Objective: To evaluate the antibacterial effect of Sahara honeys (SHs) against bacterial biofilms formed on urinary catheters in combination with propolis-Sahara honeys (P-SHs).

Methods: Three clinical isolates were subjected to biofilm detection methods. The antibacterial and anti-biofilm activity for SHs and P-SHs were determined using agar well diffusion and the percentage of biofilm inhibition (PBI) methods.

Results: The PBI for Gram-positive bacteria [Staphylococcus aureus (S. aureus)] was in the range of 0%–20%, while PBI for Gram-negative bacteria [Pseudomonas aeruginosa and Escherichia coli (E. coli)] were in range of 17%–57% and 16%–65%, respectively. The highest PBI (65%) was produced by SH2 only on E. coli. In agar well diffusion assay, zones of inhibition ranged from 11–20 mm (S. aureus), 9–19 mm (Pseudomonas aeruginosa) and 11–19 mm (E. coli). The highest inhibition (20 mm) was produced by SH1 only on S. aureus.

Conclusions: SHs and P-SHs applied as a natural agent can be used as a prophylactic agent to prevent the formation of in vitro biofilm.

ABSTRACT

Introduction

A number of previous studies have shown the urinary tract colonization and infection caused by Staphylococcus aureus (S. aureus), Pseudomonas aeruginosa (P. aeruginosa) and Escherichia coli (E. coli) in patients with indwelling urinary catheters[1,2]. Al-Mathkhury et al.[3] demonstrated the Gram-negative opportunistic P. aeruginosa common colonization of urinary catheters and biofilm development on them. Several factors may contribute for the pathogenicity of bacterial biofilm formation, including the production of extracellular compounds (E. coli: flagellum; S. aureus: lipopolysaccharides, exopolysaccharide; P. aeruginosa: flagella and pili), production of resistant “persister cells”, surface adherence and biofilm formation[4-6]. The adhesion of bacteria to a surface depends on various factors (nutrient levels, pH changes, desiccation, ultraviolet radiation and osmotic stress)[7,8]. More recently, some substances showing antibacterial properties, such as nitrous oxide chlorhexidine, nitrofurazone and gentian violet, have been used to modify the surface of urinary catheters[9]. But the biofilms are notoriously difficult to eradicate. In addition to the difficulty of treating biofilms with conventional antibiotics, recently alternative treatments are playing their role in the treatment of biofilms.

The antimicrobial activities of bee products, such as honey and propolis, have been researched over recent years as alternatives for new therapeutic agents for the treatment of bacterial biofilm infections[10,11]. Algerian honey [Sahara honey (SH)] was reported to inhibit the growth of S. aureus, P. aeruginosa and E. coli[12,13],...
Today, no information is available about the effects of SHs on biofilms. Therefore, this study was performed to investigate the role of SHs at different concentrations alone or in combination with propolis-Sahara honeys (P-SHs) on biofilms. We also investigated the effects of P-SHs on biofilms for the first time.

2. Materials and methods

2.1. Honey and propolis samples

The present study was carried out on raw SH of different floral origins, namely, Euphorbe (SH1) (*Euphorbia* spp.) and Sidr honey (SH2). The propolis used in this study was obtained from Southern Algeria.

2.2. Preparation of propolis solutions

The propolis was cold-macerated to make an extract with olive oil (20 g of brute propolis/2 mL of olive oil). The mixture was heated at 50 °C for 15 min before microbiological testing.

2.3. Preparation of honey with olive oil – propolis

The mixture was stirred gently with a spatula until homogeneous gel was formed. The mixture was heated at 50 °C for 15 min. For a microbiological test of a mixture of honey, 20 g of propolis was made, where the honey was added in a concentration of 25%, 50% or 100%.

2.4. Bacterial isolates and growth media

The catheters were removed from patients and then cut under aseptic conditions using a sterile scalpel. The catheter was carefully and aseptically cut. Three discs were placed on the surface of Chapman, MacConkey and King A agar plates. Colony formation was monitored by examining plates after 48 h of incubation.

2.5. Antibacterial susceptibility testing

In this study, two different assays were performed to evaluate the antibacterial potential of the honey samples: agar-well diffusion (AWD) and percentage of biofilm inhibition (PBI).

2.5.1. AWD

Antibacterial studies have been evaluated by the method of AWD by Moussa *et al.*[13]. Briefly, agar plates (90 mm) were containing 20 mL of nutrient agar at 37 °C for 24 h and adjusted by diluting fresh cultures to a turbidity equivalent to 0.5 McFarland scale (approximately $2 \times 10^8$ colony-forming unit/mL). An 8 mm diameter well was cut into the agar and 100 µL of undiluted, and 25% and 50% honey solution (w/v) prepared in sterile distilled water was aliquoted into the well. The controls were set up with equivalent quantities of water. After incubation, the diameters of the inhibition zones were measured.

2.5.2. PBI

The method adopted was described by Akujobi and Njoku with little modification[14]. Briefly, 0.2 mL of 0.5 McFarland standardised culture was added to 4 mL of the test (SHs and P-SHs). Concentration in a test tube while inoculation of 4 mL of nutrient broth with 0.2 mL of the cell suspension was served as the control. The optical density (OD) was determined in a spectrophotometer at 620 nm prior to incubation (T0) and recorded after the cultures were incubated for 24 h in the dark at 37 °C. The OD was determined at T0 and again after 24 h of incubation at 620 nm. The OD for each replicate at T0 was subtracted from the OD for each replicate after 24 h of incubation. The PBI was calculated using the following formula:

\[
PBI\% = \left(\frac{OD_{control} - OD_{experimental}}{OD_{control}}\right) \times 100
\]

2.5.3. Biofilm response to SHs and P-SHs

The bacterial anti-adhesive activity of the SHs and P-SHs against bacterial biofilms was qualitatively evaluated by the following method (Table 1).

| Tube | Experiment I Treatment after 24 h | Experiment II Incubation |
|------|-----------------------------------|--------------------------|
| Tube 1 | Nutrient broth + catheter | Nutrient broth + catheter bacterial (single and mixed) | 48 h |
| Tube 2 | Nutrient broth + SHs (25%, 50% and 100%) + catheter | Nutrient broth + catheter bacterial (single and mixed) | 48 h |
| Tube 3 | Nutrient broth + Propolis + catheter | Nutrient broth + catheter bacterial (single and mixed) | 48 h |
| Tube 4 | Nutrient broth + P-SHs (25%, 50% and 100%) + catheter | Nutrient broth + catheter bacterial (single and mixed) | 48 h |

Tube 1: Sterile catheter segments were immersed in 5 mL sterile culture tubes nutrient broth and incubated at 37 °C for 24 h (Experiment I), and after 24 h, the tubes were inoculated with 100 µL of bacterial inoculum ($2 \times 10^6$ cells/mL) and incubated at 37 °C for 48 h (Experiment II); Tube 2: Sterile catheter segments were immersed in 5 mL sterile culture tubes nutrient broth + SHs (25%, 50% and 100%) and incubated at 37 °C for 24 h (Experiment I), and after 24 h, the tubes were inoculated with 100 µL of bacterial inoculum ($2 \times 10^6$ cells/mL) and incubated at 37 °C for 48 h (Experiment II); Tube 3: Sterile catheter segments were immersed in 5 mL sterile culture tubes nutrient broth + propolis and incubated at 37 °C for 24 h (Experiment I), and after 24 h, the tubes were inoculated with 100 µL of bacterial inoculum ($2 \times 10^6$ cells/mL) and incubated at 37 °C for 48 h (Experiment II); Tube 4: Sterile catheter segments were immersed in 5 mL sterile culture tubes nutrient broth + P-SHs (25%, 50% and 100%) and incubated at 37 °C for 24 h (Experiment I), and after 24 h, the tubes were inoculated with 100 µL of bacterial inoculum ($2 \times 10^6$ cells/mL) and incubated at 37 °C for 48 h (Experiment II).
3. Results

3.1. Antibacterial activity

Figures 1–3 show the PBI data for the bee product tested against Gram-negative and Gram-positive bacteria. PBI for Gram-positive bacteria (S. aureus) were in the range of 0%–20%, while they were 17%–57% and 16%–65% for Gram-negative bacteria P. aeruginosa and E. coli, respectively. The highest PBI (65%) was produced by SH2 only on E. coli.

In AWD assays, zones of inhibition ranged from 11–20 mm S. aureus, 12–16 mm P. aeruginosa and 11–19 mm E. coli. The highest inhibition (20 mm) was produced by SH1 only on S. aureus (Table 2).

The results of the synergistic effect between SHs and P-SHs are given in Figures 4–6, respectively. In combination with P-SHs, the PBI ranged from 16% to 79% against S. aureus, 31% to 87% against P. aeruginosa and 22% to 67% against E. coli, respectively. The highest PBI (79%) was produced by SH2 in combination with propolis on S. aureus (Figure 4).

In AWD assays, zones of inhibition ranged from 11 to 20 mm against S. aureus, 9–19 mm and 11–19 mm against P. aeruginosa and E. coli, respectively. The highest concentration required was 100% to simultaneously inhibit all bacteria tested (Table 2).

Table 2

Mean zones of inhibition values of the honey samples against bacterial tested determined by AWD.

| Concentrations | S. aureus | P. aeruginosa | E. coli |
|----------------|-----------|---------------|---------|
|                | 100%      | 50%           | 25%     | 100% | 50% | 25% |
| SH1            | 20        | 15            | 13      | 16   | 14 | 13 |
| SH2            | 18        | 13            | 11      | 15   | 14 | 12 |
| P-SH1          | 17        | 12            | 11      | 17   | 11 | 9  |
| P-SH2          | 18        | 13            | 11      | 19   | 15 | 12 |
| Negative control | -        | -             | -       | -    | -  | -  |

3.2. Effect of SHs and P-SHs on biofilm-forming bacterial growth

In a second series of experiments, the disruption of preformed biofilms (48-h growth in the absence of SHs and P-SHs) by addition of SHs and P-SHs at various concentrations for 48 h. The SHs and P-SHs inhibited biofilm formation on catheters (Table 3). This suggested that SHs, propolis and P-SHs have a better ability to prevent biofilm formation.
4. Discussion

Biofilm-producing bacteria are intrinsically resistant to antimicrobial agents, which is a main cause of the pathogenesis of catheter infection[15,16], and the susceptibility of bacteria biofilms to the current therapeutic agents remains low. Currently, researches are focused on the development of anti-biofilm agents that are nontoxic, as it is believed that such molecules will not lead to future drug resistance[17]. Researches aiming at new anti-biofilm originating mainly from bee products have long been revered for their healing. The anti-biofilm properties of bee products as a natural antibiotic agent have been extensively studied. Strong antibacterial activities of propolis and honey against both Gram-positive and Gram-negative bacteria have been reported[11,18]. In addition, several investigators examined the effects of honey and propolis on biofilms. Campeau and Patel[10] reported that Manuka honey has a synergistic interaction with vancomycin against S. aureus biofilms and an additive interaction with gentamicin against P. aeruginosa biofilms. In addition, Jenkins and Cooper[19] reported that Manuka honey-exposed planktonic S. aureus cells were enlarged and had more septa. Cooper et al.[20] reported that Manuka honey at concentrations below 10% (w/v) promoted the growth of established biofilms of S. aureus. Also, Alandejani et al.[21] studied S. aureus and P. aeruginosa biofilms but only evaluated 50% Manuka and Sidr honey. The therapeutic effects of the propolis and honey are well known. Several aspects of this use indicate that they also have functions such as antibacterial and anti-biofilm proprieties. Biological activities of honey and propolis are mainly attributed to the phenolic compounds such as flavonoids[22]. It has recently been reported that several flavonoids reduced biofilm formation in Vibrio harveyi and E. coli O157:H7[23]. Also, various honeys were investigated for the presence of nitrite/nitrate, the stable nitric oxide metabolites[24]. Barraud et al.[25] observed a decrease in biofilm biomass and an increase in planktonic biomass at low concentrations of nitric oxide donors. In addition, honey is a saturated or supersaturated solution of carbohydrates of glucose and fructose[26]. Previous work by Dusane et al.[27] has reported that the lauroyl glucose after 48 h of incubation with P. aeruginosa and Pseudomonas aureofaciens resulted in 51% and 57% of the disruption of preformed biofilms, respectively. Carvacrol (thymol isomer) is present in the essential oil of Algerian propolis (4.47%)[28]. Antibacterial effect of carvacrol and its isomer thymol against E. coli, P. aeruginosa and Enterococcus faecalis have been proved[29]. Several studies have examined the effect of various types of antimicrobial treatment in controlling biofilm formation on these devices [central venous catheters, mechanical heart valves and urinary (Foley) catheters][30]. To our knowledge, this is the first time these novel anti-biofilm agents (SHs and P-SHs) are reported on the tested organisms. SHs, propolis and P-SHs exhibited excellent antibacterial and anti-adhesive properties against S. aureus, P. aeruginosa and E. coli, which was evidenced in our adhesion based assays.

Conflict of interest statement

We declare that we have no conflict of interest.
