Abstract

In this note a one-dimensional band model is proposed based on a periodic Dirac comb having an identical mass distribution \( m(x) \). in each unit cell. The mass function is represented as a Hermitian, non-local separable operator. Two specific cases—a constant mass model and a sinusoidal mass model—are examined. The lowest electron and positron bands for the constant mass case are similar to those for the standard relativistic Kronig-Penney model, suggesting that non-locality has little influence. The results for the sinusoidal case are consistent with the expectation that at low wavenumber an electron “feels” it has an average constant mass, but at high wave number, the particle “sees” the periodic mass variation and the band is distorted.

Keywords: Relativistic Dirac comb, Kronig-Penney model, energy band structure, position-dependent mass.

Introduction

The desire for considering spatially dependent electron masses in solid state systems was expressed as long ago as the early 1940’s[1] and was made explicit through the work of Wannier, Slater, Luttinger and Kohn [2] with the development of effective mass theory in the early post-war years. Gora and Williams[3] were, it seems, the first to adapt the kinetic energy operator to this situation, but after noting that their original expression was not Hermitian, they proposed the non-relativistic kinetic energy operator

\[ K = -\frac{1}{4\hbar^2} [m(\vec{r})^{-1/2}\nabla + \nabla m(\vec{r})^{-1/2}] \] (1)

which was then derived by others from various physical perspectives[4]. O. Von Roos[4] subsequently pointed out that (1) was not unique, being just a special case of

\[ K = -\frac{\hbar^2}{4} [m^a \nabla m^b \nabla m^c + m^c \nabla m^b \nabla m^a], \quad a + b + c = -1, \] (2)

On the basis of Bargmann’s theorem[5] he also argued that (2) was unphysical and proved explicitly that the ambiguity was related to a lack of Galilean invariance, i.e. observers in different inertial frames would measure different results for physical properties of such a system. Thus, Von Roos maintained that the very concept of position dependent mass should be avoided as was possible by returning to more fundamental principles. Nevertheless the position dependent mass (PDM) concept has been popular and (2) (usually with \( c = a \)) has been the basis of a plethora of calculations over the last 30 years. A representative set of papers where PDM is applied to various simple quantum systems is given in[6-12].

In the relativistic case, though Bargmann’s theorem, that physical wave packets cannot be constructed from components corresponding to different masses, still cannot be avoided, at least it can be argued that non-uniqueness is less of a problem since the mass in the Dirac equation occurs simply as a linear operator, similar to the potential[13-15]. The aim here is to take advantage of this by introducing a class of exactly solvable relativistic Kronig-Penney models (i.e. where the lattice potential is a periodic Dirac comb with amplitude \( v_0 \)) relative to a fixed frame where the mass is replaced by the non-local separable linear operator

\[ m(x)\psi(x) = m_0 \sum_{l=-N}^N \mu(x - la) \int_{-\infty}^{\infty} dx' \mu(x' - la)\psi(x'), \] (3)

( \( a \) is the lattice spacing, \( N \to \infty \) the number of unit cells). As will be seen, to construct a particular model one need only specify the Fourier coefficients of \( \mu(x) \), the mass profile in a unit cell. This note examines the case

\[ \mu(x) = \frac{1}{2} [(1 + b) + (1 - b) \cos(2\pi x/a)], \quad (0 < b < 1) \] (4)
Figure 1: Unit cell mass profile for $b = .1$, $a = 5$.

illustrated in Fig.1 for $b = .1$

The Fourier coefficients for (4) are

$$\hat{\mu}_n = 2\frac{\pi^2(b + 1) - a^2 b k_n^2}{k_n (4\pi^2 - a^2 k_n^2)} \sin(k_n a/2)$$

(5)

$$k_n = k + K_n$$

and $K_n = 2\pi n/a$ is the $n$-th reciprocal lattice vector. The constant mass case corresponds to $b = 1$.

We present the details of the calculation in the next section, followed by the numerical examination of the specific case (4); the results are discussed in the concluding section.

**Calculation**

The one-dimensional Dirac equation can be written

$$i\hbar c \phi_1' = [E - m(x)c^2 - V(x)]\phi_2(x)$$  \hspace{1cm} (4a)

$$i\hbar c \phi_2' = [E + m(x)c^2 - V(x)]\phi_1(x)$$  \hspace{1cm} (4b)

and after inserting the Bloch form of the wave function components,

$$\phi_j(x) = \sum_n C_n^j e^{ik_n x},$$

(5)

where $k$ is the crystal momentum (for simplicity we write $k_n = k + K_n$) one has

$$\sum_n [\hbar c k_n C_n^1 + EC_n^2] e^{ik_n x} = \sum_{l,n} C_n^1 e^{ik_n la} \{v_0 \delta(x - la) + u_0 \mu(x - la) \hat{\mu}_n\}$$

(6a)

$$\sum_n [\hbar c k_n C_n^2 + EC_n^1] e^{ik_n x} = \sum_{l,n} C_n^1 e^{ik_n la} \{v_0 \delta(x - la) - u_0 \mu(x - la) \hat{\mu}_n\}$$

(6b)

where we write $u_0 = m_0 c^2$. For any integrable function $g(x)$ define

$$\hat{g}_n = \int_{-\infty}^{\infty} dx' e^{ik_n x'} g(x').$$

(7)

3
Next, we multiply each of (6a,b) by $\exp[-ik_m x]$ and integrate over $x$, noting that
\[
\int_{-\infty}^{\infty} dx e^{i(k_n-k_m)x} = Na\delta_{n,m} \tag{8a}
\]
\[
\sum_l e^{i(k_n-k_m)l} = N \tag{8b}
\]
to find
\[
\hbar c k_m C^1_m + EC^1_m = \frac{1}{a} \sum_n [C^2_n[v_0 + u_0 \hat{\mu}_n] \tag{9a}
\]
\[
\hbar c k_m C^2_m + EC^2_m = \frac{1}{a} \sum_n [C^1_n[v_0 - u_0 \hat{\mu}_m] \tag{9b}
\]
These can be written
\[
\mathcal{M} C = \begin{pmatrix} v_0 D_2 + u_0 d_2 \hat{\mu}_m \\ v_0 D_1 - u_0 d_1 \hat{\mu}_m \end{pmatrix} \tag{10}
\]
with
\[
D_j = \frac{1}{a} \sum_n C^j_n, \quad d_j = \frac{1}{a} \sum_n C^j_n \hat{\mu}_n \tag{11a}
\]
\[
\mathcal{M} = \begin{pmatrix} \hbar c k_m & E \\ \hbar c k_m \end{pmatrix}, \quad C = \begin{pmatrix} C^1_m \\ C^2_m \end{pmatrix} \tag{12b}
\]
Therefore, by matrix inversion
\[
C^1_m = \frac{1}{\Delta_m(k)} \{ \hbar c k_m [v_0 D_2 + u_0 d_2 \hat{\mu}_m] - E[v_0 D_1 - u_0 d_1 \hat{\mu}_m] \} \tag{13a}
\]
\[
C^2_m = \frac{1}{\Delta_m(k)} \{ \hbar c k_m [v_0 D_1 - u_0 d_1 \hat{\mu}_m] - E[v_0 D_2 + u_0 d_2 \hat{\mu}_m] \} \tag{13b}
\]
where $\Delta_m(k) = \hbar^2 c^2 k_m - E^2$. So, in terms of the quantities
\[
A^*_r = \sum_m \frac{k_m^r}{\Delta_m(k)}, \quad A^*_s = \sum_m \frac{k_m^r \hat{\mu}_m}{\Delta_m(k)}, \quad A^*_s = \sum_m \frac{k_m^r \hat{\mu}_m^*}{\Delta_m(k)} \tag{14}
\]
one has
\[
(1 + E v_0 A^0_1)D_1 - \hbar c v_0 A^1_1 D_2 - E u_0 A^0_2 d_1 - \hbar c u_0 A^0_2 d_2 = 0 \tag{15a}
\]
\[
\hbar c v_0 A^1_1 D_1 - (1 + E v_0 A^0_1)D_2 - \hbar c u_0 A^0_2 d_1 - E u_0 A^0_2 d_2 = 0 \tag{15b}
\]
\[
E v_0 A^0_1 D_1 + \hbar c v_0 A^1_1 D_2 - (1 - E u_0 A^0_1) d_1 + \hbar c u_0 A^1_1 d_2 = 0 \tag{15c}
\]
\[
\hbar c v_0 A^1_1 D_1 - E v_0 A^0_1 D_2 + \hbar c u_0 A^1_1 d_1 - (1 + E u_0 A^0_1) d_2 = 0 \tag{15d}
\]
Consequently, the band structure is given by the roots \( E(k) \) of the \( 4 \times 4 \) determinant

\[
D(k, \eta) = \begin{vmatrix}
1 + E v_0 A_1^0 & -h c v_0 A_1^1 & -E u_0 A_3^0 & -h c u_0 A_3^1 \\
-h c v_0 A_1^1 & 1 + E v_0 A_1^0 & h c u_0 A_3^1 & E u_0 A_3^0 \\
-E v_0 A_3^1 & -h c v_0 A_1^3 & 1 - E u_0 A_3^0 & -h c u_0 A_2^1 \\
-h c v_0 A_3^1 & E v_0 A_3^1 & -h c u_0 A_2^1 & 1 + E u_0 A_2^0 \\
\end{vmatrix}
\] (16)

A word about units is appropriate here. Lengths are given in Bohr radii, \( a_0 \) and we set \( h c = 1 \) so \( \eta = E/hc \), \( v_0 \) and \( u_0 \) are all reciprocal lengths.

The six series \( A_i^r \) can be evaluated analytically; for example:

\[
A_1^0 = \frac{a}{2h^2c^2a\eta} \left[ \frac{\sin(a\eta)}{\cos(a\eta) - \cos(ka)} \right]
\] (17a)

\[
A_1^1 = \frac{a}{2h^2c^2} \left[ \frac{\sin(ka)}{\cos(a\eta) - \cos(ka)} \right]
\] (17b)

**Numerical Example**

As a test case, we set: \( a = 1 \), \( v_0 = 2 \), \( u_0 = 1000 \) and \( b = 0.1 \). Since the ratio \( u_0/v_0 = 500 \) is relatively small, this model may be considered mildly relativistic. The choice \( a = 1 \), which was selected for convenience, means that the lattice is rather dense and may emphasize anomalies. For comparison, we also examine the constant mass version: \( b = 1 \).

The energy levels for the lowest electron band in each case, were found by plotting the determinant (16), with \( k \) specified, as a function of \( \eta \) and recording the lowest positive zero. We note that there may be zeros corresponding to vanishing energy denominators \( \Delta_m(k) = 0 \), i.e. free, zero-mass bands, which are spurious. Lengths are measured in Bohr radii and we have set \( h c = 1 \), so that energies have units of reciprocal length. For model (3) with \( b = 1 \), the lowest band \( E_0(k) \), is shown in Fig. 2. Both bands are continuous and roughly parabolic.

In Fig. (3) we show the next higher band for the two cases. Here again, that for \( b = 1 \) lies above the one for \( b = 0.1 \).

**Discussion**

Since in the constant mass case \( b = 1 \) the lowest band resembles that for the ordinary relativistic Kronig-Penney model [16,17], it appears that the non-local nature of the mass produces no anomalies. However, at the edge of the BZ, \( k = \pi/a \), the energy is driven toward zero, as indicated by a vertical line. The relative nature of the two band structures in Fig. 2 can be heuristically explained as follows: At low wave vector \( k \), for the sinusoidal case the particle has long wave length and "senses" only tan average mass, so the bands nearly merge, but separate at higher \( k \) value where the particle wave length is small enough that the mass variation is detectable. In. which case the energy is depressed.
Figure 2: Lowest particle band: $a = 1$, $b = .1$(lower curve), $b = 1$(upper curve)
$v_0 = 2$, $u_0 = 1000$.

Figure 3: First excited particle band: $a = 1$, $b = .1$(initially upper curve),
$b = 1$( lower curve) $v_0 = 2$, $u_0 = 1000$. 
At the zone boundary the particle and mass wavelengths are in resonance and the particle velocity is reduced.

As pointed out in [18] the upper and lower components of the two-component spinor here are particle and anti-particle wave functions, resp. Hence the negative roots of (16) correspond to positron energies. The fundamental bands of the two cases considered here are shown in Fig.4.

In conclusion, a version of the relativistic Kronig-Penney model has been constructed which may be suitable for exploring the effects of variation of effective masses in semiconductor structures. It incorporates the unusual replacement of the mass as a non-local operator, but this does not appear to introduce anomalies in the band structure where the mass has purely sinusoidal variation. In a future report we hope to consider the more usual case where the mass is constant but its value varies from cell to unit cell. Finally, it is worth pointing out that the model is easily extended to two and three dimensions.

Figure 4: Antiparticle band: \( a = 1 \), \( b = .1 \)(initially upper curve), \( b = 1 \)(initially lower curve) \( v_0 = 2 \), \( u_0 = 1000 \).
