INTRODUCTION
Alkyd resins are very important materials in coating industries. They have been used in varnishes, composite coatings, lacquers and adhesives industries (Dolui, 2015; Meneghetti and Meneghetti, 2015). Triglyceride (TG) based vegetable oil can be used to synthesize alkyd resins. To synthesize alkyd resin in the laboratory, alcoholsysis is the first step, which followed by esterification (Mutar and Hassan, 2017). For the alcoholysis process, the most common polyol used is glycerol, whereas, for esterification phthalic anhydride is widely used (Ong et al., 2018). Different types of catalysts like lead(II) oxide (PbO), potassium hydroxide (KOH), zinc oxide (ZnO), lithium oxide (LiO), calcium oxide (CaO) and sodium hydroxide (NaOH) can be used for the reactions. The reported reaction temperature is around 240°C. The conversion in the first step, after the alcoholsysis, the reaction products usually contain 40%-60% monoglyceride (MG) (Rarokar et al., 2017). This MG is required to homogenise the reaction medium which is a favourable condition for the formation of monoglyceride (MG) and diglyceride (DG) during the synthesis and their ratio may have a significant role on the properties of the polyalkyds. The goal of the present article was to investigate the effect of MG to DG ratio on alkyd resin synthesised from palm oil by alcoholsysis-polyesterification reactions catalysed by homo-hetero catalytic system. Different ratios of MG:DG were obtained from alcoholysis reaction by taking samples at different reaction times. The formation of the alkyd resin was confirmed by Fourier transform infrared spectroscopy (FTIR) with the presence of ester group (C-O-C). The molecular weight ($M_w$) of alkyd resin was determined by gel permeation chromatography (GPC). The alkyd resin prepared at higher MG:DG ratio exhibited higher initial rate of polyesterification reaction with higher $M_w$. In addition, the film of alkyd resin prepared from higher MG:DG ratio presented better pencil hardness and chemical resistivity.

ABSTRACT
Alcoholysis and esterification are useful methods to prepare polyalkyds from vegetable oils. Reaction parameters and different concentration of raw materials have showed a significant role on the properties of the formulated polyalkyds. The formation of monoglyceride (MG) and diglyceride (DG) during the synthesis and their ratio may have a significant role on the properties of the polyalkyds. The goal of the present article was to investigate the effect of MG to DG ratio on alkyd resin synthesised from palm oil by alcoholsysis-polyesterification reactions catalysed by homo-hetero catalytic system. Different ratios of MG:DG were obtained from alcoholysis reaction by taking samples at different reaction times. The formation of the alkyd resin was confirmed by Fourier transform infrared spectroscopy (FTIR) with the presence of ester group (C-O-C). The molecular weight ($M_w$) of alkyd resin was determined by gel permeation chromatography (GPC). The alkyd resin prepared at higher MG:DG ratio exhibited higher initial rate of polyesterification reaction with higher $M_w$. In addition, the film of alkyd resin prepared from higher MG:DG ratio presented better pencil hardness and chemical resistivity.

for the second step, polyesterification. MG and diglyceride (DG) reaction with polyacid can form the linear polymer. The chain length of the alkyd resin is related to MG:DG ratio, where DG acts as a chain stopper.

Several numbers of researches have investigated the polylakdys preparation from vegetable oils using the two-step process, alcoholysis and esterification (Beg et al., 2019). Optimisation of the reaction parameters and characterisation of the synthesised polylakdys were the focus of these works. Some of the works highlighted about the drying and non-drying properties of the vegetable oils. In addition, further modification of the polylakdys was also suggested. Based on the previous results, it was hypothesised that the esterification can be influenced by the factor of MG and DG ratio. Bearing this in mind, the current research work has been developed. Moreover, to the best of our knowledge, other researchers preferred the methanol solubility method during alcoholysis reaction, but this method does not quantify the MG concentration. Recently, our laboratory prepared MG from palm oil via copper(II) oxide - sodium hydroxide (CuO-NaOH) catalyst system and using high performance liquid chromatography (HPLC) method to quantify the MG concentration (Ong et al., 2016a). The effect of MG:DG ratio on alkyd preparation has been undermined throughout the literature. In this context, the goal of this work is to investigate the effect of MG:DG ratio on polyesterification reaction. Moreover, the pencil hardness and chemical resistivity of the alkyd films were elucidated.

**METHODOLOGY**

**Materials**

The chemicals and reagents used in this study were ethanol (99.9%), copper (II) chloride salt (CuCl₂.2H₂O), standard 1-oleoyl-rac-glycerol (≥99%), NaOH, hydrazine monohydrate (64%), glycerol, cobalt octoate, KOH, 1,2-dioleoyl-sn-glycerol (≥97%), methyl ethyl ketone peroxide (MEKP), styrene, and glyceryl trioleate (≥99%) which were purchased from Sigma-Aldrich, Malaysia. Acetone and acetonitrile were procured from Merck (Malaysia) Sdn. Bhd. Refined palm oil was kindly supplied by Malaysian Palm Oil Board (MPOB), Malaysia. All chemicals were used in this research as they were received. *Figure 1* depicts the flow diagram of methodology for this study.

**Preparation of CuO Nanoparticles**

The CuO nanoparticles were synthesised at ambient temperature by sol–gel method (Ong et al., 2015a; 2015b). First of all, a fixed amount of CuCl₂.2H₂O was dissolved in 44 ml of glycerol. After that, 6 ml of hydrazine solution was added into the mixture dropwise. The concentration of copper was maintained from 100-300 mg litre⁻¹. Hydrazine solution (7.062 mM) was prepared earlier by diluting 64% of hydrazine monohydrate in ethanol.

![Flow diagram of methodology.](image-url)
Preparation of Monoglyceride

Alcoholysis process was adopted to prepare the MG from palm oil and glycerine. In the process, nearly 100 g of palm oil was poured in a beaker with CuO nano particles (22.2 g). The mixture was stirred continuously and heated at 240°C. After that, additionally, a little amount of NaOH (0.3 g) was added. The reaction was conducted in a continuous flow of nitrogen gas into the reaction chamber.

Preparation of Alkyd Resin

After the completion of alcoholysis reaction, the temperature of the reactor was reduced to 140°C. After that, 38.7 g of phthalic anhydride was added into the reactor. Then, the temperature of the reactor was increased to 240°C. The acid value (AV) of the products was determined by ASTM D1639-90, at different times during the propagation of the reaction. When the AV reached to nearly 10 mg KOH g⁻¹, then the reactor was cooled down. To investigate the effect of MG:DG ratio on polyesterification reaction, the alcoholysis reaction was stopped at different times (30, 40 and 60 min) and the polyesterification reaction was conducted as mentioned above. The synthesis pathway of alkyd resin is presented in Figure 2.

High Performance Liquid Chromatography (HPLC)

The HPLC (Agilent 1200 Series) was used to quantify the reaction products. The machine was equipped with refractive index detector (RID) and diode-array detectors (DAD). A Zorbax C18 column with the specification of 4.6 m x 250 mm (5 μm) was used for the analysis. The flow rate was maintained at 1.0 ml min⁻¹. The detector and the column temperature were fixed to 40°C and 35°C, respectively. A mixture of acetone and acetonitrile (65:35, v/v) was used as a carrier of the sample through the column. Another composition of acetone and acetonitrile (1:1, v/v) was used to dissolve the sample. The volume of the injection was 10 μl. The standards of MG, DG and TG were used to quantify the reaction products. Different concentrations at 300, 800, 1000, 2000, 5000, 8000 and 10 000 ppm were used to prepare the calibration curves. At least three different runs were carried out for each analysis. A slow agitation and slightly warmed samples were used for the analysis to avoid the separation of the phases. The experimental deviations were considered less than 5% for the content of MG, DG and TG.

Degree of Polymerisation Determination

During the esterification reaction, the reaction products were collected for the AV testing. The titrimetric value was used for the determination of AV. The AV was used to calculate the extent of the reaction, P. The average degree of polymerisation (DP) was calculated using the value of P. The following equations were used for the calculation:

\[ P = \frac{(C_0 - C_t)}{C_0} \]  
\[ DP = (1 - P)^{\frac{1}{2}} \]

![Figure 2. Synthesis pathway of palm oil-based alkyd resin (alcoholysis-polyesterification process).](image-url)
where, $C_0 = \text{acid value at the beginning}$ and $C_t = \text{acid value at the time } t, t = \text{reaction time}$.

**Molecular Weight ($M_w$) Determination**

A waters gel permeation chromatography (GPC) was used to determine the molecular weight ($M_w$) of the formulated alkyd resins. The testing was performed at room temperature using tetrahydrofuran as an eluent. Linear polystyrene was used for the calibration. Waters empower software was used for the data analysis.

**FTIR Spectroscopy**

The functional groups of palm oil and the resin (A-60) were observed by a Fourier transform infrared (FTIR) spectroscopy, model- Spectrum 100, Perkin Elmer. The scanning range was 600 to 4000 cm$^{-1}$ with a resolution of 4 cm$^{-1}$.

**Curing Process**

MEKP was used for the curing process of the prepared alkyd resins. Exactly, 10 g of alkyd resin was poured in a beaker. After that, 4 phr of MEKP, 30 phr of styrene and 2 phr of cobalt oxalate was mixed with the resin and stirred for 10 min at 60°C. After that, the resin mixture was poured to a petri dish for the curing process. The samples were observed and fingertip was used to check whether the films had solidified or not. The spot less samples were accounted as the cured film eventually.

**Pencil Hardness Testing**

The hardness of the formulated alkyd films was determined by a set of pencils (6B to 6H) and pencil hardness tester, model- B-3084. To test the samples, different pencils were placed inside the tester at 45° angle and dragged onto the surface of the films. If the pencils were able to make a scratch onto the surface of the films, they are considered as ‘fail’. The negative result of this are considered as ‘pass’. The methods are stated in ASTM D3363.

**Chemical Resistivity Test of Alkyd Film**

For chemical resistivity testing, four different types of solution were prepared. The different types chemical solution were distilled water, aqueous Hydrogen chloride (HCL) (5%), brine solution (5%) and NaOH (5%). The prepared alkyd films which weighted nearly 0.5 g were immersed into the solutions at ambient temperature for one day only. After that, the weights of the samples were measured. A qualitative performance according to their appearance after the immersion period was noted as the observations from the testing.

**RESULTS AND DISCUSSION**

**Preparation of Alkyd Resin**

The MG, DG and TG concentration at different time intervals were determined by HPLC and the data are presented in Figure 3. It can be seen that, TG concentration dropped sharply as the reaction progressed and reached after 30 min of reaction. The MG and DG concentrations had increased and reached plateau after 40 and 30 min, respectively. In order to investigate the effect of MG:DG ratio on polyesterification reaction, alcoholysis reaction was stopped at 30, 40 and 60 min and proceeded to polyesterification reaction. The samples at 30, 40 and 60 min were labeled as A-30, A-40 and A-60, respectively.

The AV of the reaction products was checked frequently to trace the progress of polyesterification. The unreacted carboxylic acid functional groups were estimated for this purpose. Figure 4 presents the AV of the reaction products at different time intervals to show the effects of MG:DG ratio on polyesterification. The primary and secondary hydroxyl group show different reactivity (Ong et al., 2016b). Therefore, the AV of the reaction products changed as the reaction progressed. It was found that the AVs decreased as the reaction proceeded. The rate of decrease of AV was faster in the early period of the polyesterification compare to the later period. This is because of the superior reactivity of the primary hydroxyl group. The similar trends were also reported elsewhere. The viscosity of the reaction products increased due to the possible formation of a 3D crosslinked network structure at the advanced stages of the polyesterification.

The effects of the ratio of MG:DG are seen in the early period of the reaction in Figure 4. The three-point method was adopted to evaluate the initial rate of the reactions. The results are presented in Table 3. The MG:DG ratio for A-30, A-40 and A-60 was 1.91, 2.66 and 2.65, respectively. The initial reaction rates of A-30, A-40 and A-60 was 6.8169, 12.7860 and 14.3379 mg KOH g$^{-1}$ s$^{-1}$, respectively. It can be seen that, the initial reaction rates for high MG:DG ratio (A-40 and A-60) were significantly higher than the lower MG:DG ratio (A-30). In addition, the initial reaction rate of A-40 was double than A-30. Comparing all ratios, A-40 and A-60 achieved the equilibrium after 1 hr. The DP of the reactions was determined using Equations 1 and 2.

The influences of MG:DG ratio on the DP are also illustrated in Figure 4. As expected, the DP had increased with the reaction propagation. Two separate stages were identified in the DP analysis. The first straight nature of the curve indicates the formation of bonds between PA and primary hydroxyl groups. The rate of the reaction was
substantially influenced by the MG:DG ratio. It can be inferred that high MG:DG ratio is responsible for high rate of reaction. On the other hand, the second stage indicates the reaction between the PA and secondary group of MG. In this stage, a high DP value was observed up to 2 hr of reaction time for the case of A-60. Therefore, A-60 was chosen as the optimal ratio.

**Molecular Weight (M_w) Characterisation**

Table 1 presents the weight molecular weight (M_w) of the alkyd resin at various reaction times. It can be seen that as the reaction preceded the increased M_w of the synthesised alkyd resin (A-30 and A-60). Initially, at the start of the polymerisation reaction, the rate of the polymerisation was low. Therefore, the M_w of the formulated resin was also low and as the rate increased, the M_w of the polymer also increased. Previous researchers whom studied with vegetable oil-based alkyls recorded similar observations. It is noticed that, the M_w of A-60 was higher than A-30 at all time intervals. This phenomenon might be due to that the MG/DG ratio of A-60 (2.65) was higher than A-30 (1.91). It is well known that, MG and DG in the mixture could readily react with phthalic anhydride during polyesterification reaction and DG acted as a chain stopper. The chain length of the alkyd was significantly influenced by the ratio of MG to DG in the mixture, which directly affected the M_w of alkyd. Therefore, the A-60 sample with higher MG:DG ratio possessed higher M_w than A-30 sample.
TABLE 1. MOLECULAR WEIGHT (M_w) OF ALKYD RESIN, A-30 AND A-60 AT VARIOUS INTERVALS TIME

| Time (min) | A-30 (g mol⁻¹) | A-60 (g mol⁻¹) |
|------------|----------------|----------------|
| 0          | 740            | 740            |
| 30         | 1 202          | 1 406          |
| 60         | 1 373          | 1 655          |
| 120        | 1 988          | 2 108          |
| 180        | 2 374          | 2 505          |

FTIR Analysis

Figure 5 shows the FTIR spectra of A-60 and palm oil. The absorbance peak at 3650-3350 cm⁻¹ (Ong et al., 2015c; Khan et al., 2016; Ong et al., 2016c) confirmed the presence of hydroxyl group. The strong absorbance peak in the range of 3050-2780 cm⁻¹ detected the C-H stretching. The stretching vibration of C-O-C and C=O functional group in ester of TG was confirmed by the peak at 1280-1700 cm⁻¹, respectively (Assanvo et al., 2015). The absorption of C-H bending was at 1465-1445 cm⁻¹. The peak at 735 cm⁻¹, detected the unsaturated condition of the fatty acids. A new characteristic peak for the ester functional group appeared and confirmed by the peak at 1255-1225 cm⁻¹. The peak at 750 cm⁻¹, confirmed the C-H bending in the aromatic group. The peak can confirm the incorporation of phthalate group and the polyesterrification.

Pencil Hardness Test

The pencil hardness testing was performed for the measurement of the hardness of the films. The results are presented in Table 2. The analysis showed A-60 film has better hardness than A-30 film, as A-60 film passed pencil category B. This might be due to higher crosslinking in A-60 film compared to A-30 film.

TABLE 2. PENCIL HARDNESS OF A-30 AND A-60 CURED FILM

| Pencil type | A-30 film | A-60 film |
|-------------|-----------|-----------|
| 2B          | Pass      | Pass      |
| B           | Fail      | Pass      |
| HB          | Fail      | Fail      |

Chemical Resistivity

Table 3 presents the performance of chemical resistivity of A-30 and A-60. Results showed that both films were highly resistant to the chemicals (hydrochloric acid and aqueous sodium chloride) and distilled water, but the results were different for the case of NaOH. The resistivity was different for different samples. A-30 film showed poor resistivity to alkali solution, while A-60 film showed comparatively fair resistivity to the same solution. This is because of the hydrolysis process of the ester functional groups present in the alkyds (Essien et al., 2015).

TABLE 3. CHEMICAL RESISTIVITY OF A-30 AND A-60 FILMS

| Solution        | A-30 film | A-60 film |
|-----------------|-----------|-----------|
| Distilled water | Excellent | Excellent |
| 5% of HCl (aq.) | Excellent | Excellent |
| 5% NaOH (aq.)   | Poor      | Fair      |
| 5% NaCl (aq.)   | Excellent | Excellent |

CONCLUSION

The scope of this work is to find the effects of the variation of MG/DG ratio on the properties of palm oil-based polyalkyds. The synthesis process includes alcoholysis followed by polyesterification. Different properties of polyalkyds like $M_w$, DP, structural, hardness and chemical resistivity were evaluated. The FTIR analysis confirmed the presence of ester functional groups in the prepared alkyl resins. It was found that, the reaction time had shortened due to the higher initial rate at higher MG:DG ratio. The initial rate for A-60 (MG:DG=2.65) was two times higher than the A-30 (MG:DG=1.91). In addition, higher MG/DG ratio in the polyesterification reactions produced the alkyl resin with higher $M_w$. Moreover, A-60 film possessed better pencil hardness and chemical resistivity than A-30 film. It can be concluded that a higher ratio of MG:DG resulted in a higher $M_w$ polyalkyds, which can be suitable for coating application.

ACKNOWLEDGEMENT

This work was financially supported by research grant from Universiti Malaysia Pahang, Malaysia (Project No: GRS 130350) and GSAS scholarship from Malaysian Palm Oil Board for which the authors are very grateful.
