DETERMINANTAL ELLIPTIC SELBERG INTEGRALS

HJALMAR ROSENDREN

Dedicated to Christian Krattenthaler on his 60th birthday

Abstract. The classical Selberg integral contains a power of the Vandermonde determinant. When that power is a square, it is easy to prove Selberg’s identity by interpreting it as a determinant of one-variable integrals. We give similar proofs of summation and transformation formulas for continuous and discrete elliptic Selberg integrals. In the continuous case, the same proof was previously given by Noumi. Special cases of the resulting identities have found applications in combinatorics.

1. Introduction

In 1944, Selberg proved the integral evaluation \[ (1.1) \]

\[
\int_{x_1, \ldots, x_n = 0}^{1} \prod_{1 \leq j < k \leq n} |x_j - x_k|^{2c} \prod_{j=1}^{n} x_j^{a-1}(1 - x_j)^{b-1} \, dx_j = \prod_{j=1}^{n} \frac{\Gamma(a + (j - 1)c)\Gamma(b + (j - 1)c)\Gamma(1 + jc)}{\Gamma(a + b + (n + j - 2)c)\Gamma(1 + c)},
\]

which had appeared in slightly different form in his earlier paper \[ S1 \]. Here, \( \Gamma \) is the classical gamma function, not the elliptic gamma function that will appear below. This holds under the natural convergence conditions

\[
\text{Re}(a) > 0, \quad \text{Re}(b) > 0, \quad \text{Re}(c) > -\min\left(\frac{1}{n}, \frac{\text{Re}(a)}{n - 1}, \frac{\text{Re}(b)}{n - 1}\right).
\]

The Selberg integral plays a fundamental role in random matrix theory and analysis on classical groups, and has been generalized in many directions \[ FW \].

The general case of \[ (1.1) \] is quite deep. It is instructive to note that in 1963 Mehta and Dyson \[ MD \] conjectured that

\[
\int_{x_1, \ldots, x_n = -\infty}^{\infty} \prod_{1 \leq j < k \leq n} |x_j - x_k|^{2c} \prod_{j=1}^{n} e^{-x_j^2/2} \, dx_j = (2\pi)^{n/2} \prod_{j=1}^{n} \frac{\Gamma(1 + jc)}{\Gamma(1 + c)}. \quad (1.2)
\]

Although this was republished as a conjecture several times, no proof was found until it was recognized as a degenerate case of \[ (1.1) \] in the late 1970s, see \[ FW \].

Mehta and Dyson could prove \[ (1.2) \] for \( c = 1/2, 1 \) and 2, which are the most important cases in random matrix theory. Their discussion of the case \( c = 1 \) is just one sentence: “The case \( \beta = 2 \) is the easiest; one needs only to introduce

Hermite polynomials and exploit their orthogonality properties”. For our purpose, it is useful to explain this starting from the algebraic identity [A] (see [F] for the history of this result)

\[
\det_{1 \leq j, k \leq n} \left( \int f_j(x) g_k(x) \, d\mu(x) \right) = \frac{1}{n!} \int \det_{1 \leq j, k \leq n} (f_j(x_k)) \det_{1 \leq j, k \leq n} (g_j(x_k)) \, d\mu(x_1) \cdots d\mu(x_n),
\]

which holds for any linear functional \( f \mapsto \int f(x) \, d\mu(x) \). If \( f_j \) and \( g_j \) are monic polynomials of degree \( j - 1 \), then the determinants on the right are column-equivalent to Vandermonde determinants and we obtain

\[
\det_{1 \leq j, k \leq n} \left( \int f_j(x) g_k(x) \, d\mu(x) \right) = \frac{1}{n!} \int \prod_{1 \leq j < k \leq n} (x_j - x_k)^2 \, d\mu(x_1) \cdots d\mu(x_n). \tag{1.4}
\]

If we now choose \( f_j = g_j \) as orthogonal with respect to \( d\mu \), then the left-hand side of (1.4) reduces to the product of the squared norms of the first \( n \) monic orthogonal polynomials. The identity (1.4) is then a classical result known to Heine [I, Cor. 2.1.3]. The case of Jacobi and Hermite polynomials give the case \( c = 1 \) of (1.1) and (1.2), respectively.

There is a less well-known but even more elementary proof of the case \( c = 1 \) of (1.1), based on varying the parameters \( a \) and \( b \). This proof is more relevant to the present work, so we will explain it in detail. Let \( I_{jk} \) denote the one-variable case of (1.1), after replacing \((a, b)\) with \((a + j - 1, b + n - k)\). By Euler’s beta integral evaluation,

\[
I_{jk} = \int_0^1 x^{a+j-2}(1-x)^{b+n-k-1} \, dx = \frac{\Gamma(a+j-1)\Gamma(b+n-k)}{\Gamma(a+b+n+j-k-1)}.
\]

Consider the determinant \( D = \det_{1 \leq j, k \leq n}(I_{jk}) \). It can be identified with the left-hand side of (1.4), where \( f_j(x) = x^{j-1} \), \( g_j(x) = (1-x)^{n-j} \) and

\[
\int f(x) \, d\mu(x) = \int_0^1 f(x) x^{a-1}(1-x)^{b-1} \, dx.
\]

Although \( g_j \) is not monic of degree \( j - 1 \), the sign changes coming from replacing \((x-1)^{j-1}\) by \((1-x)^{n-j}\) cancel, so (1.4) still holds. Thus, the case \( c = 1 \) of (1.1) can be expressed as \( n!D \). This is another instance of the Vandermonde determinant. The gamma functions in the numerator can be pulled out, and the denominator can be expressed as

\[
\frac{1}{\Gamma(a + b + n + j - k - 1)} = \frac{p_{k-1}(j)}{\Gamma(a + b + n + j - 2)},
\]
where $p_{k-1}$ is a monic polynomial of degree $k - 1$, so that

$$\det_{1 \leq j, k \leq n} (p_{k-1}(j)) = \prod_{1 \leq j < k \leq n} (k - j) = \prod_{j=1}^{n} (j - 1)!.$$ 

We conclude that

$$n!D = \prod_{j=1}^{n} \frac{\Gamma(a + j - 1)\Gamma(b + j - 1)j!}{\Gamma(a + b + n + j - 2)},$$

which agrees with the right-hand side of (1.1) for $c = 1$.

The same method works for many variations of the $c = 1$ Selberg integral; the integration may be continuous, infinite discrete or finite, and the integrands may live at the rational, trigonometric or elliptic level. (In the most common notation, $c = 1$ corresponds to $t = q$ at the trigonometric and elliptic level.) One can also prove transformation formulas, stating that two Selberg-type integrals are equal. The purpose of the present note is to illustrate this method with two examples: an elliptic Selberg integral conjectured by Van Diejen and Spiridonov [DS1] and a transformation formula for discrete Selberg integrals conjectured by Warnaar [W]. Both these identities were first proved by Rains [R1, R3]; the second one also independently by Coskun and Gustafson [CG].

We are not claiming that our proofs are new, and the present paper should be viewed as expository. It is clear from our correspondence with Rains that he is aware of similar proofs. Moreover, Noumi [N] gave a determinantal proof of the transformation formula stated as (2.8) below. This generalizes the proof of the continuous integration formula given below and is completely parallel to our proof of the discrete transformation formula. The main motivation for writing the present note is that we have seen several recent papers where the case $t = q$ of Warnaar’s identities for discrete Selberg integrals are applied [BK, BKW, FHX, KS] but the reader is referred to work on the general case [CG, R1, Ro1] for the proof. Even though it is known to some experts in the field, it seems useful to point out to a wider community that much easier proofs exist. We also hope that the same method can be used to find new results. In particular, we think of quadratic and cubic transformation formulas for $c = 1$ Selberg-type integrals, which may perhaps even admit extensions to general $c$. In this direction, we mention that several quadratic transformations of elliptic Selberg integrals are given in [R4, R5]. Quadratic summations for $c = 1$ discrete Selberg integrals appear in connection with tiling problems [C, Ro2].

Acknowledgement: It is a pleasure to dedicate this piece to Christian Krattenthaler, a virtuoso of determinants, hypergeometry and much more. I am very grateful for his patience and support over the years. I also thank Masatoshi Noumi, Eric Rains and Ole Warnaar for useful correspondence.
2. Continuous Selberg Integrals

We recall the standard notation of elliptic hypergeometric functions. We fix two parameters \( p \) and \( q \) with \(|p|, |q| < 1\), which we suppress from the notation. Ruijsenaars’ elliptic gamma function \([Ru]\) is given by

\[
\Gamma(z) = \prod_{j,k=1}^{n} \frac{1 - p^{j+1}q^{k+1}/z}{1 - p^j q^k z}.
\]

It satisfies the functional equation

\[
\Gamma(qz) = \theta(z) \Gamma(z)
\]

and, more generally,

\[
\Gamma(q^k z) = (z)_k \Gamma(z),
\]

where the theta function and elliptic shifted factorials are given by

\[
\theta(z) = \prod_{j=0}^{\infty} (1 - p^j z) \left(1 - \frac{p^{j+1}}{z}\right), \quad (z)_k = \prod_{j=0}^{k-1} \theta(zq^j).
\]

Repeated variables in each of these functions is a short-hand for products. For instance,

\[
\Gamma(z_1, \ldots, z_m) = \Gamma(z_1) \cdots \Gamma(z_m),
\]

\[
\Gamma(z^\pm w^\pm) = \Gamma(zw) \Gamma(z/w) \Gamma(w/z) \Gamma(1/wz).
\]

For introductions to elliptic hypergeometric series, we refer to \([GR, Ro3]\). We will make heavy use of elementary identities that can be found in these sources.

The elliptic Selberg integral is the evaluation

\[
\frac{C^n}{2^{n!n}} \int \prod_{1 \leq j < k \leq n} \frac{\Gamma(t^{z_j^+} z_k^+)}{\Gamma(z_j^+ z_k^+)} \prod_{j=1}^{n} \frac{\Gamma(t^j z_j^+)}{\Gamma(z_j^+ z_j^+)} \frac{dz_j}{2\pi i z_j} = \prod_{m=1}^{n} \left(\frac{\Gamma(t^m)}{\Gamma(t)} \prod_{1 \leq j < k \leq 6} \Gamma(t^{m-1} t^j t^k)\right), \quad (2.3)
\]

where the parameters satisfy the balancing condition \( t^{2n-2} t_1 t_2 t_3 t_4 t_5 t_6 = pq \) and

\[
C = \prod_{j=1}^{n} (1 - p^j)(1 - q^j).
\]

If \(|t| < 1\) and \(|t_j| < 1\) for all \(j\), the integration is over \(|z_1| = \cdots = |z_n| = 1\); this condition may be relaxed if the contour is deformed appropriately. The evaluation \((2.3)\) contains the classical Selberg integral \(\text{[1.1]}\) as a limit, see \([R2]\).

The case \(p = 0\) of \((2.3)\) is due to Gustafson \([G]\) and the case \(n = 1\) to Spiridonov \([Sp1]\). The general case was conjectured by Van Diejen and Spiridonov \([DS1]\) and first proved by Rains \([R3]\). Another proof follows by combining the results.
of [DS2, Sp2] and a third proof is given in [IN2]. For a quantum field theory interpretation of (2.3), see [SV, §12.3.2].

The parameter $c$ in (1.1) corresponds to $\log q t$ in (2.3). In particular, $c = 1$ corresponds to $t = q$. We proceed to give a simple proof of this special case. Let $I_{jk}$ denote the case $n = 1$ of (2.3), after the substitutions $(t_1, t_2, t_3, t_4) \mapsto (t_1 q^{j-1}, t_2 q^{n-j}, t_3 q^{k-1}, t_4 q^{n-k})$. The balancing condition is then

$$q^{2n-2} t_1 t_2 t_3 t_4 t_5 t_6 = pq.$$  \hfill (2.4)

By (2.2), the resulting integral can be written as

$$I_{jk} = \frac{C}{2} \int (t_1 z^\pm)_{j-1} (t_2 z^\pm)_{n-j} (t_3 z^\pm)_{k-1} (t_4 z^\pm)_{n-k} \prod_{j=1}^6 \frac{\Gamma(t_j z^\pm)}{\Gamma(z^\pm)} \frac{dz}{2\pi i z}.$$  

Let $D = \det_{1 \leq j,k \leq n}(I_{jk})$. Then, (2.3) gives

$$D = \frac{C^n}{2^n n!} \int d(t_1, t_2) d(t_3, t_4) \prod_{k=1}^n \prod_{j=1}^6 \frac{\Gamma(t_j z_k^\pm)}{\Gamma(z_k^\pm)} \frac{dz_k}{2\pi i z_k},$$

where

$$d(a, b) = \det_{1 \leq j,k \leq n} ((az_k^\pm)_{j-1} (bz_k^\pm)_{n-j}).$$  \hfill (2.5)

By Warnaar’s determinant evaluation [W, Lemma 5.3],

$$d(a, b) = b^\binom{n}{2} q^\binom{n}{3} \prod_{j=1}^n (q^j a/b, q^{n-j} ab)_{j-1} \prod_{1 \leq j < k \leq n} z_k^{-1} \theta(z_k z_j^\pm).$$  \hfill (2.6)

Note also that

$$\prod_{1 \leq j < k \leq n} (z_k^{-1} \theta(z_k z_j^\pm))^2 = \prod_{1 \leq j < k \leq n} \frac{\Gamma(z_j^\pm z_k^\pm)}{\Gamma(z_j^\pm z_k^\pm)}.$$  

This gives

$$D = (t_2 t_4)^\binom{n}{2} q^\binom{n}{3} \prod_{j=1}^n (q^j t_1/t_2, q^{n-j} t_1 t_2, q^{j-1} t_3/t_4, q^{n-j} t_3 t_4) \times \frac{C^n}{2^n n!} \int \prod_{1 \leq j < k \leq n} \frac{\Gamma(q z_j^\pm z_k^\pm)}{\Gamma(z_j^\pm z_k^\pm)} \prod_{j=1}^n \prod_{k=1}^6 \frac{\Gamma(t_k z_j^\pm)}{\Gamma(z_j^\pm)} \frac{dz_j}{2\pi i z_j},$$  \hfill (2.7)

where we recognize the integral as the case $t = q$ of (2.3).

On the other hand, the case $n = 1$ of (2.3) (that is, Spiridonov’s elliptic beta integral) gives

$$I_{jk} = \Gamma(t_1 t_2 q^{n-1}, t_1 t_3 q^{j+k-2}, t_1 t_4 q^{n+j-k-1}, t_1 t_5 q^{j-1}, t_1 t_6 q^{j-1}) \times \Gamma(t_2 t_3 q^{n-j+k-1}, t_2 t_4 q^{2n-j-k}, t_2 t_5 q^{n-j}, t_2 t_6 q^{n-j}, t_3 t_4 q^{n-1}) \times \Gamma(t_3 t_5 q^{k-1}, t_3 t_6 q^{k-1}, t_4 t_5 q^{n-k}, t_4 t_6 q^{n-k}, t_5 t_6).$$
Most of the factors are independent of either \( j \) or \( k \) and can thus be pulled out of the determinant. Using again (2.2), we are left with

\[
D = \Gamma(t_1t_2q^{n-1}, t_3t_4q^{n-1}, t_5t_6)^n \prod_{m=1}^{n} \prod_{1 \leq j < k \leq 6 \atop (j,k) \neq (1,2), (3,4), (5,6)} \Gamma(t_jt_kq^{m-1})
\]

\[
\times \det_{1 \leq j,k \leq n} \left( (t_1t_2q^{k-1}, t_1t_4q^{n-k})_{j-1}(t_2t_3q^{k-1}, t_2t_4q^{n-k})_{n-j} \right).
\]

The final determinant is of the form (2.6), with \( a = t_1 \sqrt{t_3t_4q^{n-1}}, b = t_2 \sqrt{t_3t_4q^{n-1}}, z_k = q^{k-1} \sqrt{q^{1-n}t_3/t_4} \). Using (2.6) and also (2.4) to write \((q^{n-j}a)_{j-1} = (t_5t_6)_{j-1}\), we obtain after simplification

\[
D = (t_2t_4)^{(n)} q^{2(n)} \Gamma(t_1t_2q^{n-1}, t_3t_4q^{n-1})^n \prod_{m=1}^{n} \prod_{1 \leq j < k \leq 6 \atop (j,k) \neq (1,2), (3,4)} \Gamma(t_jt_kq^{m-1})
\]

\[
\times \prod_{j=1}^{n} (q, q^{j-n}t_1/t_2, q^{j-n}t_3/t_4)_{j-1}.
\]

Comparing this with (2.7) yields the case \( t = q \) of (2.3).

Essentially the same proof works for the case \( t = q \) of Rains’ integral transformation [R3]

\[
\int \prod_{1 \leq j < k \leq n} \frac{\Gamma(tz_j^z_k)}{\Gamma(z_j^z_k)} \prod_{k=1}^{4} \frac{\Gamma(t_kz_j^z_k, u_kz_j^z_k)}{\Gamma(z_j^z_k)} \frac{dz_j}{2\pi iz_j}
\]

\[
= \prod_{m=1}^{n} \prod_{1 \leq j < k \leq 4} \Gamma(t^{m-1}t_jt_k, u^{m-1}u_ju_k)
\]

\[
\times \int \prod_{1 \leq j < k \leq n} \frac{\Gamma(tz_j^z_k)}{\Gamma(z_j^z_k)} \prod_{k=1}^{4} \frac{\Gamma(t_kvz_j^z_k, u_kv^{-1}z_j^z_k)}{\Gamma(z_j^z_k)} \frac{dz_j}{2\pi iz_j}, \tag{2.8}
\]

where \( v^2 = pq/t^{n-1}t_1t_2t_3t_4 = t^{n-1}u_1u_2u_3u_4/pq \). The details can be found in [N], where the integral (2.8) is interpreted as a tau function for the elliptic Painlevé equation.

### 3. Discrete Selberg Integrals

The integral evaluation (2.3) and transformation (2.8) have analogues for finite sums, which were conjectured by Warnaar [W] prior to the discovery of the continuous versions. Warnaar’s summation can be obtained from the integral evaluation (2.3) through residue calculus [DS1] (presumably, a similar argument applies to the transformations). The conjectured summation was proved in [Ro1], see also [IN1], and the more general transformation in [CG, R1].
As one would expect, the case \( t = q \) of Warnaar’s identities admit simple determinantal proofs. We will focus on the transformation, which can be written as

\[
\sum_{0 \leq x_1 < x_2 < \cdots < x_n \leq N} \prod_{1 \leq j < k \leq n} \left( q^{x_j} \theta(q^{x_k-x_j}) \theta(aq^{x_j+x_k}) \right)^2 \times \prod_{j=1}^{n} \left( \frac{\theta(aq^{2x_j})}{\theta(a)} \frac{(a, b, c, d, e, f, g, q^{-N})_{x_j}}{(q, aq/b, aq/c, aq/d, aq/e, aq/f, aq/g, aq^{N+1})_{x_j}} q^{x_j} \right) = \left( \frac{a}{\lambda} \right)^{(N+1-n)n} \prod_{j=1}^{n} \left( \frac{(b, c, d)_{j-1}(\lambda q/e, \lambda q/f, \lambda q/g)_{N+1-j}}{(\lambda b/a, \lambda c/a, \lambda d/a)_{j-1}(aq/e, aq/f, aq/g)_{N+1-j}} \right) \times \prod_{0 \leq x_1 < x_2 < \cdots < x_n \leq N} \prod_{1 \leq j < k \leq n} \left( q^{x_j} \theta(q^{x_k-x_j}) \theta(aq^{x_j+x_k}) \right)^2 \times \prod_{j=1}^{n} \left( \frac{\theta(\lambda q^{2x_j})}{\theta(\lambda)} \frac{(\lambda, \lambda b/a, \lambda c/a, \lambda d/a, e, f, g, q^{-N})_{x_j}}{(q, aq/b, aq/c, aq/d, \lambda q/e, \lambda q/f, \lambda q/g, \lambda q^{N+1})_{x_j}} q^{x_j} \right),
\]

where \( bcdefg = q^{4+N-2n}a^3 \) and \( \lambda = a^2q^{2-n}/bcd \). When \( aq = cd \), the factor \( (\lambda b/a)_{x_n} = (q^{1-n})_{x_n} \) on the right-hand side vanishes unless \( x_n \leq n - 1 \), so the sum reduces to the term with \( (x_1, \ldots, x_n) = (0, 1, \ldots, n - 1) \). After a change of variables, this gives the case \( t = q \) of Warnaar’s discrete Selberg integral, namely,

\[
\sum_{0 \leq x_1 < x_2 < \cdots < x_n \leq N} \prod_{1 \leq j < k \leq n} \left( q^{x_j} \theta(q^{x_k-x_j}) \theta(aq^{x_j+x_k}) \right)^2 \times \prod_{j=1}^{n} \left( \frac{\theta(aq^{2x_j})}{\theta(a)} \frac{(a, b, c, d, e, f, g, q^{-N})_{x_j}}{(q, aq/b, aq/c, aq/d, aq/e, aq^{N+1})_{x_j}} q^{x_j} \right) = b^{(N+1-n)n} \frac{1}{q^{n(n-1)(3N+1-2n)}} \left( \frac{aq}{q} \right)^n \times \prod_{j=1}^{n} \left( \frac{(aq^{2-j}/bc, aq^{2-j}/bd, aq^{2-j}/bc)_{N+1-j}}{(aq^{2-j}/bc, aq^{2-j}/bd, aq^{2-j}/bc)_{N+1-j}} \right),
\]

which holds for \( bcde = q^{N+3-2n}a^2 \).

We will give a simple proof of (3.1), which is completely parallel to the continuous case. We need the case \( n = 1 \), which is the one-variable elliptic Bailey transformation. It first appeared (rather implicitly and with some restrictions on the parameters) in the work of Date et al. on Baxter’s elliptic solid-on-solid model [D] and was proved in general by Frenkel and Turaev [FT], see [GR] [Ro3] for more elementary proofs.
Let $S_{jk}$ denote the case $n = 1$ of (3.1), after the substitutions $(b, c, e, f) \mapsto (b q^{j-1}, c q^{n-j}, e q^{k-1}, f q^{n-k})$. After some elementary manipulation, we may write

$$S_{jk} = \sum_{x=0}^{N} \frac{\theta(a q^{2x})}{\theta(a)} \frac{(a, b, c, d, e, f, g, q^{-N}) \cdot (q, a q/b, a q/c, a q/d, a q/e, a q/f, a q/g, a q^{N+1})}{q^{(2n-1)}} \times \frac{(b q^x, b q^{-x}/a)_{j-1}(c q^x, c q^{-x}/a)_{n-j}(e q^x, e q^{-x}/a)_{k-1}(f q^x, f q^{-x}/a)_{n-k}}{(b, b/a)_{j-1}(c, c/a)_{n-j}(e, e/a)_{k-1}(f, f/a)_{n-k}}.$$

Let $D = \det_{1 \leq j, k \leq n}(S_{jk})$. We expand $D$ using the Cauchy–Binet identity

$$D = \frac{1}{\prod_{j=1}^{n}(b, b/a, c, c/a, e, e/a, f, f/a)_{j-1}} \times \sum_{0 \leq x_1 < x_2 < \cdots < x_N \leq N} \prod_{k=1}^{n} \frac{\theta(a q^{2x_k})}{\theta(a)} \frac{(a, b, c, d, e, f, g, q^{-N})_{x_k} q^{x_k(2n-1)}}{(q, a q/b, a q/c, a q/d, a q/e, a q/f, a q/g, a q^{N+1})_{x_k}} \times \delta(b, c) \delta(e, f),$$

where

$$\delta(b, c) = \det_{1 \leq j, k \leq n} \left((b q^x, b q^{-x}/a)_{j-1}(c q^x, c q^{-x}/a)_{n-j}\right).$$

This determinant is of the form (2.5), with $(a, b, z_k)$ replaced by $(b/\sqrt{a}, c/\sqrt{a}, \sqrt{a} q^x)$. Using (2.6) and simplifying, we find that $D$ equals the left-hand side of (3.1) times

$$\left(\frac{cf}{a^2}\right)^{\binom{1}{2}} q^{\binom{2}{a}} \sum_{j=1}^{N} \frac{q^{j-nb/c, a q^{n-j}bc/a, q^{j-n}e/f, q^{n-j}e/f/a}_{j-1}}{(b, b/a, c, c/a, e, e/a, f, f/a)_{j-1}}.$$  

(3.3)

Repeating the same computation but starting from the alternative expression

$$S_{jk} = \left(\frac{a}{\lambda}\right)^N \frac{(a q^{2-k}/e, \lambda q^{1-n+k}/f, \lambda q/g)_{N}}{(\lambda q, a q^{2-k}/e, a q^{1-n+k}/f, a q/g)_{N}} \times \sum_{x=0}^{N} \frac{\theta(\lambda q^{2x})}{\theta(\lambda)} \frac{(\lambda, \lambda b/a, \lambda c/a, \lambda d/a, e, f, g, q^{-N})_{x}}{(q, a q/b, a q/c, a q/d, \lambda q/e, \lambda q/f, \lambda q/g, \lambda q^{N+1})_{x}} \times \frac{(\lambda b q^x/a, b q^{-x}/a)_{j-1}(\lambda c q^x/a, c q^{-x}/a)_{n-j}(e q^x, e q^{-x}/\lambda)_{k-1}(f q^x, f q^{-x}/\lambda)_{n-k}}{(\lambda b/a, b/a)_{j-1}(\lambda c/a, c/a)_{n-j}(e, e/\lambda)_{k-1}(f, f/\lambda)_{n-k}},$$

we obtain after simplification the same prefactor (3.3) times the right-hand side of (3.1). This completes the proof of (3.1).
