) \oplus 2\mathcal{O}(-3) \xrightarrow{\varphi} \mathcal{O}(-2) \oplus \mathcal{O}(1) \rightarrow F \rightarrow 0.
\]

If the map \( \mathcal{O}(-4) \rightarrow \mathcal{O}(-4) \) in the above resolution were zero, then, as in the proof of Proposition 2.3.2, the extension would split. This would be contrary to our hypothesis. We conclude that \( \mathcal{O}(-4) \) can be cancelled in the above exact sequence and we arrive at the resolution from the proposition. \( \square \)

3.2. Description of the strata as quotients. In Section 3.1, we found that the moduli space \( M_{\mathbb{P}^2}(5,1) \) can be decomposed into four strata:

- an open stratum \( X_0 \) given by the condition \( h^1(F) = 0 \);
- a locally closed stratum \( X_1 \) of codimension 2 given by the conditions
  \[
  h^0(F(-1)) = 0, \quad h^1(F) = 1, \quad h^0(F \otimes \Omega^1(1)) = 0;
  \]
- a locally closed stratum \( X_2 \) of codimension 3 given by the conditions
  \[
  h^0(F(-1)) = 0, \quad h^1(F) = 1, \quad h^0(F \otimes \Omega^1(1)) = 1;
  \]
– the stratum $X_3$ of codimension 5 given by the conditions

$$h^0 (\mathcal{F}(-1)) = 1, \quad h^1 (\mathcal{F}) = 2.$$

We shall see below at Proposition 3.2.5 that $X_3$ is closed.

In the sequel, $X_i$ will be equipped with the canonical reduced structure induced from $M_{\mathbb{P}^2}(5,1)$. Let $W_0$, $W_1$, $W_2$, $W_3$ be the sets of morphisms $\varphi$ from Propositions 3.1.1, 3.1.2(i), 3.1.2(ii), respectively, Proposition 3.1.5. Each sheaf $\mathcal{F}$ giving a point in $X_i$ is the cokernel of a morphism $\varphi \in W_i$. Let $\mathbb{W}_i$ be the ambient vector spaces of morphisms of sheaves containing $W_i$, for example, $\mathbb{W}_0 = \text{Hom}(4\mathcal{O}(-2), 3\mathcal{O}(-1) \oplus \mathcal{O})$. Let $G_i$ be the natural groups of automorphisms acting by conjugation on $\mathbb{W}_i$. In this subsection, we shall prove that there exist geometric quotients $W_i / G_i$, which are smooth quasiprojective varieties, such that $W_i / G_i \simeq X_i$. We shall also give concrete descriptions of these quotients.

**Proposition 3.2.1.** There exists a geometric quotient $W_0 / G_0$, which is a proper open subset inside a fibre bundle over $\text{N}(3,4,3)$ with fibre $\mathbb{P}^{14}$. Moreover, $W_0 / G_0$ is isomorphic to $X_0$.

**Proof.** The situation is analogous to Proposition 2.2.4. Let $\Lambda = (\lambda_1, \mu_1, \mu_2)$ be a polarisation for the action of $G_0$ on $\mathbb{W}_0$ satisfying $0 < \mu_2 < 1/4$. Note that $W_0$ is the proper open invariant subset of injective morphisms inside $\mathbb{W}_0^\text{ss}(\Lambda)$. As usual, we denote by $\text{N}(3,4,3)$ the moduli space of semi-stable Kronecker modules $f : 4\mathcal{O}(-2) \rightarrow 3\mathcal{O}(-1)$ and let

$$\theta : p_1^* (E) \otimes p_2^* (\mathcal{O}(-2)) \longrightarrow p_1^* (F) \otimes p_2^* (\mathcal{O}(-1))$$

be the morphism of sheaves on $\text{N}(3,4,3) \times \mathbb{P}^2$ induced from the universal morphism $\tau$. Then $U = p_1^* (\text{Coker}(\theta^*))$ is a vector bundle of rank 15 on $\text{N}(3,4,3)$ and $\mathbb{P}(U)$ is the geometric quotient $\mathbb{W}_0^\text{ss}(\Lambda) / G_0$. Thus, $W_0 / G_0$ exists and is a proper open subset of $\mathbb{P}(U)$.

The canonical morphism $W_0 / G_0 \rightarrow X_0$ is bijective and, since $X_0$ is smooth, it is an isomorphism.

**Proposition 3.2.2.** There exists a geometric quotient $W_1 / G_1$ and it is a proper open subset inside a fibre bundle with fibre $\mathbb{P}^{16}$ and base the Grassmann variety Grass$(2, S^2 V^*)$. Moreover, $W_1 / G_1$ is isomorphic to $X_1$.

**Proof.** The existence of $W_1 / G_1$ follows from Section 9.3 of [5]. Consider a polarisation $\Lambda = (\lambda_1, \lambda_2, \mu_1)$ for the action of $G_1$ on $\mathbb{W}_1$ satisfying the condition $0 < \lambda_1 < 1/2$. Then $\mathbb{W}_1^\text{ss}(\Lambda)$ is given by the conditions that $\varphi_{12}, \varphi_{22}$ be linearly independent two-forms and that the first column of $\varphi$ be not a multiple of the second column. Thus, $W_1$ is the proper open invariant subset of injective morphisms inside $\mathbb{W}_1^\text{ss}(\Lambda)$. The semi-stable morphisms that are not injective are represented by matrices of the form

$$\begin{bmatrix} q\ell_1 & \ell\ell_1 \\ q\ell_2 & \ell\ell_2 \end{bmatrix}$$
with $\ell \in V^*$ non-zero, $q \in S^2V^*$ non-divisible by $\ell$ and $\ell_1, \ell_2 \in V^*$ linearly independent. The moduli space $N(6,1,2)$ of semi-stable Kronecker modules $f : \mathcal{O}(-2) \to 2\mathcal{O}$ is isomorphic to $\text{Grass}(2,S^2V^*)$. Let

$$\theta : p^*_1(E) \otimes p^*_2(\mathcal{O}(-2)) \longrightarrow p^*_1(F)$$

be the morphism of sheaves on $N(6,1,2) \times \mathbb{P}^2$ induced from the universal morphism $\tau$. Then $U = p^*_1(\text{Coker}(\theta) \otimes p^*_2(\mathcal{O}(3)))$ is a vector bundle of rank 17 over $N(6,1,2)$ and $\mathbb{P}(U)$ is the geometric quotient $\mathbb{W}^{ss}_1(\Lambda)/G_1$. Thus $W_1/G_1$ exists and is a proper open subset of the projective variety $\mathbb{P}(U)$.

To show that the canonical bijective morphism $W_1/G_1 \to X_1$ is an isomorphism, we shall construct resolution (i) from Proposition 3.1.2 for a sheaf $F$ giving a point in $X_1$ in a natural manner from the Beilinson diagram (2.2.3) in [4] for $F$, which has the form

$$4\mathcal{O}(-2) \xrightarrow{\varphi_1} 3\mathcal{O}(-1) \xrightarrow{\varphi_2} \mathcal{O}$$

According to Section 2.2 of [4], $\varphi_2$ is surjective, so $\text{Ker}(\varphi_2) \simeq \Omega^1$. Recall the morphism $\rho$ introduced in the proof of Proposition 2.2.4. There is a morphism $\alpha : 4\mathcal{O}(-2) \to 3\mathcal{O}(-2)$ such that $\rho \circ \alpha = \varphi_1$. As at Proposition 2.2.4, we have $\text{rank}(\alpha) = 3$, forcing

$$\text{Ker}(\varphi_2) = \text{Im}(\varphi_1) \quad \text{and} \quad \text{Ker}(\varphi_1) \simeq \mathcal{O}(-3) \oplus \mathcal{O}(-2).$$

The exact sequence (2.2.5) in [4] takes the form

$$0 \longrightarrow \text{Ker}(\varphi_1) \xrightarrow{\varphi_2} 2\mathcal{O} \longrightarrow F \longrightarrow 0$$

and gives us resolution (i) from Proposition 3.1.2. In this fashion, we construct a local inverse to the morphism $W_1/G_1 \to X_1$. We conclude that this is an isomorphism.

**Proposition 3.2.3.** There exists a geometric quotient $W_2/G_2$ and it is a proper open subset inside a fibre bundle with fibre $\mathbb{P}^{17}$ and base $Y \times \mathbb{P}^2$, where $Y$ is the Hilbert scheme of zero-dimensional subschemes of $\mathbb{P}^2$ of length 2.

**Proof.** To obtain $W_2/G_2$ we shall construct successively quotients modulo subgroups of $G_2$, as at Propositions 2.2.2 and 2.2.5. Let $W'_2 \subset W_2$ be the locally closed subset of morphisms $\varphi$ satisfying the conditions from Proposition 3.1.2(ii), except injectivity. The pairs of morphisms $(\varphi_{11}, \varphi_{12})$ form an open subset $U_1 \subset \text{Hom}(\mathcal{O}(-3) \oplus \mathcal{O}(-2), \mathcal{O}(-1))$ and the morphisms $\varphi_{23}$ form an open subset $U_2$ inside $\text{Hom}(\mathcal{O}(-1), 2\mathcal{O})$. We denote $U = U_1 \times U_2$. Clearly,
$W'_2$ is the trivial vector bundle on $U$ with fibre $\text{Hom}(\mathcal{O}(-3) \oplus \mathcal{O}(-2), 2\mathcal{O})$. We represent the elements of $G_2$ by pairs of matrices

$$(g, h) \in \text{Aut}(\mathcal{O}(-3) \oplus \mathcal{O}(-2) \oplus \mathcal{O}(-1)) \times \text{Aut}(\mathcal{O}(-1) \oplus 2\mathcal{O}),$$

$$g = \begin{bmatrix} g_{11} & 0 & 0 \\ u_{21} & g_{22} & 0 \\ u_{31} & u_{32} & g_{33} \end{bmatrix}, \quad h = \begin{bmatrix} h_{11} & 0 & 0 \\ v_{21} & h_{22} & h_{23} \\ v_{31} & h_{32} & h_{33} \end{bmatrix}. $$

Inside $G_2$ we distinguish four subgroups: a reductive subgroup $G_{2\text{red}}$ given by the conditions $u_{ij} = 0$, $v_{ij} = 0$, the subgroup $S$ of pairs $(g, h)$ of the form

$$g = \begin{bmatrix} a & 0 & 0 \\ 0 & a & 0 \\ 0 & 0 & b \end{bmatrix}, \quad h = \begin{bmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & b \end{bmatrix},$$

with $a, b \in \mathbb{C}^*$, and two unitary subgroups $G'_2$ and $G''_2$. Here $G'_2$ consists of pairs $(g, h)$ of morphisms of the form

$$g = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ u_{31} & u_{32} & 1 \end{bmatrix}, \quad h = \begin{bmatrix} 1 & 0 & 0 \\ v_{21} & 1 & 0 \\ v_{31} & 0 & 1 \end{bmatrix},$$

while $G''_2$ is given by pairs $(g, h)$, where

$$g = \begin{bmatrix} 1 & 0 & 0 \\ u_{21} & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad h = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}. $$

Note that $G_2 = G'_2 G''_2 G_{2\text{red}}$. Consider the $G_2$-invariant subset $\Sigma$ of $W'_2$ of morphisms of the form

$$\begin{bmatrix} q \\ v_{21}q + \ell_1 u_{31} \\ v_{31}q + \ell_2 u_{31} \end{bmatrix} v_{21} \ell + \ell_1 u_{32} \ell_1 + \ell_2 u_{32} \ell_2 \begin{bmatrix} \ell \\ 0 \\ 0 \end{bmatrix}. $$

Note that $W_2$ is the subset of injective morphisms inside $W'_2 \setminus \Sigma$, so it is open and $G_2$-invariant. Moreover, it is a proper subset as, for instance, the morphism represented by the matrix

$$\begin{bmatrix} X^2 - Y^2 & X & 0 \\ XZ^2 & Z^2 & Y \\ YZ^2 & 0 & X \end{bmatrix}$$

is in $W'_2 \setminus \Sigma$ but is not injective. Our aim is to construct a geometric quotient of $W'_2 \setminus \Sigma$ modulo $G_2'$; it will follow that $W_2/G_2$ exists and is a proper open subset of $(W'_2 \setminus \Sigma)/G_2$.

Firstly, we construct the geometric quotient $W'_2/G'_2$. Because of the conditions on $q, \ell, \ell_1, \ell_2$, it is easy to see that $\Sigma$ is a subbundle of $W'_2$ of rank 14. The quotient bundle, denoted $E'$, has rank 18. The quotient map $W'_2 \to E'$ is a geometric quotient modulo $G'_2$. Moreover, the canonical action of $G''_2 G_{2\text{red}}$
on $U$ is $E'$-linearised and the map $W_2' \to E'$ is $G_2''\text{red}$-equivariant. Let $\sigma'$ be the zero-section of $E'$. The restricted map $W_2' \setminus \Sigma \to E' \setminus \sigma'$ is also a geometric quotient modulo $G_2''$.

Secondly, we construct a geometric quotient of $E'$ modulo $G_2''$. The quotient for the base $U$ can be described explicitly as follows. On $V^*$ we consider the trivial bundle with fibre $S^2V^*$ and the subbundle with fibre $vV^*$ at any point $v \in V^*$. The quotient bundle $Q'$ is the geometric quotient $U_1/G_2''$ and $U/G_2'' \simeq (U_1/G_2'') \times U_2$. Clearly, $U$ is a principal $G_2''$-bundle over $U/G_2''$. According to Theorem 4.2.14 in [6], $E'$ descends to a vector bundle $E$ over $U/G_2''$. The canonical map $E' \to E$ is a geometric quotient modulo $G_2''$. The composed map $W_2' \to E' \to E$ is a geometric quotient modulo $G_2''$. Moreover, the canonical action of $G_2\text{red}$ on $U/G_2''$ is linearised with respect to $E$ and the map $W_2' \to E$ is $G_2\text{red}$-equivariant. Let $\sigma$ be the zero-section of $E$. The restricted map $W_2' \setminus \Sigma \to E' \setminus \sigma' \to E \setminus \sigma$ is also a geometric quotient modulo $G_2''$.

Let $x \in U/G_2''$ be a point and let $\xi \in E_x$ be a non-zero vector lying over $x$. The stabiliser of $x$ in $G_2\text{red}$ is $S$ and $S\xi = C^*\xi$. Thus, the canonical map $E \setminus \sigma \to \mathbb{P}(E)$ is a geometric quotient modulo $S$. It remains to construct a geometric quotient of $\mathbb{P}(E)$ modulo the induced action of $G_2\text{red}/S$. Clearly, $(U/G_2’’)/(G_2\text{red}/S)$ exists and is isomorphic to $\mathbb{P}(Q) \times \mathbb{P}^2$, where $Q$ is the bundle on $\mathbb{P}(V^*)$ to which $Q'$ descends. As noted in the proof of Proposition 2.2.5, $\mathbb{P}(Q)$ is the Hilbert scheme of zero-dimensional subschemes of $\mathbb{P}^2$ of length 2. It remains to show that $\mathbb{P}(E)$ descends to a fibre bundle on $\mathbb{P}(Q) \times \mathbb{P}^2$. We consider the character $\chi$ of $G_2\text{red}$ given by $\chi(g,h) = \det(g)\det(h)^{-1}$. Note that $\chi$ is well-defined because it is trivial on homotheties. We multiply the action of $G_2\text{red}$ on $E$ by $\chi$ and we denote the resulting linearised bundle by $E_\chi$. The action of $S$ on $E_\chi$ is trivial, hence $E_\chi$ is $G_2\text{red}/S$-linearised. The isotropy subgroup in $G_2\text{red}/S$ for any point in $U/G_2''$ is trivial, so we can apply [6], Lemma 4.2.15, to deduce that $E_\chi$ descends to a vector bundle $F$ over $\mathbb{P}(Q) \times \mathbb{P}^2$. The induced map $\mathbb{P}(E) \to \mathbb{P}(F)$ is a geometric quotient map modulo $G_2\text{red}/S$. We conclude that the composed map

$$W_2' \setminus \Sigma \to E' \setminus \sigma' \to E \setminus \sigma \to \mathbb{P}(E) \to \mathbb{P}(F)$$

is a geometric quotient map modulo $G_2$ and that a geometric quotient $W_2/G_2$ exists and is a proper open subset inside $\mathbb{P}(F)$.

\[\square\]

**Proposition 3.2.4.** The geometric quotient $W_2/G_2$ is isomorphic to $X_2$.

**Proof.** We must construct resolution (ii) from Proposition 3.1.2 starting from the Beilinson spectral sequence for $\mathcal{F}$. We prefer to work, instead, with the sheaf $\mathcal{G} = \mathcal{F}_D(1)$, which gives a point in $\mathbb{M}_{PD}(5,4)$. Diagram (2.2.3) in [4]
for $\mathcal{G}$ takes the form

\[ 2\mathcal{O}(-2) \xrightarrow{\varphi_1} \mathcal{O}(-1) \xrightarrow{\varphi_2} \mathcal{O}(-2) \xrightarrow{\varphi_3} 4\mathcal{O}(-1) \xrightarrow{\varphi_4} 4\mathcal{O}. \]

Since $\mathcal{G}$ maps surjectively onto $\text{Coker}(\varphi_1)$ and is semi-stable, $\varphi_1$ cannot be zero and $\text{Coker}(\varphi_1)$ cannot be isomorphic to $\mathcal{O}_L(-1)$ for a line $L \subset \mathbb{P}^2$. Thus $\text{Coker}(\varphi_1)$ is the structure sheaf of a point $x \in \mathbb{P}^2$ and $\ker(\varphi_1) \simeq \mathcal{O}(-3)$. The exact sequence (2.2.5) in [4] reads:

\[ 0 \rightarrow \mathcal{O}(-3) \xrightarrow{\varphi_2} \text{Coker}(\varphi_4) \rightarrow \mathcal{G} \rightarrow \mathbb{C}_x \rightarrow 0. \]

We see from this that $\text{Coker}(\varphi_4)$ has no zero-dimensional torsion. The exact sequence (2.2.4) in [4] takes the form

\[ 0 \rightarrow \mathcal{O}(-2) \xrightarrow{\varphi_3} 4\mathcal{O}(-1) \xrightarrow{\varphi_4} 4\mathcal{O} \rightarrow \text{Coker}(\varphi_4) \rightarrow 0. \]

We claim that $\varphi_3$ is equivalent to the morphism represented by the matrix

\[ \begin{bmatrix} X & Y & Z & 0 \end{bmatrix}^T. \]

The argument uses the fact that $\text{Coker}(\varphi_4)$ has no zero-dimensional torsion and is analogous to the proof that the vector space $H$ from Proposition 2.1.4 has dimension 3. Now we can describe $\varphi_4$. We claim that $\varphi_4$ is equivalent to a morphism represented by a matrix of the form

\[ \begin{bmatrix} -Y & X & 0 & \star \\ -Z & 0 & X & \star \\ 0 & -Z & Y & \star \\ 0 & 0 & 0 & \ell \end{bmatrix} \]

with $\ell \in V^*$. The argument, we recall from the proof of Proposition 3.1.3, uses the fact that the map $4\mathcal{O} \rightarrow \text{Coker}(\varphi_4)$ is injective on global sections and the fact that the only morphism $\mathcal{O}_L(1) \rightarrow \text{Coker}(\varphi_4)$ for any line $L \subset \mathbb{P}^2$ is the zero-morphism. Indeed, such a morphism must factor through $\varphi_5$ because the composed map $\mathcal{O}_L(1) \rightarrow \text{Coker}(\varphi_4) \rightarrow \mathcal{G}$ is zero. This follows from the fact that both $\mathcal{O}_L(1)$ and $\mathcal{G}$ are semi-stable and $p(\mathcal{O}_L(1)) > p(\mathcal{G})$.

If $\ell = 0$, then $\text{Coker}(\varphi_4)$ would have a direct summand with Hilbert polynomial $P(t) = 2t + 3$. Such a sheaf must map injectively to $\mathcal{G}$, because its intersection with $\mathcal{O}(-3)$ could only be the zero-sheaf. This contradicts the semi-stability of $\mathcal{G}$. Thus, $\ell \neq 0$. Let $L$ be the line with equation $\ell = 0$. We obtain the extension

\[ 0 \rightarrow \mathcal{O}(1) \rightarrow \text{Coker}(\varphi_4) \rightarrow \mathcal{O}_L \rightarrow 0, \]

which yields the resolution

\[ 0 \rightarrow \mathcal{O}(-1) \rightarrow \mathcal{O} \oplus \mathcal{O}(1) \rightarrow \text{Coker}(\varphi_4) \rightarrow 0. \]
Write \( C = \text{Coker}(\varphi_5) \). Since \( \text{Ext}^1(\mathcal{O}(-3), \mathcal{O}(-1)) = 0 \), the morphism \( \varphi_5 \) lifts to a morphism \( \mathcal{O}(-3) \rightarrow \mathcal{O} \oplus \mathcal{O}(1) \). We obtain the resolution
\[
0 \longrightarrow \mathcal{O}(-3) \oplus \mathcal{O}(-1) \longrightarrow \mathcal{O} \oplus \mathcal{O}(1) \longrightarrow C \longrightarrow 0.
\]
We now apply the horseshoe lemma to the extension \( \mathcal{G} \) of \( \mathbb{C}_x \) by \( C \), to the above resolution of \( C \) and to the standard resolution of \( \mathbb{C}_x \) tensored with \( \mathcal{O}(-1) \). We obtain the resolution
\[
0 \longrightarrow \mathcal{O}(-3) \longrightarrow \mathcal{O}(-3) \oplus 2\mathcal{O}(-2) \oplus \mathcal{O}(-1) \longrightarrow \mathcal{O}(-1) \oplus \mathcal{O} \oplus \mathcal{O}(1) \longrightarrow \mathcal{G} \longrightarrow 0.
\]
The morphism \( \mathcal{O}(-3) \rightarrow \mathcal{O}(-3) \) is non-zero because \( H^1(\mathcal{G}) \) vanishes. We may cancel \( \mathcal{O}(-3) \) we get the dual of resolution (ii) from Proposition 3.1.2.

**Proposition 3.2.5.** There exists a geometric quotient \( W_3/G_3 \), which is isomorphic to the universal quintic inside \( \mathbb{P}^2 \times \mathbb{P}(S^5V^*) \). Moreover, \( W_3/G_3 \) is isomorphic to \( X_3 \), so this is a smooth closed subvariety of \( M_{\mathbb{P}^2}(5,1) \).

**Proof.** For the first part of the claim, we refer to Section 3.2 in [4]. Succinctly, the map of \( W_3 \) to the universal quintic given by
\[
\begin{bmatrix}
\ell_1 & \ell_2 \\
\ell_1 & f_2
\end{bmatrix} \longrightarrow (x, \langle \ell_1 f_2 - \ell_2 f_1 \rangle), \quad \text{where } x \text{ is the zero-set of } \ell_1 \text{ and } \ell_2,
\]
is a geometric quotient map. Clearly, the natural morphism \( W_3/G_3 \rightarrow X_3 \) is bijective. In order to show that it is an isomorphism, we need to derive a resolution as in Proposition 3.1.5 starting from the Beilinson spectral sequence of \( \mathcal{F} \) and performing algebraic operations (compare Theorem 3.1.6 in [4]). By duality, we may also start with the Beilinson spectral sequence for the sheaf \( \mathcal{G} = \mathcal{F}^0(1) \). Table (2.2.3) in [4] for \( E^1(\mathcal{G}) \) takes the form
\[
3\mathcal{O}(-2) \xrightarrow{\varphi_1} 3\mathcal{O}(-1) \xrightarrow{\varphi_2} \mathcal{O}
\]
\[
2\mathcal{O}(-2) \xrightarrow{\varphi_3} 6\mathcal{O}(-1) \xrightarrow{\varphi_4} 5\mathcal{O}
\]
As in the proof of Proposition 2.2.4, we have \( \text{Ker}(\varphi_3) = \text{Im}(\varphi_1) \) and \( \text{Ker}(\varphi_1) \simeq \mathcal{O}(-3) \). The exact sequence (2.2.5) in [4]
\[
0 \longrightarrow \mathcal{O}(-3) \xrightarrow{\varphi_3} \text{Coker}(\varphi_4) \longrightarrow \mathcal{G} \longrightarrow 0
\]
yields the resolution
\[
0 \longrightarrow 2\mathcal{O}(-2) \xrightarrow{\eta} \mathcal{O}(-3) \oplus 6\mathcal{O}(-1) \longrightarrow 5\mathcal{O} \longrightarrow \mathcal{G} \longrightarrow 0,
\]
\[
\eta = \begin{bmatrix}
0 \\
\varphi_3
\end{bmatrix}.
\]
As in the proof of Proposition 3.1.3, we can show that any matrix equivalent to the matrix representing \( \varphi_3 \) has three linearly independent entries on each
column. It follows that, modulo elementary operations on rows and columns, \( \varphi_3 \) is represented by a matrix having one of the following forms:

\[
\begin{bmatrix}
0 & 0 \\
0 & 0 \\
0 & X \\
X & R \\
Y & S \\
Z & T
\end{bmatrix}
\] or

\[
\begin{bmatrix}
0 & 0 \\
0 & 0 \\
0 & Y \\
X & 0 \\
Y & R \\
Z & S
\end{bmatrix}
\] or

\[
\begin{bmatrix}
0 & 0 \\
0 & 0 \\
0 & Z \\
X & 0 \\
Y & 0 \\
Z & T
\end{bmatrix}
\] or

\[
\begin{bmatrix}
X & 0 \\
0 & Y \\
0 & 0 \\
0 & 0 \\
Z & 0 \\
S & T
\end{bmatrix}
\] or

\[
\begin{bmatrix}
X & 0 \\
0 & Y \\
0 & 0 \\
0 & 0 \\
Z & 0 \\
0 & X
\end{bmatrix}
\] .

Here \( R, S, T \) form a basis of \( V^* \). As in the proof of Proposition 3.1.3, it can be shown that the first three matrices are unfeasible. We are left with the last possibility.

By virtue of [10], Lemma 3, taking duals of the locally free sheaves occurring in the above resolution of \( G \) yields a monad with middle cohomology \( \mathcal{F} \) of the form

\[
0 \longrightarrow 5\mathcal{O}(-2) \longrightarrow 6\mathcal{O}(-1) \oplus \mathcal{O}(1) \xrightarrow{\eta^T} 2\mathcal{O} \longrightarrow 0.
\]

From this, we get the resolution

\[
0 \longrightarrow 5\mathcal{O}(-2) \longrightarrow 2\Omega^1 \oplus \mathcal{O}(1) \longrightarrow \mathcal{F} \longrightarrow 0.
\]

Combining with the standard resolution of \( \Omega^1 \) yields the exact sequence

\[
0 \longrightarrow 2\mathcal{O}(-3) \oplus 5\mathcal{O}(-2) \xrightarrow{\varphi} 6\mathcal{O}(-2) \oplus \mathcal{O}(1) \longrightarrow \mathcal{F} \longrightarrow 0.
\]

From the semi-stability of \( \mathcal{F} \), we see that \( \text{rank}(\varphi_{12}) = 5 \), so we may cancel \( 5\mathcal{O}(-2) \) to get the desired resolution for \( \mathcal{F} \). \qed

**3.3. Geometric description of the strata.** Let \( \mathcal{F} = \text{Coker}(\varphi) \) be a sheaf in \( X_0 \) with \( \varphi \) as in Proposition 3.1.1. We recall that \( \varphi_{11} \) is semi-stable as a Kronecker \( V \)-module. We shall decompose \( X_0 \) into locally closed subsets according to the kernel of \( \varphi_{11} \). We have an exact sequence

\[
0 \longrightarrow \mathcal{O}(-d) \xrightarrow{\eta} 4\mathcal{O}(-2) \xrightarrow{\varphi_{11}} 3\mathcal{O}(-1) \longrightarrow \text{Coker}(\varphi_{11}) \longrightarrow 0,
\]

\[
\eta = [\eta_1 \ \eta_2 \ \eta_3 \ \eta_4]^T, \quad \eta_i = (-1)^i \varphi_i / g,
\]

where \( \varphi_i \) is the maximal minor of \( \varphi_{11} \) obtained by deleting the \( i \)th column and \( g = \gcd(\varphi_1, \varphi_2, \varphi_3, \varphi_4) \). The maximal minors of a generic morphism \( \varphi_{11} \) have no common factor, that is, \( \text{Ker}(\varphi_{11}) \simeq \mathcal{O}(-5) \). We denote by \( X_{01} \) and \( X_{02} \) the subsets of \( X_0 \) for which \( \text{Ker}(\varphi_{11}) \) is isomorphic to \( \mathcal{O}(-4) \), respectively to \( \mathcal{O}(-3) \). The case \( \text{deg}(g) = 3 \) is not feasible, because in this case \( \varphi_{11} \) is equivalent to a morphism represented by a matrix with a zero-column, contrary to semi-stability. As before, the superscript \( ^D \) applied to a subset of \( \mathbb{P}^2(5, 1) \) will signify the corresponding subset of \( \mathbb{P}^2(5, 4) \) obtained by duality.

**Proposition 3.3.1.** The sheaves \( \mathcal{G} \) from \( (X_0 \setminus (X_{01} \cup X_{02}))^D \subset \mathbb{P}^2(5, 4) \) have the form \( \mathcal{J}_Z(3) \), where \( Z \subset \mathbb{P}^2 \) is a zero-dimensional scheme of length 6.
not contained in a conic curve, contained in a quintic curve \( C \), and \( \mathcal{J}_Z \subset \mathcal{O}_C \) is its ideal sheaf.

The generic sheaves \( \mathcal{G} \) in \( X^0_0 \) have the form \( \mathcal{O}_C(3)(-P_1 - \cdots - P_6) \), where \( C \subset \mathbb{P}^2 \) is a smooth quintic curve and \( P_i, 1 \leq i \leq 6 \), are distinct points on \( C \) not contained in a conic curve. By duality, the generic sheaves \( \mathcal{F} \) in \( X_0 \) have the form \( \mathcal{O}_C(P_1 + \cdots + P_6) \).

Proof. The sheaves \( \mathcal{G} \) from \( (X_0 \setminus (X_{01} \cup X_{02}))^0 \) are precisely the sheaves with resolution

\[
0 \rightarrow \mathcal{O}(-2) \oplus 3\mathcal{O}(-1) \xrightarrow{\psi} 4\mathcal{O} \rightarrow \mathcal{G} \rightarrow 0,
\]

where \( \psi_{12} \) is semi-stable as a Kronecker \( V \)-module and its maximal minors have no common factor. According to Propositions 4.5 and 4.6 in [2], \( \text{Coker}(\psi_{12}) \simeq \mathcal{I}_Z(3) \), where \( Z \subset \mathbb{P}^2 \) is a zero-dimensional scheme of length 6 not contained in a conic curve. Conversely, any \( \mathcal{I}_Z(3) \) is the cokernel of some \( \psi_{12} \) with the above properties. The conclusion now follows as at Proposition 2.3.4(i).

\[\blacktriangleright\]

**Proposition 3.3.2.** The sheaves \( \mathcal{F} \) giving points in \( X_{02} \) are precisely the extension sheaves

\[
0 \rightarrow \mathcal{O}_{C'}, \rightarrow \mathcal{F} \rightarrow \mathcal{O}_C \rightarrow 0,
\]
satisfying \( H^1(\mathcal{F}) = 0 \). Here \( C' \) and \( C \) are arbitrary cubic, respectively conic curves in \( \mathbb{P}^2 \).

Proof. Assume that \( \mathcal{F} \) is in \( X_{02} \), that is, \( \text{Ker}(\varphi_{11}) \simeq \mathcal{O}(-3) \). The entries of \( \eta \) span \( V^* \), otherwise the semi-stability of \( \varphi_{11} \), as a Kronecker \( V \)-module, would get contradicted. For instance, if

\[
\eta \sim \begin{bmatrix} X \\ Y \\ 0 \\ 0 \end{bmatrix},
\]

then

\[
\varphi_{11} \sim \begin{bmatrix} -Y & X & * & * \\ 0 & 0 & * & * \\ 0 & 0 & * & * \end{bmatrix}.
\]

Thus

\[
\eta \sim \begin{bmatrix} X \\ Y \\ Z \\ 0 \end{bmatrix},
\]

forcing

\[
\varphi_{11} \sim \begin{bmatrix} -Y & X & 0 & * \\ -Z & 0 & X & * \\ 0 & -Z & Y & * \end{bmatrix} = \begin{bmatrix} \rho & * \\ * & * \end{bmatrix}.
\]
We have an exact sequence
\[ 0 \to \mathcal{O}(-2) \to \text{Coker}(\rho) \to \text{Coker}(\varphi_{11}) \to 0 \]
hence, since \( \text{Coker}(\rho) \cong \mathcal{O} \), we have an isomorphism \( \text{Coker}(\varphi_{11}) \cong \mathcal{O}_C \) for a conic curve \( C \subset \mathbb{P}^2 \). Applying the snake lemma to the exact diagram

\[
\begin{array}{ccccccccc}
0 & \to & \mathcal{O}(-2) & \to & 3\mathcal{O}(-1) & \oplus & \mathcal{O} & \to & \mathcal{F} & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \to & \mathcal{O}(-3) & \to & 4\mathcal{O}(-2) & \to & 3\mathcal{O}(-1) & \to & \mathcal{O}_C & \to & 0 \\
\end{array}
\]

we get an extension as in the proposition. Conversely, assume we are given an extension
\[ 0 \to \mathcal{O}_C' \to \mathcal{F} \to \mathcal{O}_C \to 0 \]
satisfying \( H^1(\mathcal{F}) = 0 \). We shall first show that there is a resolution for \( \mathcal{O}_C \) as in the diagram above. Combining the exact sequences
\[ 0 \to \mathcal{O}(-3) \to 3\mathcal{O}(-2) \xrightarrow{\rho} 3\mathcal{O}(-1) \to \mathcal{O} \to 0 \]
and
\[ 0 \to \mathcal{O}(-2) \to \mathcal{O} \to \mathcal{O}_C \to 0 \]
we obtain the resolution
\[ 0 \to \mathcal{O}(-3) \xrightarrow{\eta} 4\mathcal{O}(-2) \xrightarrow{\psi} 3\mathcal{O}(-1) \to \mathcal{O}_C \to 0. \]
We need to prove that \( \psi \) is semi-stable as a Kronecker \( V \)-module. Since \( \eta \) has three linearly independent entries, \( \psi \) must have three linearly independent maximal minors, and this rules out the cases when \( \psi \) could be equivalent to a matrix having a zero-column or a zero-submatrix of size \( 2 \times 2 \). It remains to rule out the case
\[
\psi = \begin{bmatrix}
-Y & X & 0 & R \\
-Z & 0 & X & S \\
0 & 0 & 0 & T
\end{bmatrix}.
\]
Denote
\[
\xi = \begin{bmatrix}
-Y & X & 0 \\
-Z & 0 & X
\end{bmatrix}.
\]
and let $L_1$, $L_2$ be the lines with equations $X = 0$, respectively $T = 0$. The snake lemma applied to the exact diagram

\[
\begin{array}{ccccccccc}
0 & \rightarrow & \mathcal{O}(-3) & \rightarrow & 3\mathcal{O}(-2) & \rightarrow & 2\mathcal{O}(-1) & \rightarrow & \mathcal{O}_{L_1} & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & \mathcal{O}(-3) & \rightarrow & 4\mathcal{O}(-2) & \rightarrow & 3\mathcal{O}(-1) & \rightarrow & \mathcal{O}_C & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & \mathcal{O}(-2) & \rightarrow & \mathcal{O}(-1) & \rightarrow & \mathcal{O}_{L_2}(-1) & \rightarrow & 0 & & \\
\end{array}
\]

yields an extension

\[
0 \rightarrow \mathcal{O}_{L_1} \rightarrow \mathcal{O}_C \rightarrow \mathcal{O}_{L_2}(-1) \rightarrow 0.
\]

This gives $h^0(\mathcal{O}_C \otimes \Omega^1(1)) = 1$, which is absurd, namely $H^0(\mathcal{O}_C \otimes \Omega^1(1))$ vanishes. Thus $\psi$ is semi-stable. We now apply the horseshoe lemma to the extension

\[
0 \rightarrow \mathcal{O}_{C'} \rightarrow \mathcal{F} \rightarrow \mathcal{O}_C \rightarrow 0,
\]

to the standard resolution of $\mathcal{O}_{C'}$ and to the resolution of $\mathcal{O}_C$ from above. We obtain the exact sequence

\[
0 \rightarrow \mathcal{O}(-3) \rightarrow \mathcal{O}(-3) \oplus 4\mathcal{O}(-2) \rightarrow 3\mathcal{O}(-1) \oplus \mathcal{O} \rightarrow \mathcal{F} \rightarrow 0.
\]

By hypothesis $H^1(\mathcal{F})$ vanishes, hence the map $\mathcal{O}(-3) \rightarrow \mathcal{O}(-3)$ is non-zero. Cancelling $\mathcal{O}(-3)$ we obtain a resolution as in Proposition 3.1.1 in which $\varphi_{11} = \psi$ is a semi-stable Kronecker $V$-module. We conclude that $\mathcal{F}$ gives a point in $X_{02}$. □

Let $X_{10} \subset X_1$ be the open subset given by the condition that $\varphi_{12}$ and $\varphi_{22}$ have no common linear term. We denote by $X_{11} = X_1 \setminus X_{10}$ the complement.

**Proposition 3.3.3.** (i) The sheaves $\mathcal{F}$ giving points in $X_{10}$ are precisely the sheaves $J_Z(2)$, where $Z \subset \mathbb{P}^2$ is the intersection of two conic curves without common component, $Z$ is contained in a quintic curve $C \subset \mathbb{P}^2$ and $J_Z \subset \mathcal{O}_C$ is its ideal sheaf.

The generic sheaves in $X_1$ are of the form $\mathcal{O}_C(2)(-P_1 - P_2 - P_3 - P_4)$, where $C \subset \mathbb{P}^2$ is a smooth quintic curve and $P_i$, $1 \leq i \leq 4$, are distinct points on $C$ in general linear position.
(ii) The sheaves $\mathcal{F}$ giving points in $X_{11}$ are precisely the extension sheaves

$$0 \to \mathcal{O}_L(-1) \to \mathcal{F} \to \mathcal{J}_x(1) \to 0$$

satisfying $\mathcal{H}^0(\mathcal{F} \otimes \Omega^1(1)) = 0$. Here $L \subset \mathbb{P}^2$ is a line and $\mathcal{J}_x \subset \mathcal{O}_C$ is the ideal sheaf of a point $x$ on a quartic curve $C \subset \mathbb{P}^2$.

Proof. (i) Adopting the notations of 3.1.2(i), we notice that the restriction of $\varphi$ to $\mathcal{O}(-2)$ has cokernel $\mathcal{I}_Z(2)$, where $Z$ is the subscheme of length 4 in $\mathbb{P}^2$ given by the equations $\varphi_{12} = 0$, $\varphi_{22} = 0$. The sheaves in $X_{10}$ are precisely the cokernels of injective morphisms $\mathcal{O}(-3) \to \mathcal{I}_Z(2)$. Let $C$ be the quintic curve defined by the inclusion $\mathcal{O}(-3) \subset \mathcal{I}_Z(2) \subset \mathcal{O}(2)$. We have $\mathcal{F} \simeq \mathcal{J}_Z(2)$.

(ii) Let us write $\varphi_{12} = \ell \psi_{12}$, $\varphi_{22} = \ell \psi_{22}$, with $\ell, \psi_{12}, \psi_{22}$ non-zero one-forms, $\psi_{12}$ and $\psi_{22}$ linearly independent. Consider the morphism

$$\psi : \mathcal{O}(-3) \oplus \mathcal{O}(-1) \to 2\mathcal{O}, \quad \psi = \begin{bmatrix} \varphi_{11} & \psi_{12} \\ \varphi_{21} & \psi_{22} \end{bmatrix}.$$ 

Clearly, Coker$(\psi)$ is isomorphic to a sheaf of the form $\mathcal{J}_x(1)$ as in the claim. Conversely, any sheaf $\mathcal{J}_x(1)$ is the cokernel of some injective morphism $\psi$ with linearly independent entries $\psi_{12}$ and $\psi_{22}$. Let $L$ be the line with equation $\ell = 0$. We apply the snake lemma to the diagram with exact rows

$$0 \to \mathcal{O}(-3) \oplus \mathcal{O}(-2) \to \mathcal{O}(-1) \oplus \mathcal{O} \to \mathcal{F} \to 0$$

As $\text{Coker}(\alpha) \simeq \mathcal{O}_L(-1)$, we get the extension

$$0 \to \mathcal{O}_L(-1) \to \mathcal{F} \to \mathcal{J}_x(1) \to 0.$$ 

Conversely, assume that $\mathcal{F}$ is an extension of $\mathcal{J}_x(1)$ by $\mathcal{O}_L(-1)$ satisfying the condition $\mathcal{H}^0(\mathcal{F} \otimes \Omega^1(1)) = 0$. Combining the resolutions for these two sheaves we get the exact sequence

$$0 \to \mathcal{O}(-3) \oplus \mathcal{O}(-2) \oplus \mathcal{O}(-1) \to \mathcal{O}(-1) \oplus 2\mathcal{O} \to \mathcal{F} \to 0.$$ 

Our cohomological condition in the hypothesis ensures that $\mathcal{O}(-1)$ may be cancelled, hence we obtain a resolution as in Proposition 3.1.2(i) with $\varphi_{12} = \ell \psi_{12}$ and $\varphi_{22} = \ell \psi_{22}$. Thus, $\mathcal{F}$ gives a point in $X_{11}$. \qed

**Proposition 3.3.4.** The generic sheaves from $X_2$ are precisely the non-split extension sheaves

$$0 \to \mathcal{J}_x(1) \to \mathcal{F} \to \mathcal{O}_Z \to 0$$
for which there is a global section of $\mathcal{F}(1)$ taking the value 1 at every point of $Z$. Here $\mathcal{J}_x \subset \mathcal{O}_C$ is the ideal sheaf of a point $x$ on a quintic curve $C \subset \mathbb{P}^2$ and $Z \subset C$ is the union of two distinct points, also distinct from $x$.

There is an open subset of $X_2$ consisting of the isomorphism classes of all sheaves of the form $\mathcal{O}_C(1)(-P_1 + P_2 + P_3)$, where $C \subset \mathbb{P}^2$ is a smooth quintic curve and $P_1, P_2, P_3$ are distinct points on $C$. In particular, $X_2$ lies in the closure of $X_1$ and $X_3$ lies in the closure of $X_2$.

**Proof.** One direction was proven at Proposition 3.1.2(ii). Given $\mathcal{F}$ in $X_2$, there is an extension as in the claim with $x$ given by the equations $\ell_1 = 0, \ell_2 = 0, Z$ given by the equations $q = 0, \ell = 0$ and $C$ given by the equation $\det(\varphi) = 0$.

For the converse, we apply the horseshoe lemma to the resolutions

$$0 \rightarrow \mathcal{O}(-4) \rightarrow \mathcal{I}_x(1) \rightarrow \mathcal{J}_x(1) \rightarrow 0$$

and

$$0 \rightarrow \mathcal{O}(-4) \xrightarrow{\zeta} \mathcal{O}(-3) \oplus \mathcal{O}(-2) \xrightarrow{\xi} \mathcal{O}(-1) \xrightarrow{\pi} \mathcal{O}_Z \rightarrow 0,$$

where $\zeta = \begin{bmatrix} -\ell \\ q \end{bmatrix}$ and $\xi = \begin{bmatrix} q & \ell \end{bmatrix}$.

By hypothesis, $\pi$ lifts to a morphism $\alpha : \mathcal{O}(-1) \rightarrow \mathcal{F}$. We define morphisms $\beta, \gamma, \delta$ as at Proposition 2.3.2. By the reason given there, $\delta$ is non-zero, namely, if $\delta$ were zero, then the extension for $\mathcal{F}$ would split. We arrive at the resolution

$$0 \rightarrow \mathcal{O}(-3) \oplus \mathcal{O}(-2) \rightarrow \mathcal{O}(-1) \oplus \mathcal{I}_x(1) \rightarrow \mathcal{F} \rightarrow 0,$$

which, further, yields resolution (ii) from Proposition 3.1.2.

Assume now that $C$ is smooth and write $x = P_1, Z = \{P_2, P_3\}$. The only non-trivial extension sheaf of $\mathcal{O}_Z$ by $\mathcal{J}_x(1)$ is isomorphic to the sheaf $\mathcal{F} = \mathcal{O}_C(1)(-P_1 + P_2 + P_3)$. We must show that $\mathcal{F}(1)$ has a global section that does not vanish at $P_2$ and $P_3$. We argue as at Proposition 2.3.2. Let $\varepsilon_2, \varepsilon_3 : H^0(\mathcal{O}_Z) \rightarrow \mathbb{C}$ be the linear forms of evaluation at $P_2, P_3$. Let $\delta : H^0(\mathcal{O}_Z) \rightarrow H^1(\mathcal{J}_x(2))$ be the connecting homomorphism in the long exact cohomology sequence associated to the short exact sequence

$$0 \rightarrow \mathcal{O}_C(2)(-x) \rightarrow \mathcal{F}(1) \rightarrow \mathcal{O}_Z \rightarrow 0.$$ 

We must show that neither $\varepsilon_2$ nor $\varepsilon_3$ is orthogonal to $\text{Ker}(\delta)$. This is equivalent to saying that neither $\varepsilon_2$ nor $\varepsilon_3$ are in the image of the dual map $\delta^*$. By
Serre duality, $\delta^*$ is the restriction morphism

$$
\begin{array}{c}
H^0(\mathcal{O}_C(-2)(x) \otimes \omega_C) \\
\downarrow \\
H^0(\mathcal{O}_C(x)) \\
\downarrow \\
H^0(\mathcal{O}_C) \cong \mathbb{C} \\
\downarrow \\
\mathbb{C}^2 \cong H^0(\mathcal{O}_C|_Z)
\end{array}
$$

The linear forms $\varepsilon_2$ and $\varepsilon_3$ correspond to the vectors $(1,0)$ and $(0,1)$ in $\mathbb{C}^2$, so they are clearly not in the image of $\delta^*$. The identity $H^0(\mathcal{O}_C(x)) = H^0(\mathcal{O}_C)$ follows from the fact that there is no rational function on $C$ that has exactly one pole of multiplicity 1. If this were the case, $C$ would have genus 0.

To see that $X_2 \subset X_1$ choose a point in $X_2$ given by $\mathcal{O}_C(1)(-P_1 + P_2 + P_3)$. We may assume that $P_1, P_2, P_3$ are non-colinear and that the line through $P_2$ and $P_3$ intersects $C$ at five distinct points denoted $P_2, P_3, Q_1, Q_2, Q_3$. Then $\mathcal{O}_C(1)(-P_1 + P_2 + P_3)$ is isomorphic to $\mathcal{O}_C(2)(-P_1 - Q_1 - Q_2 - Q_3)$. Clearly, we can find points $R_1, R_2, R_3$ on $C$, converging to $Q_1, Q_2, Q_3$ respectively, such that $P_1, R_1, R_2, R_3$ are in general linear position. Thus, the semi-stable sheaf $\mathcal{O}_C(2)(-P_1 - R_1 - R_2 - R_3)$ gives a point in $X_1$ converging to the chosen point in $X_2$.

According to Proposition 3.1.5, the generic sheaves in $X_3$ have the form $\mathcal{O}_C(1)(P)$, where $C \subset \mathbb{P}^2$ is a smooth quintic curve and $P$ is a point on $C$. Choose distinct points $P_1, P_2$ on $C$, which are also distinct from $P$, such that $P_2$ converges to $P_1$. The stable-equivalence class of $\mathcal{O}_C(1)(-P_1 + P_2 + P)$ is in $\mathcal{X}_2$ and converges to the stable-equivalence class of $\mathcal{O}_C(1)(P)$. We conclude that $X_3 \subset \mathcal{X}_2$.

The following result will be helpful in the discussion about sheaves from $X_{01}$, which we have left for the end.

**Proposition 3.3.5.** Let $\psi : 4\mathcal{O}(-2) \to 3\mathcal{O}(-1)$ be a Kronecker $V$-module. Let $\psi_i$, $1 \leq i \leq 4$, denote the maximal minor of $\psi$ obtained by deleting the $i^{th}$ column. Assume that the minors $\psi_i$ have a common linear factor. Then $Ker(\psi) \cong \mathcal{O}(-4)$ and $\psi$ is semi-stable if and only if $\psi_i$, $1 \leq i \leq 4$, are linearly independent three-forms.

**Proof.** Assume that $Ker(\psi) \cong \mathcal{O}(-4)$ and that $\psi$ is semi-stable. We argue by contradiction. If the maximal minors of $\psi$ were linearly dependent, then, performing possibly column operations on $\psi$, we could assume that one of them is zero, say $\psi_4 = 0$. Let $\psi'$ be the matrix obtained from $\psi$ by deleting the fourth column. It is easy to see that $\psi'$ is semi-stable as a Kronecker $V$-module. It follows that $\psi'$ is equivalent to the morphism represented by
the matrix
\[
\begin{bmatrix}
-Y & X & 0 \\
-Z & 0 & X \\
0 & -Z & Y
\end{bmatrix}.
\]

Thus, the vector
\[
\begin{bmatrix}
X \\
Y \\
Z \\
0
\end{bmatrix}
\]

is in the kernel of \( \psi \). This contradicts our hypothesis that \( \text{Ker}(\psi) \) be isomorphic to \( \mathcal{O}(-4) \).

Conversely, assume that \( \psi_i, 1 \leq i \leq 4 \), are linearly independent. Then they cannot have a common factor of degree 2, that is, in view of the comments at the beginning of this subsection, we have \( \text{Ker}(\psi) \simeq \mathcal{O}(-4) \). The semi-stability of \( \psi \) is also clear: if \( \psi \) were equivalent to a matrix having a zero-column, then the \( \psi_i \) would span a vector space of dimension at most 1. If \( \psi \) were equivalent to a matrix having a zero-submatrix of size \( 2 \times 2 \), then the \( \psi_i \) would span a vector space of dimension at most two. If \( \psi \) were equivalent to a matrix having a zero-submatrix of size \( 1 \times 3 \), then the \( \psi_i \) would span a vector space of dimension at most 3. □

**Proposition 3.3.6.** The sheaves \( \mathcal{F} \) giving points in \( X_{01} \) occur as non-split extension sheaves of one of the following three kinds:

(i) \( 0 \rightarrow \mathcal{G} \rightarrow \mathcal{F} \rightarrow \mathcal{O}_L \rightarrow 0 \),

where \( H^1(\mathcal{F}) = 0 \). Here \( L \subset \mathbb{P}^2 \) is a line and \( \mathcal{G} \) is in the exceptional divisor of \( M_{\mathbb{P}^2}(4,0) \). For fixed \( L \) and \( \mathcal{G} \) the feasible extension sheaves form a locally closed subset of \( \mathbb{P}(\text{Ext}^1(\mathcal{O}_L, \mathcal{G})) \).

(ii) \( 0 \rightarrow \mathcal{E} \rightarrow \mathcal{F} \rightarrow \mathcal{O}_Z \rightarrow 0 \).

Here \( Z \subset \mathbb{P}^2 \) is a zero-dimensional scheme of length 3 not contained in a line and \( \mathcal{E} \) is a sheaf in \( M_{\mathbb{P}^2}(5,-2) \) such that \( \mathcal{E}(1) \) belongs to the stratum \( X_3 \) of \( M_{\mathbb{P}^2}(5,3) \).

(iii) \( 0 \rightarrow \mathcal{O}_L(-1) \rightarrow \mathcal{F} \rightarrow \mathcal{J}_Z(1)^D \rightarrow 0 \).

Here \( L \subset \mathbb{P}^2 \) is a line and \( Z \subset \mathbb{P}^2 \) is a zero-dimensional scheme of length 3 not contained in a line, contained in a quartic curve \( C \subset \mathbb{P}^2 \), and \( \mathcal{J}_Z \subset \mathcal{O}_C \) is its ideal sheaf. For fixed \( \mathcal{J}_Z \) and \( L \) the feasible extension sheaves form a locally closed subset of \( \mathbb{P}(\text{Ext}^1(\mathcal{J}_Z(1)^D, \mathcal{O}_L(-1))) \).

**Proof.** Let \( \mathcal{F} \) give a point in \( X_{01} \). Recall the resolution from Proposition 3.1.1. We have the isomorphism \( \text{Ker}(\varphi_{11}) \simeq \mathcal{O}(-4) \) and we denote \( \mathcal{C} = \text{Coker}(\varphi_{11}) \). We have \( P_C(t) = t + 3 \), so this sheaf is the direct sum of
a zero-dimensional sheaf and $\mathcal{O}_L(d)$ for a line $L \subset \mathbb{P}^2$ and an integer $d$. It is thus clear that $\mathcal{C}$ has a subsheaf $\mathcal{C}'$ with Hilbert polynomial $P_{\mathcal{C}'}(t) = t + 2$.

Applying the snake lemma to a diagram similar to the first diagram in the proof of Proposition 3.3.2, we obtain an extension

$$0 \longrightarrow \mathcal{O}_C \longrightarrow \mathcal{F} \longrightarrow \mathcal{C} \longrightarrow 0,$$

where $C \subset \mathbb{P}^2$ is a quartic curve. Let $\mathcal{F}' \subset \mathcal{F}$ be the preimage of $\mathcal{C}'$. We have $P_{\mathcal{F}'}(t) = 5t$ and it is easy to see that $\mathcal{F}'$ is semi-stable. We now use the possible resolutions for sheaves in $\mathbb{M}_{\mathbb{P}^2}(5,0)$ found in Section 4, which we obtain independently of any result in this subsection. Taking into account that $H^0(\mathcal{F}' \otimes \Omega^1(1)) = 0$ leaves only two possible resolutions, the ones at Propositions 4.1.2 and 4.1.3. The first resolution must fit into a commutative diagram

$$
\begin{array}{cccc}
0 & \rightarrow & 5\mathcal{O}(-2) & \psi \rightarrow 5\mathcal{O}(-1) \rightarrow \mathcal{F}' \rightarrow 0 \\
\downarrow & & \downarrow \beta & \\
0 & \rightarrow & 4\mathcal{O}(-2) & \varphi \rightarrow 3\mathcal{O}(-1) \oplus \mathcal{O} \rightarrow \mathcal{F} \rightarrow 0
\end{array}
$$

Since $\alpha(1)$ is injective on global sections, we have one of the following two possibilities:

$$\alpha \sim \begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & X & Y & Z
\end{bmatrix} \quad \text{or} \quad \alpha \sim \begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & X & Y
\end{bmatrix}.$$

In the first case $\text{Ker}(\alpha)$ is isomorphic to $\Omega^1$, so the latter is isomorphic to a direct sum of copies of $\mathcal{O}(-2)$. This is absurd. In the second case, we have $\text{Ker}(\beta) \simeq \mathcal{O}(-2)$, hence, without loss of generality, we may assume that $\beta$ is the projection onto the first four terms. From the commutativity of the diagram, we get

$$\psi = \begin{bmatrix}
\varphi_{11} & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & -Y & 0 \\
0 & 0 & 0 & X
\end{bmatrix}.$$

This shows that $\mathcal{F}'$ maps surjectively onto the cokernel of $\varphi_{11}$. But this is impossible because, by construction, the image of $\mathcal{F}'$ in $\mathcal{C}$ is the proper subsheaf $\mathcal{C}'$. Thus far, we have shown that the resolution from Proposition 4.1.2 for $\mathcal{F}'$ is unfeasible. It remains to examine the resolution from Proposition 4.1.3.
This fits into a commutative diagram of the form

$$
\begin{array}{ccccccccc}
0 & \rightarrow & \mathcal{O}(-3) \oplus 2\mathcal{O}(-2) & \rightarrow & 2\mathcal{O}(-1) \oplus \mathcal{O} & \rightarrow & \mathcal{F}' & \rightarrow & 0 \\
\downarrow{\beta} & & \downarrow{\psi} & & \downarrow{\alpha} & & \downarrow & & \\
0 & \rightarrow & 4\mathcal{O}(-2) & \rightarrow & 3\mathcal{O}(-1) \oplus \mathcal{O} & \rightarrow & \mathcal{F} & \rightarrow & 0
\end{array}
$$

Since $\alpha$ and $\alpha(1)$ are injective on global sections, we see that $\alpha$ and $\beta$ are injective and we may write

$$
\beta = \begin{bmatrix}
-\ell_2 & 0 & 0 \\
\ell_1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}, \quad \alpha = \begin{bmatrix}
0 & 0 & 0 \\
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}.
$$

From the commutativity of the diagram and the semi-stability of $\varphi_{11}$, we see that $\ell_1$ and $\ell_2$ are linearly independent one-forms and

$$
\varphi_{11} = \begin{bmatrix}
\ell_1 & \ell_2 & 0 & 0 \\
* & * & \xi_3 & 0 \\
* & * & * & \xi_4
\end{bmatrix}.
$$

We recall that the greatest common divisor of the maximal minors of $\varphi_{11}$ is a linear form $g$. Since $g$ divides both $\ell_1 \det(\xi)$ and $\ell_2 \det(\xi)$, we see that $g$ divides $\det(\xi)$, hence $\xi$ is equivalent to a matrix having a zero-entry. Thus we may write

$$
\varphi_{11} = \begin{bmatrix}
\ell_1 & \ell_2 & 0 & 0 \\
* & * & \xi_3 & 0 \\
* & * & * & \xi_4
\end{bmatrix} = \begin{bmatrix}
\zeta & 0 \\
* & * & \xi_4
\end{bmatrix}.
$$

It is clear that $\zeta$ is semi-stable as a Kronecker $V$-module. Assume that the maximal minors of $\zeta$ have a common linear factor, say $Z$. We may then write

$$
\varphi = \begin{bmatrix}
X & Z & 0 & 0 \\
Y & 0 & Z & 0 \\
* & * & * & S \\
* & * & * & T
\end{bmatrix} = \begin{bmatrix}
\varphi' & 0 \\
0 & S \\
* & * & T
\end{bmatrix}.
$$

Notice that $g$ is a multiple of $Z$, $S$ is non-zero and does not divide $\det(\varphi')/Z$. We have $\text{Coker}(\zeta) \cong \mathcal{O}_L$, where $L \subset \mathbb{P}^2$ is the line with equation $Z = 0$. We
apply the snake lemma to the exact diagram

\[
\begin{array}{ccccccc}
0 & \rightarrow & \mathcal{O}(-2) & \xrightarrow{[S \ T]} & \mathcal{O}(-1) \oplus \mathcal{O} & \rightarrow & 0 \\
0 & \rightarrow & 4\mathcal{O}(-2) & \xrightarrow{\varphi} & 3\mathcal{O}(-1) \oplus \mathcal{O} & \rightarrow & \mathcal{F} & \rightarrow & 0 \\
0 & \rightarrow & \mathcal{O}(-3) & \xrightarrow{\zeta} & 2\mathcal{O}(-1) & \rightarrow & \mathcal{O}_L & \rightarrow & 0 \\
0 & \rightarrow & 0 & \rightarrow & 0 & \rightarrow & 0
\end{array}
\]

in order to obtain a non-split extension of the form

\[
0 \rightarrow \mathcal{G} \rightarrow \mathcal{F} \rightarrow \mathcal{O}_L \rightarrow 0,
\]

where \( \mathcal{G} \) has resolution

\[
0 \rightarrow \mathcal{O}(-3) \oplus \mathcal{O}(-2) \xrightarrow{\psi} \mathcal{O}(-1) \oplus \mathcal{O} \rightarrow \mathcal{G} \rightarrow 0,
\]

with \( \psi_{12} = S \) different from zero. From Proposition 5.2.1 in [4], we see that \( \mathcal{G} \) is in the exceptional divisor of \( \mathbb{M}_{\mathbb{P}^2}(4,0) \). Conversely, any \( \mathcal{G} \) of \( \mathbb{M}_{\mathbb{P}^2}(4,0) \), which is in the exceptional divisor, i.e. satisfying the condition \( h^0(\mathcal{G}) = 1 \), occurs as the cokernel of a morphism \( \psi \) as above with \( \psi_{12} \neq 0 \). Assume now that \( \mathcal{F} \) is an extension of \( \mathcal{O}_L \) with a sheaf \( \mathcal{G} \) as above, satisfying \( H^1(\mathcal{F}) = 0 \). Choose an equation \( Z = 0 \) for \( L \). We combine the resolution of \( \mathcal{G} \) with the resolution

\[
0 \rightarrow \mathcal{O}(-3) \rightarrow 3\mathcal{O}(-2) \xrightarrow{\zeta} 2\mathcal{O}(-1) \rightarrow \mathcal{O}_L \rightarrow 0
\]

and we obtain a resolution

\[
0 \rightarrow \mathcal{O}(-3) \rightarrow \mathcal{O}(-3) \oplus 4\mathcal{O}(-2) \rightarrow 3\mathcal{O}(-1) \oplus \mathcal{O} \rightarrow \mathcal{F} \rightarrow 0.
\]

The morphism \( \mathcal{O}(-3) \rightarrow \mathcal{O}(-3) \) in the above complex is non-zero because, by hypothesis, \( H^1(\mathcal{F}) \) vanishes. Thus, we may cancel \( \mathcal{O}(-3) \) to get a resolution as in Proposition 3.1.1 with

\[
\varphi = \begin{bmatrix}
\zeta & 0 \\
0 & \psi_{12} \\
\psi_{22}
\end{bmatrix}
\]

In view of Proposition 3.3.5, the condition that \( \mathcal{F} \) be in \( X_{01} \) is equivalent to saying that \( \det(\varphi')/Z, \psi_{12}X, \psi_{12}Y, \psi_{12}Z \) are linearly independent two-forms.
This defines an open subset inside the closed set of extension sheaves of $\mathcal{O}_L$ by $\mathcal{G}$ with vanishing first cohomology.

It remains to examine the case when the maximal minors of $\zeta$ have no common factor. Then $g$ is a multiple of $\xi_4$. We have $\text{Ker}(\zeta) \cong \mathcal{O}(-4)$. According to Propositions 4.5 and 4.6 in [2], the cokernel of $\zeta$ is isomorphic to the structure sheaf of a zero-dimensional scheme $Z$ of length 3 not contained in a line. Write as above

$$
\varphi = \begin{bmatrix}
\zeta & 0 \\
0 & \\
\ast & \ast & \ast & S \\
\ast & \ast & \ast & T
\end{bmatrix}
$$

and note that the snake lemma gives an extension

$$
0 \longrightarrow \mathcal{E} \longrightarrow \mathcal{F} \longrightarrow \mathcal{O}_Z \longrightarrow 0,
$$

where $\mathcal{E}$ has a resolution

$$
0 \longrightarrow \mathcal{O}(-4) \oplus \mathcal{O}(-2) \overset{\psi}{\longrightarrow} \mathcal{O}(-1) \oplus \mathcal{O} \longrightarrow \mathcal{E} \longrightarrow 0
$$

in which $\psi_{12} = S$ and $\psi_{22} = T$. We have $P_{\mathcal{E}}(t) = 5t - 2$. According to Proposition 2.1.4, $\mathcal{E}$ is in $\mathbb{M}_{\mathbb{P}^2}(5,-2)$ precisely if $S$ does not divide $T$. In that case $\mathcal{E}(1)$ gives a point in the stratum $X_3$ of $\mathbb{M}_{\mathbb{P}^2}(5,3)$. Finally, assume that $S$ divides $T$. We have a non-split extension of sheaves

$$
0 \longrightarrow \mathcal{O}_L(-1) \longrightarrow \mathcal{F} \longrightarrow \mathcal{S} \longrightarrow 0,
$$

where $L \subset \mathbb{P}^2$ is given by the equation $S = 0$ and $\mathcal{S}$ has a resolution of the form

$$
0 \longrightarrow 3\mathcal{O}(-2) \overset{\psi}{\longrightarrow} 2\mathcal{O}(-1) \oplus \mathcal{O} \longrightarrow \mathcal{S} \longrightarrow 0,
$$

where $\psi_{11} = \zeta$. According to Proposition 3.3.2 in [4], the subset of $\mathbb{M}_{\mathbb{P}^2}(4,3)$ of sheaves of the form $\mathcal{S}^\nu(1)$ is an open subset consisting of all sheaves of the form $\mathcal{J}_Z(2)$, where $Z \subset \mathbb{P}^2$ is a zero-dimensional scheme of length 3 not contained in a line, contained in a quartic curve $C \subset \mathbb{P}^2$ and $\mathcal{J}_Z \subset \mathcal{O}_C$ is its ideal sheaf. Assume we are given $\mathcal{S}$ as above, $L \subset \mathbb{P}^2$ a line with equation $S = 0$ and $\mathcal{F}$ a non-split extension of $\mathcal{S}$ by $\mathcal{O}_L(-1)$. We combine the above resolution for $\mathcal{S}$ with the standard resolution of $\mathcal{O}_L(-1)$ to get a resolution for $\mathcal{F}$ as in Proposition 3.1.1. By Proposition 3.3.5, the condition that $\mathcal{F}$ be in $X_{01}$ is equivalent to saying that $S$ divides $\det(\varphi')$ and $\det(\varphi')/S$ together with the maximal minors of $\zeta$ form a linearly independent set in $S^2V^*$. These conditions define a locally closed subset of $\mathbb{P}(\text{Ext}^1(\mathcal{S}, \mathcal{O}_L(-1)))$.

From what was said above, we can summarise the following proposition.

**Proposition 3.3.7.** \{ $X_0, X_1, X_2, X_3$ \} represents a stratification of $\mathbb{M}_{\mathbb{P}^2}(5,1)$ by locally closed irreducible subvarieties of codimension 0, 2, 3, 5.
4. Euler characteristic zero

4.1. Locally free resolutions for semi-stable sheaves.

**Proposition 4.1.1.** Every sheaf $\mathcal{F}$ giving a point in $\mathcal{M}_{\mathbb{P}^2}(5,0)$ and satisfying the condition $h^0(\mathcal{F}(-1)) > 0$ is of the form $\mathcal{O}_C(1)$ for a quintic curve $C \subset \mathbb{P}^2$.

*Proof.* Consider a non-zero morphism $\mathcal{O} \to \mathcal{F}(-1)$. As in the proof of Proposition 2.1.3 in [4], it factors through an injective map $\mathcal{O}_C \to \mathcal{F}(-1)$. Here $C \subset \mathbb{P}^2$ is a curve; its degree must be 5, otherwise $\mathcal{O}_C$ would destabilise $\mathcal{F}(-1)$. As both $\mathcal{O}_C$ and $\mathcal{F}(-1)$ have the same Hilbert polynomial, the injective morphism from above must be an isomorphism.

The converse follows from the general fact that the structure sheaf of a curve in $\mathbb{P}^2$ is stable. $\square$

**Proposition 4.1.2.** The sheaves $\mathcal{F}$ giving points in $\mathcal{M}_{\mathbb{P}^2}(5,0)$ and satisfying the condition $h^1(\mathcal{F}) = 0$ are precisely the sheaves with resolution

$$0 \longrightarrow 5\mathcal{O}(-2) \xrightarrow{\varphi} 5\mathcal{O}(-1) \longrightarrow \mathcal{F} \longrightarrow 0.$$  

Moreover, such a sheaf $\mathcal{F}$ is properly semi-stable if and only if $\varphi$ is equivalent to a morphism of the form

$$\begin{bmatrix} \ast & \psi \\ \ast & 0 \end{bmatrix}$$

for some $\psi : m\mathcal{O}(-2) \longrightarrow m\mathcal{O}(-1)$, $1 \leq m \leq 4$.

*Proof.* Assume that $\mathcal{F}$ gives a point in $\mathcal{M}_{\mathbb{P}^2}(5,0)$ and its first cohomology vanishes. For a suitable line $L \subset \mathbb{P}^2$, we have an exact sequence

$$0 \longrightarrow \mathcal{F} \longrightarrow \mathcal{F}(1) \longrightarrow \mathcal{F}(1)|_L \longrightarrow 0.$$  

The associated long cohomology sequence shows that $H^1(\mathcal{F}(1))$ vanishes, too. The same argument applied to the exact sequence

$$0 \longrightarrow \mathcal{F}(-1) \longrightarrow \mathcal{F} \otimes \mathcal{V} \longrightarrow \mathcal{F} \otimes \Omega^1(2) \longrightarrow 0$$

shows that $H^1(\mathcal{F} \otimes \Omega^1(2)) = 0$. The Beilinson free monad (2.2.1) in [4] for $\mathcal{F}(1)$ gives the resolution

$$0 \longrightarrow 5\mathcal{O}(-1) \longrightarrow 5\mathcal{O} \longrightarrow \mathcal{F}(1) \longrightarrow 0.$$  

Conversely, assume that $\mathcal{F}$ is the cokernel of a morphism $\varphi$ as in the proposition. Trivially, $\mathcal{F}$ has no zero-dimensional torsion, because it has a locally free resolution of length 1. For any subsheaf $\mathcal{F}' \subset \mathcal{F}$, we have $H^0(\mathcal{F}') = 0$ because the corresponding cohomology group for $\mathcal{F}$ vanishes. We get $\chi(\mathcal{F}') \leq 0$, hence $p(\mathcal{F}') \leq 0 = p(\mathcal{F})$ and we conclude that $\mathcal{F}$ is semi-stable.

To finish the proof, we must show that for properly semi-stable sheaves $\mathcal{F}$ the morphism $\varphi$ has the special form given in the proposition. Consider
a proper subsheaf $\mathcal{F}' \subset \mathcal{F}$ which gives a point in $M_{\mathbb{P}^2}(m,0)$, $1 \leq m \leq 4$. As noted, $H^0(\mathcal{F}')$ vanishes, hence also $H^1(\mathcal{F}')$ vanishes and, repeating the above steps with $\mathcal{F}'$ instead of $\mathcal{F}$, we arrive at the resolution

$$0 \longrightarrow m\mathcal{O}(-2) \overset{\psi}{\longrightarrow} m\mathcal{O}(-1) \longrightarrow \mathcal{F}' \longrightarrow 0.$$  

This fits into a commutative diagram of the form

$$
\begin{array}{ccc}
0 & \longrightarrow & m\mathcal{O}(-2) \\
\downarrow{\beta} & & \downarrow{\alpha} \\
0 & \longrightarrow & 5\mathcal{O}(-2) \\
\downarrow{\varphi} & & \downarrow{\alpha} \\
0 & \longrightarrow & 5\mathcal{O}(-1) \\
\downarrow{\varphi} & & \downarrow{\alpha} \\
0 & \longrightarrow & \mathcal{F} \\
\downarrow{\varphi} & & \downarrow{\alpha} \\
0 & \longrightarrow & 0
\end{array}
$$

Since $\alpha(1)$ is injective on global sections we see that $\alpha$, hence also $\beta$, are injective. Thus, $\varphi$ has the required special form. □

**Proposition 4.1.3.** The sheaves $\mathcal{F}$ giving points in $M_{\mathbb{P}^2}(5,0)$ and satisfying the cohomological conditions $h^0(\mathcal{F}(-1)) = 0$ and $h^1(\mathcal{F}) = 1$ are precisely the sheaves with resolution

$$0 \longrightarrow \mathcal{O}(-3) \oplus 2\mathcal{O}(-2) \overset{\varphi}{\longrightarrow} 2\mathcal{O}(-1) \oplus \mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0,$$

where $\varphi_{12} : 2\mathcal{O}(-2) \rightarrow 2\mathcal{O}(-1)$ is an injective morphism.

**Proof.** The Beilinson free monad (2.2.1) in [4] for $\mathcal{F}$ reads as follows:

$$0 \longrightarrow 5\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \longrightarrow (m+5)\mathcal{O}(-1) \oplus \mathcal{O} \longrightarrow \mathcal{O} \longrightarrow 0.$$  

From this, we obtain the exact sequences

$$0 \longrightarrow 5\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \longrightarrow \Omega^1 \oplus (m+2)\mathcal{O}(-1) \oplus \mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0$$

and

$$0 \longrightarrow \mathcal{O}(-3) \oplus 5\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \longrightarrow 3\mathcal{O}(-2) \oplus (m+2)\mathcal{O}(-1) \oplus \mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0,$$

with $\varphi_{13} = 0$, $\varphi_{23} = 0$. As in the proof of Proposition 2.1.4, we see that $\text{rank}(\varphi_{12}) = 3$, so we may cancel $3\mathcal{O}(-2)$ to get the resolution

$$0 \longrightarrow \mathcal{O}(-3) \oplus 2\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \overset{\varphi}{\longrightarrow} (m+2)\mathcal{O}(-1) \oplus \mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0,$$

with $\varphi_{13} = 0$. By the injectivity of $\varphi$ we must have $m \leq 1$. If $m = 1$, then $\mathcal{F}$ has a subsheaf of the form $\mathcal{O}_L$, for a line $L \subset \mathbb{P}^2$, contrary to semi-stability. We conclude that $m = 0$ and we obtain a resolution as in the proposition. If $\varphi_{12}$ were not injective, then $\varphi_{12}$ would be equivalent to a morphism represented by a matrix with a zero-row or a zero-column. Thus, $\mathcal{F}$ would have a destabilising subsheaf of the form $\mathcal{O}_C$ or a destabilising quotient sheaf of the form $\mathcal{O}_C(-1)$ for a conic curve $C \subset \mathbb{P}^2$.

Conversely, we assume that $\mathcal{F}$ has a resolution as in the proposition and we need to show that there are no destabilising subsheaves $\mathcal{E}$. Such a subsheaf
must satisfy $h^0(\mathcal{E}) = 1$, $h^1(\mathcal{E}) = 0$, $P_\mathcal{E}(t) = mt + 1$, $1 \leq m \leq 4$. Moreover, $H^0(\mathcal{E}(-1))$ and $H^0(\mathcal{E} \otimes \Omega^1(1))$ vanish because the corresponding cohomology groups for $\mathcal{F}$ vanish. We can now write the Beilinson free monad for $\mathcal{E}$. We get a resolution that fits into a commutative diagram

$$
\begin{array}{ccc}
0 & \longrightarrow & (m-1)\mathcal{O}(-2) \\
\psi & \longrightarrow & (m-2)\mathcal{O}(-1) \oplus \mathcal{O} \\
\beta & \longrightarrow & \mathcal{E} \\
\alpha & \longrightarrow & 0 \\
0 & \longrightarrow & \mathcal{O}(-3) \oplus 2\mathcal{O}(-2) \\
\varphi & \longrightarrow & 2\mathcal{O}(-1) \oplus \mathcal{O} \\
\phi & \longrightarrow & \mathcal{F} \\
\end{array}
$$

Since $\alpha$ and $\alpha(1)$ are injective on global sections, we see that $\alpha$ is injective, forcing $\beta$ to be injective, too. Thus, $m = 2$ or $m = 3$. In both cases, $\varphi_{12}$ fails to be injective, contradicting our hypothesis.

**Proposition 4.1.4.** The sheaves $\mathcal{F}$ giving points in $\mathbb{P}_2^5(5,0)$ and satisfying the cohomological conditions $h^0(\mathcal{F}(-1)) = 0$ and $h^1(\mathcal{F}) = 2$ are precisely the sheaves with resolution

$$
0 \longrightarrow 2\mathcal{O}(-3) \oplus \mathcal{O}(-1) \stackrel{\varphi}{\longrightarrow} \mathcal{O}(-2) \oplus 2\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0
$$

such that $\varphi_{11}$ has linearly independent entries and, likewise, $\varphi_{22}$ has linearly independent entries.

**Proof.** Let $\mathcal{F}$ give a point in $\mathbb{P}_2^5(5,0)$ and satisfy the conditions from the proposition. The Beilinson free monad for $\mathcal{F}$ reads

$$
0 \longrightarrow 5\mathcal{O}(-2) \oplus m\mathcal{O}(-1) \longrightarrow (m+5)\mathcal{O}(-1) \oplus 2\mathcal{O} \longrightarrow 2\mathcal{O} \longrightarrow 0.
$$

Dualising and tensoring with $\mathcal{O}(1)$ we get the following resolution for the sheaf $\mathcal{G} = \mathcal{F}^D(1)$, which gives a point in $\mathbb{P}_2^5(5,5)$:

$$
0 \longrightarrow 2\mathcal{O}(-2) \stackrel{\eta}{\longrightarrow} 2\mathcal{O}(-2) \oplus (m+5)\mathcal{O}(-1) \stackrel{\varphi}{\longrightarrow} m\mathcal{O}(-1) \oplus 5\mathcal{O} \longrightarrow \mathcal{G} \longrightarrow 0,
$$

$\eta = \begin{bmatrix} 0 \\ \psi \end{bmatrix}$.

Here $\varphi_{12} = 0$. As $\mathcal{G}$ has rank zero and maps surjectively onto $\mathcal{C} = \text{Coker}(\varphi_{11})$, we see that $m \leq 2$. If $m = 2$, then $\varphi_{11}$ must be injective, otherwise $\mathcal{C}$ will have positive rank. We get $P_\mathcal{C}(t) = 2t$, hence $\mathcal{C}$ destabilises $\mathcal{G}$. The case $m = 0$ can be eliminated as in the proof of Proposition 3.1.3. Thus, $m = 1$. As in the proof of Proposition 3.2.5, we may assume that $\psi$ is represented by the matrix

$$
\begin{bmatrix}
X & Y & Z & 0 & 0 & 0 \\
0 & 0 & 0 & X & Y & Z
\end{bmatrix}^T.
$$

From the Beilinson monad for $\mathcal{F}$, we obtain the resolution

$$
0 \longrightarrow 5\mathcal{O}(-2) \oplus \mathcal{O}(-1) \longrightarrow 2\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0,
$$

which, combined with the standard resolution for $\mathcal{O}^1$, yields the exact sequence

$$
0 \longrightarrow 2\mathcal{O}(-3) \oplus 5\mathcal{O}(-2) \oplus \mathcal{O}(-1) \stackrel{\varphi}{\longrightarrow} 6\mathcal{O}(-2) \oplus 2\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0.
$$
Note that \( \mathcal{F} \) maps surjectively onto \( \text{Coker}(\varphi_{11}, \varphi_{12}) \), so this sheaf is supported on a curve, forcing \( \text{rank}(\varphi_{12}) \geq 4 \). If \( \text{rank}(\varphi_{12}) = 4 \), then \( \text{Coker}(\varphi_{11}, \varphi_{12}) \) would have Hilbert polynomial \( P(t) = 2t - 2 \), so it would destabilise \( \mathcal{F} \). We deduce that \( \text{rank}(\varphi_{12}) = 5 \), so we may cancel \( 5 \mathcal{O}(2) \) to get a resolution as in the proposition. If the entries of \( \varphi_{12} \) were linearly dependent, then \( \mathcal{F} \) would have a destabilising quotient sheaf of the form \( \mathcal{O}_L(2) \) for a line \( L \subset \mathbb{P}^2 \). If the entries of \( \varphi_{22} \) were linearly dependent, then \( \mathcal{F} \) would have a destabilising subsheaf of the form \( \mathcal{O}_L \).

Conversely, we assume that \( \mathcal{F} \) has a resolution as in the proposition and we need to show that there is no destabilising subsheaf. Let \( \mathcal{F}' \subset \mathcal{F} \) be a non-zero subsheaf of multiplicity at most 4. We shall use the extension

\[
0 \to \mathcal{J}_x(1) \to \mathcal{F} \to \mathcal{F}' \cap \mathcal{J}_x(1) \to 0
\]

from Proposition 4.3.2. Denote by \( \mathcal{C}' \) the image of \( \mathcal{F}' \) in \( \mathbb{C}_x \) and put \( \mathcal{K} = \mathcal{F}' \cap \mathcal{J}_x(1) \). Let \( \mathcal{A} \) and \( \mathcal{O}_S \) be as in the proof of Proposition 3.1.2. Recall that \( S \) is a curve of degree \( d \leq 4 \). We can estimate the slope of \( \mathcal{F}' \) as in the proof of Proposition 3.1.2 and we get

\[
p(\mathcal{F}') = -\frac{d}{2} + \frac{h^0(\mathcal{C}') - h^0(\mathcal{A}/\mathcal{K})}{5 - d} \leq -\frac{d}{2} + \frac{1}{5 - d} < 0 = p(\mathcal{F}).
\]

We conclude that \( \mathcal{F} \) is semi-stable. \( \square \)

Let \( X_i, i = 0, 1, 2, 3 \), be the subset of \( M_{\mathbb{P}^2}(5,0) \) of stable-equivalence classes of sheaves \( \mathcal{F} \) as in Propositions 4.1.2, 4.1.3, 4.1.4, respectively, Proposition 4.1.1.

**Proposition 4.1.5.** The subsets \( X_0, X_1, X_2, X_3 \) are disjoint. The subset of \( M_{\mathbb{P}^2}(5,0) \) of stable-equivalence classes of properly semi-stable sheaves is included in \( X_0 \cup X_1 \).

**Proof.** Let \( \mathcal{F} \) be a properly semi-stable sheaf in \( M_{\mathbb{P}^2}(5,0) \). We have an exact sequence

\[
0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0,
\]

with \( \mathcal{F}' \) giving a point in \( M_{\mathbb{P}^2}(r,0) \), \( \mathcal{F}'' \) giving a point in \( M_{\mathbb{P}^2}(s,0) \), \( r + s = 5 \). From the description of \( M_{\mathbb{P}^2}(r,0) \), \( 1 \leq r \leq 4 \), found in [4], we have the relations

\[
h^0(\mathcal{F}') = 0 \quad \text{if} \quad r = 1, 2, \quad h^0(\mathcal{F}') \leq 1 \quad \text{if} \quad r = 3, 4.
\]

In all possible situations we get \( h^0(\mathcal{F}) \leq 1 \), hence the stable-equivalence class of \( \mathcal{F} \) is in \( X_0 \cup X_1 \). Thus all sheaves in \( X_2 \) and \( X_3 \) are stable, so \( X_2 \) is disjoint from the other \( X_i \) and the same is true for \( X_3 \). It remains to show that \( X_0 \) and \( X_1 \) are disjoint. Let \( \mathcal{F} \) be a properly semi-stable sheaf as in Proposition 4.1.2 and let \( \mathcal{G} \) be a sheaf in the same class of stable-equivalence as \( \mathcal{F} \). Let \( \mathcal{F}' \) be one of the terms of a Jordan–Hölder filtration of \( \mathcal{F} \). From the proof of Proposition 4.1.2, it transpires that \( \mathcal{F}' \) has resolution

\[
0 \to m\mathcal{O}(2) \to m\mathcal{O}(1) \to \mathcal{F}' \to 0
\]

Let \( X_i, i = 0, 1, 2, 3 \), be the subset of \( M_{\mathbb{P}^2}(5,0) \) of stable-equivalence classes of sheaves \( \mathcal{F} \) as in Propositions 4.1.2, 4.1.3, 4.1.4, respectively, Proposition 4.1.1.
for some integer $1 \leq m \leq 4$. Thus, $H^0(\mathcal{F}') = 0$. Any term of a Jordan–Hölder filtration of $\mathcal{G}$ is also a term of a Jordan–Hölder filtration of $\mathcal{F}$, hence its group of global sections vanishes. We deduce that $H^0(\mathcal{G}) = 0$. Thus, $\mathcal{F}$ cannot give a point in $X_1$. \hfill \Box

**Proposition 4.1.6.** There are no sheaves $\mathcal{F}$ giving points in $M_{\mathbb{P}^2}(5,0)$ and satisfying the cohomological conditions $h^0(\mathcal{F}(-1)) = 0$ and $h^1(\mathcal{F}) \geq 3$.

**Proof.** In view of Proposition 4.1.5, we may restrict our attention to stable sheaves $\mathcal{F}$ in $M_{\mathbb{P}^2}(5,0)$. Suppose that $\mathcal{F}$ satisfies $h^0(\mathcal{F}(-1)) = 0$ and $h^1(\mathcal{F}) \neq 0$. Consider a non-zero morphism $\mathcal{O} \to \mathcal{F}$. As in the proof of Proposition 2.1.3 in [4], this must factor through an injective morphism $\mathcal{O}_C \to \mathcal{F}$, where $C \subset \mathbb{P}^2$ is a curve. From the stability of $\mathcal{F}$, we see that $C$ can only have degree 4 or 5.

Assume that $C$ has degree 5. The quotient sheaf $\mathcal{C} = \mathcal{F}/\mathcal{O}_C$ is supported on finitely many points and has length 5. Take a subsheaf $\mathcal{C}' \subset \mathcal{C}$ of length 4, and let $\mathcal{F}'$ be its preimage in $\mathcal{F}$. We get an exact sequence

$$0 \longrightarrow \mathcal{F}' \longrightarrow \mathcal{F} \longrightarrow \mathcal{C}_x \longrightarrow 0,$$

where $\mathcal{C}_x$ is the structure sheaf of a point. Any destabilising subsheaf of $\mathcal{F}'$ would ruin the stability of $\mathcal{F}$, hence $\mathcal{F}'$ is in $M_{\mathbb{P}^2}(5,-1)$. From Section 3.1, we know that $h^0(\mathcal{F}') \leq 2$, hence $h^0(\mathcal{F}) \leq 2$ unless $h^0(\mathcal{F}') = 2$ and the morphism $\mathcal{F} \to \mathcal{C}_x$ is surjective on global sections. In this case, we can apply the horseshoe lemma to the above extension, to the standard resolution of $\mathcal{C}_x$ and to the resolution

$$0 \longrightarrow \mathcal{O}(-4) \oplus \mathcal{O}(-1) \longrightarrow 2\mathcal{O} \longrightarrow \mathcal{F}' \longrightarrow 0.$$

We obtain a resolution

$$0 \longrightarrow \mathcal{O}(-2) \longrightarrow \mathcal{O}(-4) \oplus 3\mathcal{O}(-1) \overset{\varphi}{\longrightarrow} 3\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0,$$

which yields an exact sequence

$$0 \longrightarrow \mathcal{O}(-4) \longrightarrow \text{Coker}(\varphi_{12}) \longrightarrow \mathcal{F} \longrightarrow 0.$$

We claim that the morphism $\mathcal{O}(-2) \to 3\mathcal{O}(-1)$ in the above resolution is equivalent to the morphism represented by the matrix

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix}.$$

The argument uses the fact that $\mathcal{F}$ has no zero-dimensional torsion and is analogous to the proof that the vector space $H$ at Proposition 2.1.4 has dimension 3. We can now describe $\varphi_{12}$. We claim that $\varphi_{12}$ is equivalent to the
morphism represented by the matrix
\[
\begin{bmatrix}
-Y & X & 0 \\
-Z & 0 & X \\
0 & -Y & Z
\end{bmatrix}.
\]
The argument, we recall from the proof of Proposition 3.1.3, uses the fact that the map $3\mathcal{O} \to \mathcal{F}$ is injective on global sections and the fact that the only morphism $\mathcal{O}_L(1) \to \mathcal{F}$ for any line $L \subset \mathbb{P}^2$ is the zero-morphism. We deduce that $\text{Coker}(\varphi_{12})$ is isomorphic to $\mathcal{O}(1)$. We obtain $h^0(\mathcal{F}(-1)) = 1$, contradicting our hypothesis.

Assume now that $C$ has degree 4. The zero-dimensional torsion $C'$ of the quotient sheaf $\mathcal{C} = \mathcal{F}/\mathcal{O}_C$ has length at most 1, otherwise its preimage in $\mathcal{F}$ would violate stability. Assume that $C'$ has length 1. Let $\mathcal{F}'$ be its preimage in $\mathcal{F}$. We have an extension
\[
0 \longrightarrow \mathcal{F}' \longrightarrow \mathcal{F} \longrightarrow \mathcal{O}_L \longrightarrow 0.
\]
Here $L \subset \mathbb{P}^2$ is a line and it is easy to see that $\mathcal{F}'$ gives a point in $\mathbb{M}_{\mathbb{P}^2}(4, -1)$. From the description of $\mathbb{M}_{\mathbb{P}^2}(4, 1)$ found in [4], we know that $h^0(\mathcal{F}') \leq 1$, hence $h^0(\mathcal{F}) \leq 2$.

Assume, finally, that $C$ has no zero-dimensional torsion. Then $C \simeq \mathcal{O}_L(1)$ for a line $L \subset \mathbb{P}^2$. We have $h^0(\mathcal{F}) \leq 2$ unless the morphism $\mathcal{F} \to \mathcal{O}_L(1)$ is surjective on global sections. In that case, we can apply the horseshoe lemma to the extension
\[
0 \longrightarrow \mathcal{O}_C \longrightarrow \mathcal{F} \longrightarrow \mathcal{O}_L(1) \longrightarrow 0,
\]
to the standard resolution of $\mathcal{O}_C$ and, fixing an equation for $L$, say $X = 0$, to the resolution
\[
0 \longrightarrow \mathcal{O}(-2) \xrightarrow{\eta} 3\mathcal{O}(-1) \xrightarrow{\xi} 2\mathcal{O} \longrightarrow \mathcal{O}_L(1) \longrightarrow 0,
\]
where
\[
\eta = \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}, \quad \xi = \begin{bmatrix} -Y & X & 0 \\ -Z & 0 & X \end{bmatrix}.
\]
We obtain the exact sequence
\[
0 \longrightarrow \mathcal{O}(-2) \longrightarrow \mathcal{O}(-4) \oplus 3\mathcal{O}(-1) \longrightarrow 3\mathcal{O} \longrightarrow \mathcal{F} \longrightarrow 0.
\]
We saw above that this leads to the relation $h^0(\mathcal{F}(-1)) = 1$, which is contrary to our hypothesis.

4.2. Description of the strata as quotients. In Section 4.1, we found that the moduli space $\mathbb{M}_{\mathbb{P}^2}(5, 0)$ can be decomposed into four strata:

- an open stratum $X_0$ given by the condition $h^1(\mathcal{F}) = 0$;
- a locally closed stratum $X_1$ of codimension 1 given by the conditions $h^0(\mathcal{F}(-1)) = 0, \quad h^1(\mathcal{F}) = 1$;
− a locally closed stratum $X_2$ of codimension 4 given by the conditions 
\[ h^0(\mathcal{F}(-1)) = 0, \quad h^1(\mathcal{F}) = 2; \]

− the closed stratum $X_3$ given by the condition $h^0(\mathcal{F}(-1)) > 0$, consisting of sheaves of the form $\mathcal{O}_C(1)$, where $C \subset \mathbb{P}^2$ is a quintic curve. Clearly, $X_3$ is isomorphic to $\mathbb{P}(S^5V^*)$.

In the sequel, $X_i$ will be equipped with the canonical reduced structure induced from $\mathbb{M}_{\mathbb{P}^2}(5,0)$. Let $W_0$, $W_1$, $W_2$ be the sets of morphisms $\varphi$ from Propositions 4.1.2, 4.1.3, respectively Proposition 4.1.4. Each sheaf $\mathcal{F}$ giving a point in $X_i$, $i = 0, 1, 2$, is the cokernel of a morphism $\varphi \in W_i$. Let $W_i$ be the ambient vector spaces of homomorphisms of sheaves containing $W_i$, for example, $W_0 = \text{Hom}(5\mathcal{O}(-2), 5\mathcal{O}(-1))$. Let $G_i$ be the natural groups of automorphisms acting by conjugation on $W_i$. In this subsection, we shall prove that there exist a good quotient $W_0//G_0$, a categorical quotient of $W_1$ by $G_1$ and a geometric quotient $W_2/G_2$. We shall prove that each quotient is isomorphic to the corresponding subvariety $X_i$. We shall give concrete descriptions of $W_0//G_0$ and $W_2/G_2$.

**Proposition 4.2.1.** There exists a good quotient $W_0//G_0$ and it is a proper open subset inside $\mathbb{N}(3,5,5)$. Moreover, $W_0//G_0$ is isomorphic to $X_0$. In particular, $\mathbb{M}_{\mathbb{P}^2}(5,0)$ and $\mathbb{N}(3,5,5)$ are birational.

**Proof.** Let $W_0^{ss} \subset W_0$ denote the subset of morphisms that are semi-stable for the action of $G_0$. This group is reductive, so by the classical geometric invariant theory there is a good quotient $W_0^{ss}//G_0$, which is nothing but the Kronecker moduli space $\mathbb{N}(3,5,5)$. According to King's criterion of semi-stability $[7]$, a morphism $\varphi \in W_0$ is semi-stable if and only if it is not in the $G_0$-orbit of a morphism of the form

\[
\begin{bmatrix}
* & \psi \\
* & 0
\end{bmatrix}
\]

for some $\psi : (m+1)\mathcal{O}(-2) \longrightarrow m\mathcal{O}(-1), \quad 0 \leq m \leq 4$.

It is now clear that $W_0$ is the subset of injective morphisms inside $W_0^{ss}$, so it is open and $G_0$-invariant. In point of fact, it is easy to check that $W_0$ is the preimage in $W_0^{ss}$ of a proper open subset inside $W_0^{ss}//G_0$. This subset is the good quotient of $W_0$ by $G_0$.

We shall now prove the injectivity of the canonical map $W_0//G_0 \rightarrow X_0$. Consider the map $\nu : W_0 \rightarrow X_0$ sending $\varphi$ to the stable-equivalence class of its cokernel. Consider a properly semi-stable sheaf $\mathcal{F} = \text{Coker}(\varphi), \varphi \in W_0$, giving a point $[\mathcal{F}]$ in $X_0$. For simplicity of notations, we assume that $\mathcal{F}$ has a Jordan–Hölder filtration of length 2, that is, there is an extension

\[ 0 \longrightarrow \mathcal{F}' \longrightarrow \mathcal{F} \longrightarrow \mathcal{F}'' \longrightarrow 0 \]
of stable sheaves $\mathcal{F}' \in \text{M}_{\mathbb{P}^2}(r, 0)$ and $\mathcal{F}'' \in \text{M}_{\mathbb{P}^2}(s, 0)$. From the proof of Proposition 4.1.2, we see that there are resolutions

$$
0 \longrightarrow r\mathcal{O}(-2) \xrightarrow{\varphi'} r\mathcal{O}(-1) \longrightarrow \mathcal{F}' \longrightarrow 0,
$$

$$
0 \longrightarrow s\mathcal{O}(-2) \xrightarrow{\varphi''} s\mathcal{O}(-1) \longrightarrow \mathcal{F}'' \longrightarrow 0.
$$

Using the horseshoe lemma, we see that $\varphi$ is in the orbit of a morphism represented by a matrix of the form

$$
\begin{bmatrix}
\varphi'' & 0 \\
\ast & \varphi'
\end{bmatrix}.
$$

It is clear that $\varphi'' \oplus \varphi'$ is in the closure of the orbit of $\varphi$. Thus, $\nu^{-1}([\mathcal{F}])$ is a union of orbits, each containing $\varphi'' \oplus \varphi'$ in its closure. It follows that the preimage of $[\mathcal{F}]$ in $W_0//G_0$ is a point. Thus far, we have proved that the canonical map $W_0//G_0 \to X_0$ is bijective. To show that it is an isomorphism, we use the method of Theorem 3.1.6 in [4]. We must produce a resolution as in Proposition 4.1.2 starting from the Beilinson spectral sequence for $\mathcal{F}$. Diagram (2.2.3) in [4] for $\mathcal{F}$ reads

$$
\begin{array}{ccc}
5\mathcal{O}(-2) & \xrightarrow{\varphi_1} & 5\mathcal{O}(-1) \\
\downarrow & & \downarrow \\
0 & & 0
\end{array}
$$

From the exact sequence (2.2.5) in [4], we deduce that $\varphi_1$ is injective and its cokernel is isomorphic to $\mathcal{F}$. □

**Proposition 4.2.2.** There exists a categorical quotient of $W_1$ modulo $G_1$, which is isomorphic to $X_1$.

**Proof.** Let $\nu : W_1 \to X_1$ be the canonical map sending a morphism $\varphi$ to the stable-equivalence class of its cokernel. As in the proof of Proposition 4.2.1, one can check that the preimage of an arbitrary point in $X_1$ under $\nu$ is a union of $G_1$-orbits whose closures have non-empty intersection. This shows that $\nu$ is bijective. To show that $\nu$ is a categorical quotient map we proceed as at Theorem 3.1.6 in [4]. Given $\mathcal{F}$ in $X_1$, we need to produce a resolution as in Proposition 4.1.3 starting from the Beilinson spectral sequence. We shall work, instead, with the dual sheaf $\mathcal{G} = \mathcal{F}^! (1)$, which gives a point in $\text{M}_{\mathbb{P}^2}(5, 5)$. Diagram (2.2.3) in [4] for $\mathcal{G}$ takes the form

$$
\begin{array}{ccc}
\mathcal{O}(-2) & \xrightarrow{\varphi_3} & 5\mathcal{O}(-1) \\
\downarrow & \varphi_4 & \downarrow \\
\mathcal{O}(-2) & \xrightarrow{\varphi_3} & 5\mathcal{O}
\end{array}
$$
The exact sequence (2.2.5) in [4] reads
\[ 0 \rightarrow \mathcal{O}(-2) \rightarrow \text{Coker}(\varphi_4) \rightarrow \mathcal{G} \rightarrow 0. \]
Repeating the arguments from the proof of Proposition 3.2.4 it is easy to see that we may write
\[ \varphi_3 = \begin{bmatrix} X \\ Y \\ Z \\ 0 \end{bmatrix} \quad \text{and} \quad \varphi_4 = \begin{bmatrix} -Y & X & 0 & * & * \\ -Z & 0 & X & * & * \\ 0 & -Z & Y & * & * \\ 0 & 0 & 0 & \psi_{11} & \psi_{12} \\ 0 & 0 & 0 & \psi_{21} & \psi_{22} \end{bmatrix}. \]
If the morphism \( \psi : 2\mathcal{O}(-1) \rightarrow 2\mathcal{O} \) represented by the matrix \( (\psi_{ij})_{1 \leq i,j \leq 2} \) were not injective, then \( \psi \) would be equivalent to a morphism represented by a matrix with a zero-row or a zero-column. From the snake lemma, it would follow that \( \text{Coker}(\varphi_4) \) has a subsheaf \( \mathcal{S} \) with Hilbert polynomial \( P(t) = 3t + 4 \) or \( 2t + 3 \). This sheaf would map injectively to \( \mathcal{G} \) because \( \mathcal{S} \cap \mathcal{O}(-2) = \{0\} \). The semi-stability of \( \mathcal{G} \) would be violated. We deduce that \( \psi \) is injective and we obtain the extension
\[ 0 \rightarrow \mathcal{O}(1) \rightarrow \text{Coker}(\varphi_4) \rightarrow \text{Coker}(\psi) \rightarrow 0, \]
which yields the resolution
\[ 0 \rightarrow 2\mathcal{O}(-1) \rightarrow 2\mathcal{O} \oplus \mathcal{O}(1) \rightarrow \text{Coker}(\varphi_4) \rightarrow 0. \]
Combining with the resolution of \( \mathcal{G} \) from above, we obtain the exact sequence
\[ 0 \rightarrow \mathcal{O}(-2) \oplus 2\mathcal{O}(-1) \rightarrow 2\mathcal{O} \oplus \mathcal{O}(1) \rightarrow \mathcal{G} \rightarrow 0. \]
By duality, this corresponds to the resolution at Proposition 4.1.3 for \( \mathcal{F} \). □

Proposition 4.2.3. There exists a geometric quotient \( W_2/G_2 \) and it is a proper open subset inside a fibre bundle over \( \mathbb{P}^2 \times \mathbb{P}^2 \) with fibre \( \mathbb{P}^{18} \).

Proof. The construction of \( W_2/G_2 \) is analogous to the construction of the geometric quotient \( W_1/G_1 \) from Proposition 2.2.2. Let \( W'_2 \subset W_2 \) be the locally closed subset given by the conditions \( \varphi_{12} = 0, \varphi_{11} \) has linearly independent entries, \( \varphi_{22} \) has linearly independent entries. The pairs of morphisms \( (\varphi_{11}, \varphi_{22}) \) form an open subset
\[ U \subset \text{Hom}(2\mathcal{O}(-3), \mathcal{O}(-2)) \times \text{Hom}(\mathcal{O}(-1), 2\mathcal{O}). \]
The reductive subgroup \( G_{2\text{red}} \) of \( G_2 \) acts on \( U \) with kernel \( \mathcal{S} \) and \( U/(G_{2\text{red}}/S) \) is isomorphic to \( \mathbb{P}^2 \times \mathbb{P}^2 \). Note that \( W'_2 \) is the trivial bundle over \( U \) with fibre \( \text{Hom}(2\mathcal{O}(-3), 2\mathcal{O}) \). The subset \( \Sigma \subset W'_2 \) given by the condition
\[ \varphi_{21} = \varphi_{22}u + v\varphi_{11}, \]
\[ u \in \text{Hom}(2\mathcal{O}(-3), \mathcal{O}(-1)), \quad v \in \text{Hom}(\mathcal{O}(-2), 2\mathcal{O}), \]
is a subbundle. The quotient bundle $Q'$ has rank 19 and descends to a vector
bundle $Q$ on $U/(G_{2\text{red}}/S)$ as at Proposition 2.2.2. Then $\mathbb{P}(Q)$ is the geometric
quotient $(W_2'/\Sigma)/G_2$.

Note that $W_2$ is the open invariant subset of injective morphism inside $W_2' \setminus \Sigma$. It is a proper subset as, for instance, the morphism represented by the matrix
\[
\begin{bmatrix}
X & Y & 0 \\
Z^3 & 0 & Y \\
0 & Z^3 & -X
\end{bmatrix}
\]
is in $W_2' \setminus \Sigma$ but is not injective. We conclude that $W_2/G_2$ exists and is a
proper open subset inside $\mathbb{P}(Q)$.

Proposition 4.2.4. The geometric quotient $W_2/G_2$ is isomorphic to $X_2$.

Proof. The canonical morphism $W_2/G_2 \to X_2$ is easily seen to be injective, there being no properly semi-stable sheaves in $X_2$, cf. Proposition 4.1.5. To show that it is an isomorphism, we must construct a resolution as in Proposition 4.1.4 starting from the Beilinson spectral sequence of a sheaf $\mathcal{F}$ in $X_2$. We prefer to work, instead, with the dual sheaf $\mathcal{G} = \mathcal{F}^* (1)$, which gives a point in $M_{\mathbb{P}^2}(5,5)$. Diagram (2.2.3) in [4] for $\mathcal{G}$ takes the form
\[
2\mathcal{O}(-2) \xrightarrow{\varphi_1} \mathcal{O}(-1) \xrightarrow{\varphi_2} \mathcal{O}(1)
\]
\[
2\mathcal{O}(-2) \xrightarrow{\varphi_3} 6\mathcal{O}(-1) \xrightarrow{\varphi_4} 5\mathcal{O}
\]
As in the proof of Proposition 3.2.4, we see that $\text{Coker}(\varphi_1)$ is the structure sheaf of a point $x \in \mathbb{P}^2$ and $\text{Ker}(\varphi_1) \simeq \mathcal{O}(-3)$. The exact sequence (2.2.5) in [4] reads
\[
0 \to \mathcal{O}(-3) \xrightarrow{\varphi_5} \text{Coker}(\varphi_4) \to \mathcal{G} \to \mathbb{C}_x \to 0.
\]
We see from this that $\text{Coker}(\varphi_4)$ has no zero-dimensional torsion. The exact sequence (2.2.4) in [4] reads
\[
0 \to 2\mathcal{O}(-2) \xrightarrow{\varphi_3} 6\mathcal{O}(-1) \xrightarrow{\varphi_4} 5\mathcal{O} \to \text{Coker}(\varphi_4) \to 0.
\]
We claim that $\varphi_3$ is equivalent to the morphism represented by the matrix
\[
\begin{bmatrix}
X & Y & Z & 0 & 0 & 0 \\
0 & 0 & 0 & X & Y & Z
\end{bmatrix}^T.
\]
Firstly, we show that any matrix representing a morphism equivalent to $\varphi_3$
has three linearly independent entries on each column. For this, we use the
fact that the only morphism from the structure sheaf of a point to $\text{Coker}(\varphi_4)$ is
the zero-morphism and we argue as in the proof that the vector space $H$ from
Proposition 2.1.4 has dimension 3. Thus, $\varphi_3$ has one of the four canonical
forms given in the proof of Proposition 3.2.5. Three of these can be eliminated
as in the proof of Proposition 3.1.3. The argument, we recall, uses the fact...
that the map $5\mathcal{O} \to \text{Coker}(\varphi_4)$ is injective on global sections as well as the
fact that the only morphism $\mathcal{O}_L(1) \to \text{Coker}(\varphi_4)$ for any line $L \subset \mathbb{P}^2$ is the
zero-morphism. Indeed, such a morphism must factor through $\varphi_5$ because
the composed morphism $\mathcal{O}_L(1) \to \text{Coker}(\varphi_4) \to G$ is zero. This follows from
the fact that both $\mathcal{O}_L(1)$ and $G$ are semi-stable and $p(\mathcal{O}_L(1)) > p(G)$.

Next, we describe $\varphi_4$. Its matrix cannot be equivalent to a matrix having
a zero-row. Indeed, if this were the case, then $\text{Coker}(\varphi_4)$ would be isomorphic
$O \oplus C$, where $C$ is a torsion sheaf with resolution

$$0 \to \mathcal{O}(-2) \to 6\mathcal{O}(-1) \to 4\mathcal{O} \to C \to 0.$$ 

We have $P_C(t) = 2t + 4$ and $C$ maps injectively to $G$ because $C \cap \mathcal{O}(-3) = \{0\}$. The semi-stability of $G$ is violated. We conclude that $\varphi_4$ has the form

$$[\xi \ 0]$$

$$[\ast \ \psi],$$

where $\xi$ is a morphism as in the proof of Proposition 4.1.6 and $\psi$ is equivalent
to the morphism $\varphi_{12}$ also from Proposition 4.1.6. We have exact sequences

$$0 \to \mathcal{O}(-2) \to 3\mathcal{O}(-1) \xrightarrow{\xi} 2\mathcal{O} \to \mathcal{O}_L(1) \to 0,$n

$$0 \to \mathcal{O}(-2) \to 3\mathcal{O}(-1) \xrightarrow{\psi} 3\mathcal{O} \to \mathcal{O}(1) \to 0.$$ 

Recall that the greatest common divisor of the maximal minors of $\xi$ is a linear form. The line $L \subset \mathbb{P}^2$ is the zero-locus of this form. From the snake lemma,
we obtain an extension

$$0 \to \mathcal{O}(1) \to \text{Coker}(\varphi_4) \to \mathcal{O}_L(1) \to 0,$n

hence a resolution

$$0 \to \mathcal{O} \to 2\mathcal{O}(1) \to \text{Coker}(\varphi_4) \to 0.$$ 

Note that $\varphi_5$ lifts to a morphism $\mathcal{O}(-3) \to 2\mathcal{O}(1)$, so we arrive at the exact sequence

$$0 \to \mathcal{O}(-3) \oplus \mathcal{O} \to 2\mathcal{O}(1) \to G \to \mathbb{C}_x \to 0.$$ 

From the horseshoe lemma, we obtain the resolution

$$0 \to \mathcal{O}(-3) \to \mathcal{O}(-3) \oplus 2\mathcal{O}(-2) \oplus \mathcal{O} \to \mathcal{O}(-1) \oplus 2\mathcal{O}(1) \to G \to 0.$$ 

The group $H^1(G)$ vanishes, hence $\mathcal{O}(-3)$ can be cancelled to yield the dual of
the resolution from Proposition 4.1.4. □

4.3. Geometric description of the strata. Let $X_0^\alpha$ denote the subset of
$X_0$ of isomorphism classes of stable sheaves. Given $\varphi \in W_0$, we denote its
domain by $\mathcal{O}(-2) \oplus 4\mathcal{O}(-2)$ and denote by $\varphi_{12}$ the restriction of $\varphi$ to the
second component. Let $Y_0$ be the open subset of $X_0$ of stable-equivalence
classes of sheaves $\mathcal{F}$ that occur as cokernels

$$0 \to \mathcal{O}(-2) \oplus 4\mathcal{O}(-2) \xrightarrow{\varphi} 5\mathcal{O}(-1) \to \mathcal{F} \to 0$$ 

in which the maximal minors of $\varphi_{12}$ have no common factor.
Proposition 4.3.1. The sheaves in $Y_0$ have the form $\mathcal{J}_Z(3)$, where $Z \subset \mathbb{P}^2$ is a zero-dimensional scheme of length 10 not contained in a cubic curve, contained in a quintic curve $C$, and $\mathcal{J}_Z \subset \mathcal{O}_C$ is its ideal sheaf.

The generic sheaves in $X^s_0$ have the form $\mathcal{O}_C(3)(-P_1 - \cdots - P_{10})$, where $C \subset \mathbb{P}^2$ is a smooth quintic curve and $P_i$, $1 \leq i \leq 10$, are distinct points on $C$ not contained in a cubic curve.

Proof. Consider the sheaf $F = \text{Coker}(\varphi)$, where the maximal minors of $\varphi_{12}$ have no common factor. According to Propositions 4.5 and 4.6 in [2], $\text{Coker}(\varphi_{12}) \simeq \mathcal{I}_Z(3)$, where $Z \subset \mathbb{P}^2$ is a zero-dimensional scheme of length 10, not contained in a cubic curve. Conversely, any $\mathcal{I}_Z(3)$ is the cokernel of some morphism $\varphi_{12} : 4\mathcal{O}(-2) \to 5\mathcal{O}(-1)$ whose maximal minors have no common factor. It now follows, as at Proposition 2.3.4(i), that $F \simeq \mathcal{J}_Z(3)$.

The claim about generic stable sheaves follows from the fact that any line bundle on a smooth curve is stable. \qed

Proposition 4.3.2. The sheaves $F$ in $X_2$ are precisely the non-split extension sheaves of the form

$$0 \longrightarrow \mathcal{J}_x(1) \longrightarrow F \longrightarrow \mathcal{C}_z \longrightarrow 0,$$

where $\mathcal{J}_x \subset \mathcal{O}_C$ is the ideal sheaf of a point $x$ on a quintic curve $C \subset \mathbb{P}^2$ and $\mathcal{C}_z$ is the structure sheaf of a point $z \in C$. When $x = z$, we exclude the possibility $F \simeq \mathcal{O}_C(1)$.

The generic sheaf in $X_2$ has the form $\mathcal{O}_C(1)(P - Q)$, where $C \subset \mathbb{P}^2$ is a smooth quintic curve and $P, Q$ are distinct points on $C$. In particular, the closure of $X_2$ contains $X_3$.

Proof. To get the extension from the claim, we apply the snake lemma to a diagram similar to the diagram from the proof of Proposition 2.3.2. Here

$$\varphi = \begin{bmatrix} u_1 & u_2 & 0 \\ * & * & v_1 \\ * & * & v_2 \end{bmatrix},$$

$C$ is given by the equation $\det(\varphi) = 0$, $x$ is the point given by the equations $v_1 = 0, v_2 = 0$ and $z$ is the point given by the equations $u_1 = 0, u_2 = 0$. To prove the converse we combine the resolutions

$$0 \longrightarrow \mathcal{O}(-4) \longrightarrow \mathcal{I}_x(1) \longrightarrow \mathcal{J}_x(1) \longrightarrow 0$$

and

$$0 \longrightarrow \mathcal{O}(-4) \longrightarrow 2\mathcal{O}(-3) \longrightarrow \mathcal{O}(-2) \longrightarrow \mathcal{C}_z \longrightarrow 0$$

into the resolution

$$0 \longrightarrow \mathcal{O}(-4) \longrightarrow \mathcal{O}(-4) \oplus 2\mathcal{O}(-3) \longrightarrow \mathcal{O}(-2) \oplus \mathcal{I}_x(1) \longrightarrow F \longrightarrow 0.$$
If $x \neq z$, then $\text{Ext}^1(C_x, \mathcal{I}_x(1)) = 0$ and the arguments from the proof of Proposition 2.3.2 show that the map $\mathcal{O}(-4) \to \mathcal{O}(-4)$ in the above complex is non-zero. Canceling $\mathcal{O}(-4)$, we get the exact sequence

$$0 \to 2\mathcal{O}(-3) \to \mathcal{O}(-2) \oplus \mathcal{I}_x(1) \to \mathcal{F} \to 0$$

from which we immediately obtain a resolution as in Proposition 4.1.4. A priori we have two possibilities: either $h^0(\mathcal{F}) = 2$ or $3$. In the first case, the map $\mathcal{O}(-4) \to \mathcal{O}(-4)$ is non-zero and we are done. In the second case, we can combine the resolutions

$$0 \to \mathcal{O}(-4) \oplus \mathcal{O}(-1) \to 2\mathcal{O} \to \mathcal{J}_x(1) \to 0$$

and

$$0 \to \mathcal{O}(-2) \to 2\mathcal{O}(-1) \to \mathcal{O} \to \mathcal{C}_z \to 0$$

into the resolution

$$0 \to \mathcal{O}(-2) \to \mathcal{O}(-4) \oplus 3\mathcal{O}(-1) \to 3\mathcal{O} \to \mathcal{F} \to 0.$$

We saw in the proof of Proposition 4.1.6 how this resolution leads to the conclusion that $\mathcal{F}$ be isomorphic to $\mathcal{O}_{C}(1)$ for a quintic curve $C \subset \mathbb{P}^2$. This possibility is excluded by hypothesis.

If $C$ is a smooth quintic curve and $P$ converges to $Q$, then $\mathcal{O}_C(1)(P - Q)$ represents a point in $X_2$ converging to the point in $X_3$ represented by $\mathcal{O}_C(1)$. This shows that $X_3 \subset X_2$. □

**Proposition 4.3.3.** \{$X_0, X_1, X_2, X_3$\} represents a stratification of $\mathbb{M}_{\mathbb{P}^2}(5, 0)$ by locally closed irreducible subvarieties of codimension 0, 1, 4, 6.

**Proof.** We saw above that $X_3$ lies in $X_2$ and we know that $X_0$ is dense in $\mathbb{M}_{\mathbb{P}^2}(5, 0)$. Thus, we only need to show that $X_2$ is included in the closure of $X_1$. For this, we shall apply the method of Theorem 3.2.3 in [4]. Consider the open subset $X = \mathbb{M}_{\mathbb{P}^2}(5, 0) \setminus X_3$ of stable-equivalence classes of sheaves satisfying the condition $H^0(\mathcal{F}(-1)) = 0$. Using the Beilinson monad for $\mathcal{F}(-1)$, we see that $X$ is parametrised by an open subset $M$ inside the space of monads of the form

$$0 \to 10\mathcal{O}(-1) \xrightarrow{\phi} 15\mathcal{O} \xrightarrow{B} 5\mathcal{O}(1) \to 0.$$

The automorphism of $\mathbb{M}_{\mathbb{P}^2}(5, 0)$ taking the stable-equivalence class of a sheaf $\mathcal{F}$ to the stable-equivalence class of the dual sheaf $\mathcal{F}^D$ leaves $X$ invariant. Thus, in view of Serre duality, he have $H^1(\mathcal{F}(1)) = H^0(\mathcal{F}^D(-1)) = 0$ for all $\mathcal{F}$ in $X$. This allows us to deduce that the map $\Phi$ defined by $\Phi(A, B) = B$ has surjective differential at every point in $M$. As at Theorem 3.2.3 in [4], this leads to the conclusion that $X_2$ is included in the closure of $X_1$ in $X$, hence $X_2$ is included in the closure of $X_1$ in $\mathbb{M}_{\mathbb{P}^2}(5, 0)$. □
