Abstract: (1) Background. Snake venom phosphodiesterases (SVPDEs) are among the least studied venom enzymes. In envenomation, they display various pathological effects, including induction of hypotension, inhibition of platelet aggregation, edema, and paralysis. Until now, there have been no 3D structural studies of these enzymes, thereby preventing structure–function analysis. To enable such investigations, the present work describes the model-based structural and functional characterization of a phosphodiesterase from Crotalus adamanteus venom, named PDE_Ca. (2) Methods. The PDE_Ca structure model was produced and validated using various software (model building: I-TESSER, MODELLER 9v19, Swiss-Model, and validation tools: PROCHECK, ERRAT, Molecular Dynamic Simulation, and Verif3D). (3) Results. The proposed model of the enzyme indicates that the 3D structure of PDE_Ca comprises four domains, a somatomedin B domain, a somatomedin B-like domain, an ectonucleotide pyrophosphatase domain, and a DNA/RNA non-specific domain. Sequence and structural analyses suggest that differences in length and composition among homologous snake venom sequences may account for their differences in substrate specificity. Other properties that may influence substrate specificity are the average volume and depth of the active site cavity. (4) Conclusion. Sequence comparisons indicate that SVPDEs exhibit high sequence identity but comparatively low identity with mammalian and bacterial PDEs.

Keywords: snake venom; phosphodiesterases; amino acid sequence and three-dimensional structural analysis; variable substrate specificity; PDE_Ca structure–function relationship

Key Contribution: This is the first report on snake venom phosphodiesterase (SVPDE) that describes the overall structural properties, makes structural comparisons, and examines the structural basis of substrate specificity.

1. Introduction

Snake venom is a crude mixture that contains enzymatic and non-enzymatic proteins, peptides, organic compounds of low molecular weight, and inorganic compounds [1,2]. Proteins constitute the major portion (about 90%) of the total dry mass of crude snake venom, with or without catalytic activity, including neurotoxins, cardiotoxins, C-type lectins, proteinases, metalloproteinases, serine proteinases, phospholipases, hyaluronidases, acetylcholinesterases, L-amino acid oxidases, three-finger toxins, phospholipase A2s, and nucleases [3–9]. Metalloproteinases, serine proteinases, phospholipases, and neurotoxins are the most widely studied snake venom proteins, as they occur in high concentrations and
are relatively easy to purify [1-5,10-12]. Other enzymes, such as nucleases, exist in small quantities and are the least studied. Nucleases are capable of cleaving phosphodiester bonds in nucleic acids, and, in snake venom, they have been classified as endonucleases and exonucleases [13,14]. Phosphodiesterases are generally considered exonucleases [14].

Phosphodiesterases (E.C. No. 3.1.4.1) belong to the Ectonucleotide pyrophosphatase/phosphodiesterase (E-NPP) family of metalloenzymes [13]. Generally, viperid venoms contain more phosphodiesterases (PDEs) than crotalid or elapid venoms [15,16]. Phosphodiesterases cleave phosphodiester bonds in polynucleotides in a sequential manner, starting at the 3′-end, and release 5′-mononucleotides [16]. PDEs have been shown to hydrolyze a wide variety of nucleotides, such as ATP, ADP, NAD+, NADP+, and GDP [4,17]. Because this enzyme degrades oligonucleotide fragments, there is increasing demand for purified PDE for use in the structural analysis of nucleic acids [17,18].

PDEs have been isolated from various snake venoms, including Deinagkistrodon acutus [19], Bothrops atrox [20], Bothrops alternatus [21], Cerastes vipera [22], Crotalus atrox [23], Crotalus adamanteus [24,25], Crotalus durissus terrificus [25], Protobothrops flavoviridis [26], and Vipera aspis [27]. In addition to snake venoms, they also occur in spider venoms [28]. The structures of human, mouse, and bacterial PDEs have been well studied compared to snake and spider venom PDEs.

Snake venom PDE was first reported by Uzawa [29]. This is one of the least studied enzymes in snake venom due to the fact that earlier reports showed it to be non-toxic and involved only in digestion [13]. However, recent reports indicate that PDE has a major role in envenomation by hydrolyzing DNA and RNA, releasing adenosine and other purine nucleosides [30,31]. Adenosine induces a variety of pathological and pharmacological effects, such as increased vascular permeability, hypotension, inhibition of platelet aggregation, edema, and paralysis [32,33]. Snake venom phosphodiesterases (SVPDEs) have also been used as therapeutic agents in various diseases and conditions, such as cerebrovascular and cardiovascular diseases, hypertension, and atherosclerosis [34].

SVPDEs are monomeric proteins of high molecular weight (98–140 kDa), with basic pIs (8.4–9.2), and metal cofactors, usually zinc, which are essential for catalytic activity [35–38]. Some studies report a dimeric structure [13,39,40]. Sometimes, a single venom may contain multiple PDE isoforms [13,37,40]. Although the amino acid sequences of PDEs from various snake species are available in the literature, there is no information regarding their three-dimensional (3D) structures. Therefore, it is difficult to correlate function with structure. In order to enable structure-function studies, here we present a model-based 3D structural characterization of the phosphodiesterase from Crotalus adamanteus venom. The PDE_Ca structure model was produced and validated using various software (I-TESSER, MODELLER 9v19, Swiss-Model, PROCHECK, ERRAT, and Veri3D). The sequence alignment, structure-based substrate specificity, maturation, and comparison with PDEs from other organisms are also discussed.

2. Results and Discussion

2.1. Sequence Alignment Analysis

The PDE_Ca precursor contains 851 amino acids with 830 amino acid residues in the mature form. Sequence alignment indicates high sequence identity among SVPDEs and comparatively low sequence identity (<65%) with their mammalian counterparts (Table 1). The average sequence identities among SVPDEs and mammalian phosphodiesterases are 90.6% and 58.3%, respectively. The metal ion-binding/active site residues (Zn^{2+} 1 (D153, T191, D358, H359), Zn^{2+} 2 (D311, H315, and H476), and Ca^{2+} (N751, D753, H755, D757) (PDE_Ca precursor numbering scheme) are fully conserved among all phosphodiesterases examined, except N751 and H755 in SVPDEs, where these have mutated to D751 and R755, respectively, in mammalian homologs (Figure 1). Amino acid residues around the metal ion binding and active sites are highly conserved among all phosphodiesterases examined. The amino acid sequence of PDE_Ca contains 33 cysteine residues, of which 32 form 16 disulfide bridges (Table 2).
The generated model and DiANNA web server [38] also confirmed the presence of sixteen disulfide bridges in PDE_Ca.
Figure 1. Cont.
Figure 1. Sequence alignment of snake venom phosphodiesterases (SVPDEs) and mammalian homologs. 5IJQ; crystal of human Autotaxin (ENPP2); 4B56: Ectonucleotide pyrophosphatase phosphodiesterase-1 (NPP1) (Mus musculus); 6CO1: human Ectonucleotide pyrophosphatase/phosphodiesterase 3 (ENPP3); 5GZ4, phosphodiesterase Naja atra atra (Gene Bank ID: A0A2D0TC04), PDE_Na, phosphodiesterase Macrovipera lebetina (Vl) (Gene Bank ID: AHJ80885.1), PDE_Mi, phosphodiesterase Macrospora lebetina (Vl) (Gene Bank ID: BAN89426.1), PDE_Ca, phosphodiesterase Crotalus adamanteus (Gene Bank ID: JAS04699.1),
PDE\textsubscript{Pm}, phosphodiesterase Protobothrops mucrosquamatus (Gene Bank ID: XP_015675293.1), PDE\textsubscript{Pe}, phosphodiesterase Protobothrops elegans (Gene Bank ID: BAP39928.1). Residues involved in catalysis and metal ion binding are underlined with blue and black, respectively. Cysteine residues that form disulfide bridges are linked (yellow lines). Putatively N-glycosylated amino acid residues are underlined in brown. Amino acid residues in the somatomedin B domain, the somatomedin B-like domain, the ectonucleotide pyrophosphatase/phosphodiesterase domain (also called autotaxin), and the DNA/RNA non-specific domain, are colored green, light green, blue, and red, respectively. Secondary structural elements (alpha helices and beta strands) are shown above the sequence. Sequence numbering corresponds to the PDE\textsubscript{Ca} precursor protein.

2.2. Domain Analysis

The primary structure of mature PDE_Ca contains four domains—the somatomedin B domain (residues 33–79), somatomedin B-like domain (residues 81–124), ectonucleotide pyrophosphatase/phosphodiesterase domain (also called autotaxin) (residues 147–479), and the DNA/RNA non-specific domain (residues 534–867) (Figure 1). The regions of amino acid residues from 124–146, 480–533, and 868–877 are connecting segments.

The ThreaDom (Threading-based Protein Domain Prediction) online web server [41] for domain conservation indicated that the domain architecture of PDE_Ca is fully conserved, with other proteins in the Protein Data Bank (PDB) containing a similar structure fold (Figure 2). The molecular weights of PDE_Ca in zymogen and the mature forms were 96.37 and 93.10 kDa, with corresponding pls of 8.13 and 8.05, respectively [42]. The theoretically calculated molecular weights and pls accord with the experimentally measured values for other SVPDEs [43–47].

![Domain Conservation Score of PDE_Ca Model](image)

**Figure 2.** The ThreaDom-based domain prediction in the domain conservation score profile. Four domains are separated by three connecting segments. Vertical dotted lines indicate the start and end locations of each putative connecting segment. Vertical solid lines denote predicted boundaries at the middle of the connecting segments.

2.3. Glycosylation Sites

The primary structure of PDE_Ca contains 60 asparagine (N) residues (ProtParam, [48]), of which nine were identified as potential glycosylation sites using the NetNGlyc 1.0 Server (N39, N222, N265, N276, N412, N526, N613, N695, and N771) (Figure 1). These asparagine residues are fully conserved among SVPDEs (Figure 1). Glycosylation sites were also confirmed with the ScanProsite tool [49]. The primary structure of Vipera lebetina has also been shown to contain nine putative N-glycosylation sites [43]. PDEs of B. jararaca and Walterinnesia aegyptia contain 33% and 24% carbohydrates, respectively [48,49].

2.4. Homology Modeling and Model Evaluation

The homology model for three-dimensional (3D) structure characterization was produced using various online modeling servers [I-TESSER [50], MODELLER 9v19 program [51], and SWISS Model [52], using atomic coordinates of human ectonucleotide pyrophosphatase/phosphodiesterase 3 (PDB ID:
6C01, amino acid sequence identity 63.39%) as a template [53]. The best model was chosen based on analyses using the PROCHECK, ERRAT, and Veri3D software [54–57].

The PROCHECK analysis of the best model shows that >95% of the amino acid residues are in the most favored region of the graph (Figure 3). The remaining 5% are in the allowed region with no residues in the forbidden/disallowed region. ERRAT analysis shows an overall quality factor of 87.88 for the PDE_Ca model, which lies in the average quality range for 3D protein structures [55].

Figure 3. A Ramachandran plot of the modeled structure of PDE_Ca. In total, >95% of the amino acid residues are in the most favored region, while the remaining 5% are in the allowed region with no residues in the forbidden/disallowed region. Quadrant I displays a region where multiple conformations are allowed. Quadrant II shows the biggest region in the graph, with the most favorable conformations of atoms. Quadrant III shows the next biggest region in the graph, where the right-handed alpha helices lie. Quadrant IV has almost no outlined region. This conformation is disfavored due to steric clash.
2.5. Molecular Dynamics Simulation

GROMACS, AMBER16, MDWeb, and MDMobby [58–60] all produced the same results. MD simulation analysis indicated that all structural parameters, such as chirality, disulfide bonds, and the absence of steric clashes, were correct (Figure S1A). The two basic assessments (root mean square deviation (RMSD) and radius of gyration (RG)) used to validate the structures through MD simulation were analyzed. The RMSD deviation indicated that the PDE_Ca structure did not deviate more than 1 Å from the initial structure, and the RG was also maintained at around 31.7 Å (Figure S1B,C). Flexibility analysis (Bfactor and RMSD per residue), identified some flexible regions, located mostly in loop regions (Figure S1C,D). All these analyses indicate that the simulated structure does not exhibit critical structural deformations.

2.6. Overall Structure of PDE_Ca

The 3D structure of PDE_Ca is similar to that of the other members of the alkaline phosphatase-like superfamily (ALP-like superfamily) [25,61–63]. PDE_Ca has a complex structure. It is a multi-domain protein that consists of four domains—a somatomedin B domain, a somatomedin B-like domain, an ectonucleotide pyrophosphatase/phosphodiesterase domain (also called autotaxin), and a DNA/RNA non-specific domain (Figure 4). These domains are briefly described below.

![Figure 4. Overall structure of PDE_Ca. (A) cartoon representation. The active site and metal ion-binding residues are shown as green sticks. Zn^{2+} and Ca^{2+} ions are shown as gray and green spheres, respectively. Disulfide bridges are represented by yellow sticks. (B–D), residues involved in Zn^{2+} ion-binding, catalysis, and Ca^{2+} ion-binding are highlighted. Parts of the secondary structure belonging to the somatomedin B domain, somatomedin B-like domain, ectonucleotide pyrophosphatase/phosphodiesterase domain, DNA/RNA non-specific domain, and connecting are colored in green, light green, blue, red, and black, respectively.](image-url)

2.6.1. Somatomedin B Domain

The somatomedin B domain (SMB) is located at the N-terminus of the protein and comprises amino acid residues 33–79 (Figures 1, 4 and 5). It has two alpha helices (Figures 4 and 5). The SMB domain is stabilized by four intrachain disulfide bridges, one salt bridge (between Asp52-Arg58) (Table 3), and extensive hydrogen bonding (14 intrachain H-bonds).

2.6.2. Somatomedin B-like Domain

The somatomedin B domain connects to another domain called the Somatomedin B-like domain (SMB-like). This domain consists of residues 81 to 124 (Figure 1). Like the somatomedin B domain, it
also contains eight cysteine residues in four disulfide bridges (Figure 1). The secondary structure of this domain contains two alpha helices (Figures 4 and 5). Beside its disulfides, the SMB-like domain is stabilized by four salt bridges (Arg82-Glu85, Arg87-Asp104, Arg87-Asp98, Lys102-Asp98), and thirteen interchain H-bonds (four with the SMB domain and nine with the PDE domain), as well as 24 intrachain H-bonds.

Both the SMB and SMB-like domains are highly compact. Disulfide bridges are arranged in the centers of both domains, forming covalently bonded cores (Figure 4).

2.6.3. Ectonucleotide Pyrophosphatase/Phosphodiesterase Domain

The SMB-like domain connects to the catalytic domain, called the ectonucleotide pyrophosphatase/phosphodiesterase (ENPP/PDE) domain, through a short connecting segment of 22 amino acid residues (125–146) (Figure 1, 4 and 5).

The ENPP/PDE domain consists of amino acid residues 147–479 (Figure 1). It contains five cysteine residues, two of which make an intrachain disulfide bridge and three of which make interchain disulfide bridges (two with the connecting segment and one with the DNA/RNA non-specific domain) (Figures 1 and 4) (Table 2). This domain also contains the active site residues, together with the two zinc ions (Figure 4). One of the zinc ions (Zn$^{2+}$1) is coordinated by four amino acids (Asp153, Thr191, Asp358, and His59), and the other one (Zn$^{2+}$2) is coordinated by three residues (Asp311, His315, and His476). All these catalytic amino acid residues are fully conserved in mouse NPP1 [62], human NPP3 (61), human autotaxin ENPP2 [64], and bacterial PDE [29] (Figure 6).

The secondary structure of this domain contains 14 beta strands and 14 alpha helices (Figure 5). Of the fourteen alpha helices and beta strands, seven and five are short alpha helices and beta strands, respectively. This domain is stabilized by interchain disulfide bridges (one with the SMB-like domain and seven with the DNA/RNA non-specific domain), 13 salt bridges (Table 3), and numerous interchain H-bonds.

2.6.4. DNA/RNA Non-Specific Domain

This domain comprises residues 603 to 867 (Figure 1). It contains nine cysteines that form one intrachain and three interchain disulfides (one with the PDE domain and two with the connecting segment) (Figure 4). This domain also contains the Ca$^{2+}$-binding loop (Figure 4). The secondary structure of this domain contains seven beta strands and ten alpha helices (Figures 4 and 5). This domain is connected to the PDE domains through a long loop, called the lasso loop [65]. This domain is stabilized by four disulfides, eight salt bridges, and numerous H-bonds.
Figure 5. Topology diagram of PDE-Ca. The alpha helices (1–20) and beta strands (A–L) are represented as cylinders and arrows, respectively. Short alpha helices and beta strands are shown as primes (e.g., 17'). Secondary structures and amino acid residues in alpha helices and beta strands were assigned from the primary sequence using the program DSSP [66] and were confirmed with PyMOL from the tertiary structure. Parts of the secondary structure belonging to the somatomedin B, somatomedin B-like, ectonucleotide pyrophosphatase/phosphodiesterase, and DNA/RNA non-specific domains, as well as the connecting segments (UN), are colored in green, light green, blue, red, and black, respectively.
Figure 6. Active site comparison of (A) PDE_Ca with (B) human Ectonucleotide pyrophosphatase/phosphodiesterase 3 (ENPP3), (C) Ectonucleotide pyrophosphatase-phosphodiesterase-1 (NPP1) (Mus musculus), (D) ENPP2 (human Autotaxin), (E) Xac Nucleotide Pyrophosphatase/Phosphodiesterase (Xanthomonas axonopodis), and (F) Phosphodiesterase Naja atra. Metal ion-binding amino acid residues are displayed as sticks and metal ions as grey spheres.

2.6.5. Metal Ion-Binding Sites

SVPDEs are metalloenzymes that contain zinc and calcium ions [6,26,35,36,67]. The zinc ion participates in the active site and is important for catalytic activity [26,35–67]. In the modeled structure of PDE_Ca, two zinc ions and one calcium ion were found (Figure 4). Of the two zinc ions, one (Zn$^{2+}$1) is coordinated by amino acid residues Asp153, Thr191, His359, and Asp358 (Figure 4), and the other (Zn$^{2+}$2) is coordinated by amino acid residues Asp311, His315, and His476 (Figure 4). The Ca$^{2+}$ is coordinated by amino acid residues Asn751, Asp753, His755, and Asp757 (Figure 4). The metal ion comparison with the human Ectonucleotide pyrophosphatase/phosphodiesterase 3, Ectonucleotide pyrophosphatase-phosphodiesterase-1 (Mus musculus), ENPP2 (Human Autotaxin), Xac Nucleotide Pyrophosphatase/Phosphodiesterase (Xanthomonas axonopodis), and Taiwan cobra (Naja atra atra) PDE (PDB ID: 5GZ4 and 5GZ5) shows that the amino acid residues coordinating these metal ions are fully conserved (Figures 1A–F and 6A–F).
2.7. Structural Basis for Substrate Specificity of Snake Venom Phosphodiesterases

For substrates other than oligonucleotides, SVPDEs display variable substrate specificity [43–47]. Among the SVPDEs for which substrate specificity has been studied, the PDEs from *Vipera lebetina* and *Daboia russelli russelli* hydrolyze ADP [43], while PDEs from *Crotalus adamanteus*, *Trimeresurus stejnegeri* and *Bothrops jararaca* hydrolyze ATP [45–47].

To explain these broad specificities of SVPDEs, the structures of two other PDEs from *Vipera lebetina* (PDE _Vl_) and *Bothrops atrox* (PDE _Ba_) were modeled, using the same modeling and validation programs used for the PDE _Ca_ structural model. The atomic coordinate of human Ectonucleotide pyrophosphatase/phosphodiesterase 3 (PDB ID: 6C01, amino acid sequence identity 64.09% and 62.91% with PDE _Vl_ and PDE _Ba_, respectively) was used as a template. The Ramachandran plot analysis indicates that in both the modeled structures, 98% of amino acid residues were in the favored region of the plot, and 2% were in the allowed region (Figures S2 and S3). The ERRAT analysis shows an overall quality factor of 90 for the modeled structure, which lies in the average quality range for the protein 3D structures (Figures S4 and S5) [55]. The modeled structures of the PDE _Ca_, PDE of *Vipera lebetina* (PDE _Vl_), and *Bothrops atrox* (PDE _Ba_) were compared, taking into account the active site residue composition, active site cavity volume and average depth, and the surface charge distribution (Figure 7, Table 4). The active site’s amino acid residues are the same for these enzymes. However, the average active site’s cavity volume, the average depth of the active site, and the surface charge distribution vary considerably (Figure 7, Table 4).

The average active site cavity volumes of PDE _Ca_, PDE _Vl_, and PDE _Ba_ are 6608.25, 3985.03, and 2243.11 Å³, respectively, with corresponding average depths of 21.39, 12.54, and 9.86 Å, respectively (Table 4). These values indicate that the average active site cavity volume and depth of PDE _Ca_ is much larger than that of either PDE _Vl_ or PDE _Ba_. These characteristics permit larger substrates (ATP) to access the active site of PDE _Ca_, while preventing it for PDE _Vl_.

Another factor that affects the substrate specificity of these enzymes is the surface charge distribution (Figure 7). The surface charge of PDE _Ca_ (overall and around the active site) is highly positive (Figure 7A), for PDE _Vl_ it is partially positive and negative (Figure 7B). Analysis of the active site cavity volume and its average depth indicate that SVPDEs with small active site cavity volumes and average depths (like *Vipera lebetina*, *Daboia russelli russelli*, and *Cerastes cerastes*) (Table 4) show a high preference for ADP, while other SVPDEs with large active site volumes and average depths (like PDEs from *Crotalus adamanteus*, *Trimeresurus stejnegeri*, and *Bothrops jararaca*) show a high preference for ATP.

### Table 4. Average active site cavity volumes and average active site cavity depths of SVPDEs and their mammalian and bacterial counterparts.

| Protein      | Average Volume (Å³) | Average Depth (Å) |
|--------------|---------------------|-------------------|
| PD _Ca_ model | 6608.25             | 21.39             |
| PD _Vl_ model | 3985.03             | 12.54             |
| 6C01         | 14,690.95           | 19.13             |
| 4B56         | 3651.33             | 16.30             |
| 2GSN         | 10,107.28           | 18.58             |
| 4ZG7         | 11,367.42           | 17.94             |
2.8. Structural Alignment between PDE_Ca, Human ENPP3, Mouse NPP1, Human Autotaxin, Xa NPP1, PDE_Vl, PDE_Ba and Naja atra atra PDE.

The structural alignment between PDE_Ca, human ENPP3 [53], mouse NPP1 [61], human autotaxin [63], Xa NPP1 [62], phosphodiesterase from Vipera lebetina (PDE_Vl), Bothrops atrox (PDE_Ba), and the PDE from Taiwan cobra (Naja atra atra; PDB ID: 5GZ4 and 5GZ5) shows that the three-dimensional structural folds of these enzymes are similar and that all of them align well, with an RMSD value range between 0.21 and 0.92 (average RMSD value of 0.61) (Table 5) (Figure 8). They have the same active site residues (Figures 1 and 6) and disulfide bridges (Figure 1). However, the amino acid residues in the loop regions vary considerably, both in composition and length (Figure 8). For this reason, the surface charge distribution also varies (Figure 7A–G), which may impart variable substrate specificity to these enzymes [45,68,69]. The overall surface charge for the SVPDEs is positive, while it is negative for human ENPP3, mouse NPP1, human autotaxin, and Xa NPP1 (Figure 7C–F). The average active site cavity volume and average depth also vary among these enzymes (Table 4).

The phylogenetic tree analysis indicates that PDE_Ca has a close evolutionary relationship with SVPDEs and PDEs from human beings and mice (Figure S6).
Figure 8. Structural alignment among SVPDEs (PDE$_{Ca}$, PDE$_{Vl}$, and PDE$_{Ba}$) and their mammalian and bacterial counterparts; (A) PDE$_{Ca}$ (green) align human Ectonucleotide pyrophosphatase/phosphodiesterase 3 (ENPP3) (Cyan), (B) PDE$_{Ca}$ (green) align Ectonucleotide pyrophosphatase-

phosphodiesterase-1 (NPP1) (*Mus musculus*) (yellow), (C) PDE_Ca (green) align ENPP2 (human Autotaxin) (red), (D) PDE_Ca (green) align Xac Nucleotide Pyrophosphatase/Phosphodiesterase (*Xanthomonas axonopodis*) (magenta), (E) PDE_Ca (green) align *Vipera lebetina* phosphodiesterase (blue), (F) PDE_Ca (green) align *Bothrops atrox* phosphodiesterase (orange), (G) PDE_Ca (green) align 5ZG4 (light pink). Loops exhibiting differences and their corresponding amino acid residues are shown in boxes and colored in blue, red, magenta, orange, yellow, and cyan for PDE_Ca, ENPP3, NPP1, PDE_Vl, PDE_Ba, and 5GZ4, respectively.

Table 5. Root mean square deviation values of PDE_Ca, PDE_Vl, PDE_Ba, and their mammalian counterparts.

| Protein             | RMSD Value |
|---------------------|------------|
| PDE_Ca aligned 6C01 | 0.21       |
| PDE_Ca aligned 4BS6 | 0.72       |
| PDE_Ca aligned 4ZG7 | 0.73       |
| PDE_Ca aligned 2GSN | 0.92       |
| PDE_Ca aligned PDE_Vl | 0.57    |
| PDE_Ca aligned PDE_Ba | 0.56    |
| PDE_Ca aligned 5GZ4 | 0.60       |

2.9. Maturation Mechanism for SVPDEs

PDE_Ca, like other SVPDEs, is synthesized as a precursor protein (zymogen) [43,45]. The immature PDE_Ca contains 851 amino acid residues [64] (Figure 1), in which the first 23 amino acid residues belong to a signal peptide (confirmed with SignalP 3.0 [70], Figure 9A), eight amino acid residues to the activation peptide, and the remaining 820 amino acid residues to the mature protein [48]. The signal peptide prevents the protein from proper folding and is removed cotranslationally or by signal peptidases [71,72]. The Kyte and Doolittle hydropathy plot [42] indicates that this region is located in the hydrophilic part (Figure 9B). The function of the activation peptide is unknown. However, this is considered important for proper folding of the protein, as described for spider venom and plant proteins [2,73]. This part is removed by endopeptidases [74] (Figure 9D). It is also located in the hydrophilic region of the Kyte and Doolittle hydropathy plot [42], and it is exposed on the surface of the protein (and thereby accessible to peptidases). The remaining peptide does not undergo further processing.
3. Materials and Methods

3.1. Sequence Retrieval and Multiple Sequence Alignment

The amino acid sequence of PDE_Ca (851 amino acid residues) (gene bank accession no. JAS04699.1; UniProt ID: A0A0F7Z2Q3) [64] was obtained from the NCBI (National Centre for Biotechnology Information) protein database (http://www.ncbi.nlm.nih.gov/protein). The signal peptide was identified using the SignalP 3.0 server [70] with default parameters. The amino acid sequence of PD_Ca was used as a query for searching homologous proteins from the non-redundant database by searching with the NCBI Protein BLAST using default parameters. The multiple sequence alignment of the selected homologous protein sequences, including the amino acid sequence of PD_Ca, was generated using MUSCLE [75]. The aligned sequences were edited and colored in Box-shade V3.21 [76].

3.2. Sequence Logo Generated from Multiple Sequence Alignment

The Weblogo 3.2 [77,78] was used to illustrate the conservation patterns of amino acids in the protein sequence, and graphically represent the multiple sequence alignment, using default parameters, except for the composition, which was done without adjustment.
3.3. In Silico Analysis of the Domain and Biochemical Properties of the PDE_Ca

The PDE_Ca primary sequence was analyzed for the presence of domains/motifs using the conserved domain search tool [79], available at http://www.ncbi.nlm.nih.gov/Structure/cdd/wrpsb.cgi. The protparam and Compute pI/MW tools from the ExPASy Proteomics server (http://web.expasy.org/compute_pI/) [42] were used to compute the isoelectric point (pI) and molecular weight of the protein.

3.4. Prediction of Ligand Binding and Glycosylation Sites

The 3DLigandSite-Ligand binding site prediction Server [80] was used for ligand binding amino acid residues in PDE_Ca, while putative glycosylation sites were predicted using the NetNGlyc 1.0 Server [48] and ScanProsite tool [81], with default parameters.

3.5. Disulfide Bond Prediction

The DiANNA web server [38] and Dinosolve [82–86] were used for prediction of disulfide bridges in PDE_Ca.

3.6. Homology Model Building of PDE_Ca

The 3D model of PDE_Ca was generated using various online proteins modeling programs, such as I-TESSER [87], the MODELLER 9v19 program [51], and SWISS Model [52], using the atomic coordinates of human Ectonucleotide pyrophosphatase/phosphodiesterase 3 (PDB ID: 6C01, amino acid sequence identity 63.39%) as a template [53]. The final model was selected based on the quality and validation reports generated by PROCHECK [50].

3.7. Molecular Dynamics Simulation

The modeled structure of PDE_Ca was validated through MD simulation using various programs, like AMBER16 [58], GROMACS [59], MDweb, and MDMoby [60]. The all-atom protein interaction was determined using the FF14SB force field [85]. The web-server H++ [84] was used to determine the protonation states of the amino acid side chain at pH 7.0. Chloride ions were used for system neutralization and were placed in a rectangular box of TIP3P water and extended to at least 15 Å from any protein atom. For the removal of bad contacts from the structure, the system was energy minimized for 500 conjugate gradients steps by applying a constant force constraint of 15 kcal/mol. Å². The system was then heated gradually from 0 to 300 K for 250 ps with a constant atom number, volume, and temperature (NVT) ensemble, at the same time that the protein was restrained with a constant force of 10 kcal/mol. Å². The equilibration step was carried out using the constant atom number, pressure, and temperature (NPT) ensemble for 500 ps, and the simulation was done for 100 ns with a 4 fs time step. The temperature and pressure were kept constant at 300 K and 1 atm, respectively, by Langevin coupling. The long-range electrostatic interactions were computed with the Particle–Mesh Ewald method (PME) [85], keeping the cut-off distance of 10 Å to Van der Waals interactions.

3.8. Model Validation

The build model of PDE_Ca was validated using the PROCHECK software [50,54], ERRAT version 2.0 [55], and Verify 3D [56,57].

3.9. Structure Superimposition

The build PDE_Ca protein model was aligned to homologous proteins using the PyMOL molecular graphics visualization program [86].
3.10. Surface Charge Analysis

Charge and radius calculations were carried out using the PDB2PQR server program [88]. The surface and charge were then visualized in ABPS Tools from the PyMOL molecular graphics visualization program [86].

4. Conclusions

In conclusion, a sequence and structural analysis of PDE_Ca was carried out using various computational biology programs. The amino acid sequence comparison analysis indicated that SVPDEs display high sequence identity (90.6%) with one another and comparatively low sequence identity (58.33%) with mammalian and bacterial PDEs. The three-dimensional model of PDE_Ca, produced using various modeling programs, was of good quality, as shown by the PROCHECK and ERRAT analysis. The modeled structure was further analyzed by molecular dynamic simulation, and the analysis indicated that all important structural parameters, such as chirality, disulfide bonds, and the absence of steric clashes, were correct. The root mean square deviation and radius of the gyration did not suffer significantly during model building and were maintained at 1 Å and 31.7 Å, respectively. The structural analysis indicated that the complex structure of PDE_Ca is folded into a multi-domain protein that comprises four domains—a somatomedin B domain, a somatomedin B-like domain, an Ectonucleotide pyrophosphatase/Phosphodiesterase domain (also called autotaxin), and a DNA/RNA non-specific domain. Structural comparisons with PDEs from other snake venoms, and mammalian and bacterial counterparts indicated that the surface charge distribution and the average active site cavity volume and depth vary considerably, which may contribute to their variable substrate specificity. Finally, during the maturation process, venom PDEs lose their signal and activation peptides to convert into the fully active mature forms. The structure of PDE_Ca presented in this paper is only a predicted structure. These conclusions need to be confirmed with experimental evidence [89].
