UNIQUENESS FOR SOLUTIONS OF THE
SCHRÖDINGER EQUATION ON TREES

AINGERU FERNÁNDEZ-BERTOLIN AND PHILIPPE JAMING

ABSTRACT. We prove that if a solution of the time-dependent Schrödinger equation on an homogeneous tree with bounded potential decays fast at two distinct times then the solution is trivial. For the free Schrödinger operator, we use the spectral theory of the Laplacian and complex analysis and obtain a characterization of the initial conditions that lead to a sharp decay at any time. We then use the recent spectral decomposition of the Schrödinger operator with compactly supported potential due to Colin de Verdière and Truc to extend our results in the presence of such potentials. Finally, we use real variable methods first introduced by Escauriaza, Kenig, Ponce and Vega to establish a general sharp result in the case of bounded potentials.

1. Introduction

The aim of the present paper is to study uniqueness results for Schrödinger equations with bounded potentials on homogeneous trees. These results can be seen as a version for homogeneous trees of a dynamical interpretation of the Hardy Uncertainty Principle.

The Schrödinger equation $i\partial_t u = \Delta u + Vu$ has been extensively studied by mathematicians and physicists. Those studies take place in various underlying spaces, both continuous ($\mathbb{R}^d$, manifolds,...) and discrete. In the discrete setting, on $\mathbb{Z}^d$, when the potential is chosen randomly on each $k \in \mathbb{Z}^d$, this corresponds to the celebrated Anderson model introduced by Anderson in [An] in order to describe the behavior of a quantum particle in disordered medium. In this paper, we will be dealing with the Schrödinger equation when the underlying space is an homogeneous tree (also known as a Bethe lattice in the physics community). The corresponding Anderson model has been introduced very early on by Abou-Chacra, Thouless and Anderson [ACTA]. This model allows to obtain closed form formulas for some models which

2010 Mathematics Subject Classification. 05C05;31C20;39A12;81Q10.
Key words and phrases. Schrödinger equation, Bethe lattice, homogeneous trees, Uncertainty Principle.
is one of the reasons why it has also been extensively studied. (see e.g. the books [CL, PF, St] and the surveys [Ab, Wa] for more on the subject, for the tree case, one may further refer to [HES] and its extensive bibliography). One of the most studied properties here is the so-called Anderson Localization Property, that is, the localization of the spectrum of the Schrödinger operator. Our aim here is of a somewhat different nature as we are interested in localization properties of solutions of the Schrödinger equation. More precisely, we will prove that solutions of the Schrödinger equation \( i\partial_t u = \Delta u + Vu \) on an homogeneous tree can not be too sharply localized at 2 different times when the potential \( V \) is bounded. In our study, the potential is not random but the results directly apply to potentials that are chosen randomly on each vertex of the tree with bounded random variables (e.g. uniformly in some interval or Bernoulli random variable so that the results apply in the so-called Anderson-Bernoulli model). Our results may thus be seen as a dynamical version of the Uncertainty Principle. Before outlining our results more precisely, let us first explain what we mean by “localizing” and further explain our motivations in this paper.

Let us start by recalling Hardy’s uncertainty principle [Ha] on the real line: assume \( f \in L^2(\mathbb{R}) \) satisfies a decrease property like

\[
|f(x)| \leq Ce^{-x^2/\beta^2}, \quad |\hat{f}(\xi)| \leq Ce^{-4\xi^2/\alpha^2}.
\]

Then, if \( \alpha\beta < 4 \), \( f \equiv 0 \) while, in the end-point case, \( \frac{1}{\alpha\beta} = \frac{1}{4} \), \( f = Ce^{-x^2/\beta^2} \). In other words, a function and its Fourier transform can not both be localized below two sharply localized Gaussians.

Numerous authors have extended this result to higher dimensions, replacing the point-wise estimate (1.1) by integral or even distributional conditions (see e.g. the works of Hörmander, Bonami, Demange and the second author [Ho, BDJ, BD, De]) and also replacing the underlying space \( \mathbb{R}^d \) by various Lie groups (as can be found for instance in the work of Baklouti, Kaniuth, Sitaram, Sundari, Thangavelu,... including [BK1, BK2, SST, Th1, Th2]). The survey [FS] and the books [HJ, Th3] may be taken as a starting point to further investigate the subject. Most of this work requires either complex analysis or a reduction to a real variable setting in which complex variable tools are available. A first difficulty appears here as the decrease in the space variable and in the Fourier variable can no longer be measured in the same way. This problem becomes even more striking in the discrete setting. For instance, for functions on \( \mathbb{Z} \), the Fourier transform is a periodic function, so that there is no decrease at infinity.
To overcome this, one way is to consider a dynamical interpretation of the uncertainty principle. To explain what we mean by this, let us go back to the real line. Recall that the solution of the free Schrödinger equation $i \partial_t u = \Delta u$, $u(0, x) = u_0(x)$ is given by the following representation formula:

$$u(x, t) = (4\pi it)^{-n/2} \int_{\mathbb{R}^n} e^{-i(x-y)^2/4t} u_0(y) \, dy = (2\pi it)^{-n/2} e^{-|x|^2/4t} \hat{u}_0 \left( \frac{-x}{2t} \right).$$

Hence, the solution at a fixed time has, roughly speaking, the same size as the Fourier transform of the initial data, and we can translate decay properties of $u_0$ and $\hat{u}_0$ into decay properties of $u_0$ and $u(x, T)$ for a fixed time $T$, to have

$$|u_0(x)| \leq C e^{-x^2/\beta^2}, \quad |u(x, T)| \leq C e^{-x^2/\alpha^2}, \quad \frac{T}{\alpha \beta} > \frac{1}{4} \implies u \equiv 0$$

and, if $\frac{T}{\alpha \beta} = \frac{1}{4}$, $u_0(x) = C e^{-x^2 (1/\beta^2 + i/4T)}$.

This point of view has been used by Chanillo [Ch] to prove a dynamical uncertainty principle on complex semi-simple Lie groups by reducing the problem to Hardy’s Uncertainty Principle on the real line. At the same time, Escauriaza, Kenig, Ponce and Vega started a series of papers [EKPV1, EKPV2, EKPV3] were they provide the first proof of the Hardy Uncertainty Principle in its dynamical version in the presence of a potential, using real calculus. Their motivation is to consider solutions of general linear Schrödinger equations $i \partial_t u = \Delta u + Vu$, only assuming size conditions for the space and time-dependent potential $V$. The robustness of their methods allows to extend their results to different settings, such as for covariant Schrödinger evolutions by Barceló, Cassano, Fanelli, Gutiérrez, Ruiz, Vilela [BFGRV, CF], or heat evolutions [EKPV4] but also to other underlying spaces, see e.g. the work of Ben Saïd, Dogga, Ludwig, Müller, Pasquale, Sundari, Thangavelu [PS, BSTD, LuMu].

More recently, independently in [FB, FBV, JLMP], together with Lyubarskii, Malinnikova, Perfekt and Vega, we began to extend the previous results to the discrete setting, understanding the Laplace operator as a finite-difference operator, acting on complex-valued functions $f : \mathbb{Z} \to \mathbb{C}$,

$$\Delta_d f(n) := f(n+1) + f(n-1) - 2f(n).$$
For the free evolution, or for the linear evolution with a bounded time-independent potential, as shown in [LyMa], one can use complex analysis tools, more precisely refined versions of the Phragmén-Lindelöf principle, to give a discrete version of the Hardy Uncertainty Principle. As in the continuous case, the critical decay is given by the discrete heat kernel, given in terms of modified Bessel functions. However, this similarity leads also to the main difference between both settings, because the critical decay is not Gaussian. More precisely, it is shown in [JLMP] that for $0 < \alpha < 1$ and $u$ a $C^1([0,1],\ell^2(\mathbb{Z}))$-solution of $\partial_t u = i\Delta_d u$ (a so-called strong solution), if $u$ satisfies the estimate

\begin{equation}
|u(n,0)| + |u(n,1)| \leq CI_n(\alpha) \sim \frac{C}{\sqrt{|n|}} \left( \frac{e\alpha}{2|n|} \right)^{|n|}, \ n \in \mathbb{Z} \setminus \{0\},
\end{equation}

then $u \equiv 0$. In the end-point case, $\alpha = 1$, $u(n,t) = \gamma i^{-n} e^{-2it} J_n(1-2t)$, where $\gamma$ is a constant and $J_n$ is the Bessel function. Note that classical estimates of Bessel functions show that, for any $\gamma > 0$, there is a $C > 0$ such that this solution indeed satisfies (1.2). This argument is also extended to other type of problems, as shown by Alvarez-Romero and Teschl [ART] for Jacobi operators.

In the case of linear Schrödinger equations, one can give a dynamical version of the Hardy Uncertainty Principle, only assuming that the potential is bounded, which makes another difference with the continuous case, since in the continuous case, all results in [EKPV1, EKPV2, EKPV3] require to have some decay in the potential, and the result is still open for bounded potentials. To be more precise, the first author and Vega [FBV] showed that if $u$ is a strong solution of $\partial_t u = i(\Delta_d u + V u)$ on $\mathbb{Z}$ (with $V = V(n,t)$ bounded) and if $u$ satisfies the decay condition

\begin{equation}
\sum_{n \in \mathbb{Z}} e^{2\mu(n+1) \log(|n|+1)}(|u(n,0)|^2 + |u(n,1)|^2) < \infty
\end{equation}

for some $\mu > 1$, then $u = 0$. In view of the free case, as $u(n,t) = \gamma i^{-n} e^{-2it} J_n(1-2t)$ is a solution of the free Schrödinger equation and it satisfies (1.3) with $\mu = 1 - \epsilon$, $\forall \epsilon > 0$ (as one can deduce from (1.2)), the condition $\mu > 1$ is optimal. It is worth to mention that $\mu = 1$ gives the leading term in the asymptotic expression for $I_n(\alpha)$ in (1.2). Note also that [JLMP, FB] both contain similar results but only in non-optimal cases $\mu > \mu_0 > 1$. A higher dimensional version of this result can be found in [FBV], although the rate of decay $\mu$ obtained there depends on the dimension and the sharp result is still open. The key tool here is to establish Carleman type estimates, that is, a weighted inequality of the form $C_w \|wu\|_{L^2(\mathbb{Z}^d)} \leq \|w(i\partial_t + \Delta_d)u\|_{L^2(\mathbb{Z}^d)}$ for an appropriate
weight \( w \) and a constant \( C_w \) depending on this weight. We refer e.g. to [LR] for more on Carleman estimates and their use mainly in the continuous setting.

Therefore the results in [FBV, JLMP, LyMa] are based on two different approaches. For the linear evolution with time-independent potential with bounded support one uses complex analysis, while in the presence of a time-dependent bounded potential the Phragmén-Lindelöf principle is not available and one replace this by a suitable Carleman inequality (using real variable methods instead of complex analysis).

In this paper we extend both approaches to homogeneous trees of degree \( q+1 \) (Bethe lattices), which we denote by \( T_q \). This is a connected graph with no loops, rooted in a point denoted by \( o \), where every vertex is adjacent to \( q + 1 \) other vertices, a relation denoted by \( y \sim x \). Thus, one can see \( T_q \) as a natural extension of the line \( \mathbb{Z} \), which can be seen as an homogeneous tree of degree 2. One may then ask whether the behavior for solutions of Schrödinger evolutions is similar on \( \mathbb{Z} \) and on \( T_q \). As in the line \( \mathbb{Z} \), we understand the Laplacian as the combinatorial Laplacian, that is a finite-difference operator \( \mathcal{L} \) only taking into account interactions between nearest-neighbors (see Section 2 for a precise definition).

It is our aim here to contribute to the understanding of the behavior of solutions of Schrödinger equations on trees (see e.g. the recent papers by Anantharaman, Colin de Verdière, Eddine, Sabri, Truc [AS, Ed, CdVT] for other directions) as well as to establish Uncertainty Principles on trees (so far, we are only aware of one article by Astengo [As] dealing with that issue). Finally, homogeneous trees can also be seen as a discrete analogues of hyperbolic spaces and more precisely 0-hyperbolic spaces in the sense of Gromov. The Schrödinger operator on real hyperbolic spaces has attracted a lot of attention recently (see e.g. the work of Anker, Banica, Carles, Ionescu, Pierfelice, Staffilani, [AP, Ba, BCS, IS]) and we hope that this work may also lead to new insight in that setting.

We are now in position to describe our results. First, since the spectral theory of the Laplacian on homogeneous trees is known (see Cowling and Setti [CS]), we have all the ingredients to give a dynamic interpretation of the Hardy Uncertainty Principle on \( T_q \) when there is no potential:
Theorem A. There exists a function $U_q$ on $T_q$ such that, if $u$ is a strong solution of the equation
\[ i\partial_t u(x, t) = \mathcal{L}u(x, t) = u(x, t) - \frac{1}{q+1} \sum_{y \sim x} u(y, t), \quad x \in T_q \]
with $u(x, 0) = u_0(x)$ and if at times $t_0 = 0$ and $t_1 = 1$, there is a constant $\kappa > 0$ such that, for $x \neq o$
\[
|u(x, t)| \leq \kappa \left( \frac{e}{2(q+1)|x|} \right)^{|x|}
\]
then $u_0 = \gamma U_q$ for some $\gamma \in \mathbb{C}$ with $|\gamma| \leq \kappa$.

The function $U_q$ is explicitly given by an integral formula, see below, and this function has exactly the rate of decay given by (1.4). In order to compare our results with the case of $\mathbb{Z}$, let us rewrite (1.4) as
\[
|u(x, t)| \leq \kappa |x|^{-1/2} e^{\left( \frac{1 - \ln 2(q+1)}{2q+1} \right) |x|} e^{-|x| \ln |x|}.
\]
We thus see that the main term $e^{-|x| \ln |x|}$ does not depend on the tree and is the same as for $\mathbb{Z}$ and that the dependence on the degree of the tree is rather mild. It is somewhat unexpected that the behavior is the same in both cases as the tree is the Cayley-graph of the free group which is non-amenable and has exponential growth while $\mathbb{Z}$ is amenable and has polynomial growth.

Further, as an immediate corollary, we obtain

Corollary B. Let $\mu > 1$. If $u$ is a strong solution of the equation
\[ i\partial_t u(x, t) = \mathcal{L}u(x, t) = u(x, t) - \frac{1}{q+1} \sum_{y \sim x} u(y, t), \quad x \in T_q \]
with $u(x, 0) = u_0(x)$ and if at times $t_0 = 0$ and $t_1 = 1$,
\[
\sum_{x \in T_q} e^{2\mu |x| \log(|x|+1)} (|u(x, 0)|^2 + |u(x, 1)|^2) < +\infty
\]
then $u \equiv 0$.

Our second aim is to show that this corollary stays true for the Schrödinger equation in presence of a potential.

More precisely, we consider two cases. First, we consider solutions of
\[ i\partial_t u(x, t) = \mathcal{L}u(x, t) + \mathcal{V}u(x, t) \]
where $\mathcal{V}$ is a finitely supported hermitian perturbation independent of time
\[ \mathcal{V}u(x, t) = \sum_{y \in T_q} v(x, y) u(y, t) \]
with \( v(y, x) = v(x, y) \) and the support of \( v \) is finite. In this case, we have been able to exploit the spectral theory of the operator \( \mathcal{L} + V \) developed by Colin de Verdière and Truc in [CdVT]. This allows to extend the previous theorem to compactly supported perturbations of the free Schrödinger equation, see Theorem 4.1 below for a detailed statement. The spectral theory in [CdVT] is also extended to graphs isomorphic to a homogeneous tree at infinity. These graphs, outside a finite sub-graph, look like \( T_q \). Although we do not include the details, it can be checked that the same results are valid for this type of operators. This can be seen as an extension of the result by Alvarez-Romero [AR], where the case of a finite number of threads (lines) attached to a finite graph is studied.

The next part of the paper is devoted to the study of the simplified problem \( i\partial_t u(x) = \mathcal{L}u(x) + V(x, t)u(x) \), with a bounded time-dependent potential \( V \), using real variable calculus. Compared to the previous case, this corresponds to \( v(x, y, t) = V(x, t) \) if \( y = x \) and \( v(x, y, t) = 0 \) otherwise, i.e. now \( v \) is supported on the diagonal but is no longer assumed to be finitely supported nor time-independent.

This approach combines the main techniques of [FBV, JLMP], to prove first that a fast decaying solution at two different times preserves this decay at any interior time, and, later, via a Carleman estimate with Gaussian weight, we give a lower bound for the \( \ell^2 \)-norm of the solution in a region far from the origin (see Theorem 5.6 below). A combination of these two facts leads then to:

**Theorem C** (Uniqueness result). Let \( u \in C^1([0, 1] : \ell^2(T_q)) \) be a solution of \( i\partial_t u(x) = \mathcal{L}u(x) + V(x, t)u(x) \) with \( V \) a bounded potential. If for \( \mu > 1 \)

\[
\sum_{x \in T_q} e^{2\mu|x| \log(|x|+1)} \left(|u(x, 0)|^2 + |u(x, 1)|^2\right) < +\infty,
\]

then \( u \equiv 0 \).

This shows that Corollary B is also valid in the presence of a bounded potential, in particular, the condition \( \mu > 1 \) is essentially sharp up to the end-point \( \mu = 1 \) which is open except for compactly supported potentials. This result is exactly the same as in the case of \( \mathbb{Z} \), [FBV]. This is no longer surprising in view of Theorem A and Corollary B as the influence of the tree on the optimal decay is very mild. However, one may ask if this result is true for any infinite graph, or if it can be extended to large classes of graphs. We provide some examples of infinite graphs for which the behavior of the solutions is different.
The remaining of the paper is organized as follows: in Section 2 we introduce some notation and preliminaries from the theory of entire functions as well as a summary of the spectral theory of the adjacency matrix on $\mathbb{T}_q$. These notions can be found in [CdVT, Le], but we include them here to clarify our presentation. Section 3 studies the free Schrödinger equation and includes the proof of Theorem A. In Section 4 we use again complex analytic tools to extend Theorem A and cover the case of compactly supported potentials. Section 5 covers the real variable approach, proving Theorem C via a Carleman inequality and logarithmic convexity of $\ell^2$ weighted norms. We conclude in Section 6 with some considerations on other graphs.

2. Notation and preliminaries

2.1. Entire functions of exponential type. As in [JLMP], we will use methods from complex analysis. For the reader’s convenience, we begin by briefly outlining some definitions and facts on entire functions of exponential type that we need. Details can be found in [Le] (see in particular Lectures 8 and 9). Recall that an entire function $f$ is said to be of exponential type if for some $k > 0$

\begin{equation}
|f(z)| \leq C \exp(k|z|).
\end{equation}

In this case the type of an entire function $f$ is defined by

\begin{equation}
\sigma = \limsup_{r \to \infty} \frac{\log \max\{|f(re^{i\phi})|; \phi \in [0, 2\pi]\}}{r} < \infty.
\end{equation}

In particular, an entire function $f$ is of zero exponential type if for any $k > 0$ there exists $C = C(k)$ such that (2.6) holds.

Let $f(z)$ be an entire function of exponential type, $f(z) = \sum_{n=0}^{\infty} c_n z^n$. Then the type of $f$ can be expressed in terms of its Taylor coefficients as

\begin{equation}
\limsup_{n \to \infty} n|c_n|^{1/n} = e\sigma.
\end{equation}

The growth of a function $f$ of exponential type along different directions is described by the indicator function

\[ h_f(\varphi) = \limsup_{r \to \infty} \frac{\log |f(re^{i\varphi})|}{r}. \]

This function is the support function of some convex compact set $I_f \subset \mathbb{C}$ which is called the indicator diagram of $f$:

\[ h_f(\varphi) = \sup\{\Re(ae^{-i\varphi}), a \in I_f\}. \]
In particular

\begin{equation}
(2.9) \quad h_f(\varphi) + h_f(\pi + \varphi) \geq 0.
\end{equation}

For example the indicator function of \( e^{az} \) for \( a \in \mathbb{C} \) is \( h(\varphi) = \Re(ae^{i\varphi}) \) and its indicator diagram consists of a single point, \( \hat{a} \).

Clearly, \( h_{fg}(\varphi) \leq h_f(\varphi) + h_g(\varphi) \), implying that

\[ I_{fg} \subset I_f + I_g := \{ z = z_1 + z_2 : z_1 \in I_f, z_2 \in I_g \}. \]

2.2. Trees. Throughout this paper, \( q \) will be an integer, \( q \geq 2 \). We will denote by \( T = T_q \) the homogeneous tree of degree \( q + 1 \). This means that the tree is formed by a connected graph with no loops where every vertex is adjacent to \( q + 1 \) other vertices, relation denoted by \( y \sim x \).

A geodesic path (resp. geodesic ray, infinite geodesic) in \( T \) is a finite (resp. one-sided infinite, resp. doubly infinite) sequence \( (x_n) \) such that two consecutive terms are adjacent, \( x_n \sim x_{n-1} \) and that does not turn back \( x_{n+1} \neq x_{n-1} \). We can then define the distance \( d(x, y) \) as the number of edges in the (unique) geodesic path which joins \( x \) and \( y \). In particular, in a geodesic, \( d(x_n, x_m) = |n - m| \).

Moreover, we fix a vertex of the tree \( T \) to be the root \( o \) and write \( |x| = d(x, o) \). For an integer \( \ell \geq 0 \), we denote by \( S_\ell = \{ x \in T : |x| = \ell \} \). The boundary \( \partial T \) of \( T \) is defined as the set of infinite paths starting at the root \( o \). Then, we define, for a point \( x \in T \) and \( w \in \partial T \), the confluence point of \( x \) and \( w \), denoted by \( x \wedge w \), as the last point lying on \( w \) in the geodesic path joining \( o \) and \( x \). Attached to this confluence point we define the Busemann function \( h_w \) and the Horocycles \( H^w_k \), \( k \in \mathbb{Z} \) by

\[ h_w(x) = |x| - 2|x \wedge w| \quad \text{and} \quad H^w_k = \{ x \in T : h_w(x) = k \}. \]

We call \( k \) the height of the horocycle \( H^w_k \). Every horocycle is infinite and every \( x \in H^w_k \) has one neighbor \( x^- \in H^w_{k-1} \) (its predecessor) and \( q \) neighbors in \( H^w_{k+1} \) (its successors). We will also need to distinguish between the neighbors and double neighbors of a vertex of the tree in the following way: for \( x \in T \) with \( |x| = n \) we set

- \( x_f = \{ y \in T : |y| = n + 1 \} \) and, if \( x \neq o \), \( x_p \) to be the unique \( y \in T \) such that \( y \sim x \) and \( |y| = n - 1 \). Note that \( |o_f| = q + 1 \) and, if \( x \neq o \), \( |x_f| = q \).

- \( x_{ff} = \{ y \in T : |y| = n + 2, \ y_p \in x_f \} \) so that \( |o_{ff}| = q(q + 1) \) and, if \( x \neq o \), \( |x_{ff}| = q^2 \).

- If \( |x| \geq 2 \), \( x_{pp} = (x_p)_p \).

- If \( x \neq o \), \( x_{pf} = (x_p)_f \setminus \{ x \} \) so that \( |y| = |x| \) if \( y \in x_{pf} \). Note that if \( |x| = 1 \), \( |x_{pf}| = q \) while otherwise \( |x_{pf}| = q - 1 \).
In other words, $x_f$ is the set of followers (daughters) of $x$, $x_p$ the predecessor (mother) of $x$, $x_{pp}$ is the grand-mother of $x$, $x_{ff}$ the set of grand-daughters of $x$, $x_{pf}$ the set of sisters of $x$.

Note that, for any function $\varphi$ on $T$, and any $n \geq 1$,

$$
\sum_{|x|=n} \sum_{z \in x_{pf}} \varphi(z) = \begin{cases} 
q \sum_{|x|=1} \varphi(x) & \text{if } n = 1 \\
(q-1) \sum_{|x|=n} \varphi(x) & \text{if } n \geq 2
\end{cases}.
$$

Now let $\psi_{\ell,k} = |S_\ell \cap H_k^w|$ be the number of elements in an horocycle $H_k$ that are of length $\ell$. When $k \geq 0$,

$$
\psi_{\ell,k} = \begin{cases} 
q^k & \text{if } \ell = k \\
(q-1)q^{k+p-1} & \text{if } \ell = k + 2p, \ p \geq 1 \\
0 & \text{otherwise}
\end{cases}
$$

and for $k \geq 1$,

$$
\psi_{\ell,-k} = \begin{cases} 
1 & \text{if } \ell = k \\
(q-1)q^{p-1} & \text{if } \ell = k + 2p, \ p \geq 1 \\
0 & \text{otherwise}
\end{cases}
$$

Figure 1. The tree $T_2$ and horocycles.

The so called Helgason-Fourier transform (see e.g. [CS]) of a function $f$ on the tree is defined by the formula

$$
\mathcal{F}_T[f](s, w) := \sum_{x \in T} f(x) q^{-\frac{1}{2} + is} h_w(x), \quad s \in \mathbb{T}, \ w \in \partial T,
$$

where $T = \mathbb{R}/\tau \mathbb{Z}$, usually identified with the interval $[-\tau/2, \tau/2)$, with $\tau = 2\pi/\log q$. 
Moreover, the following inversion formula holds,

\[(2.11) \quad f(x) = \int_T \int_{\partial T} q^{-(1/2-is)b_{hw}(x)} F_T[f](s, w) \, d\nu(w) \, d\mu(s), \quad x \in T. \]

We refer to [CS] for the exact definitions of the measures \(\nu\) and \(\mu\).

Finally, we consider the adjacency operator \(A_0\) and the Laplace operator \(L\) on \(T\): for \(u\) a function on \(T\),

\[A_0 u(x) = \sum_{y \sim x} u(y)\]

and

\[L u(x) = \left( I - \frac{1}{q+1} A_0 \right) u(x) = u(x) - \frac{1}{q+1} \sum_{y \sim x} u(y) = \frac{1}{q+1} \sum_{y \sim x} (u(x) - u(y)).\]

We will denote by \(\| \cdot \|_2\) the \(\ell^2(T)\)-norm: if \(u : T \to \mathbb{C}\),

\[\|u\|_2^2 = \sum_{x \in T} |u(x)|^2\]

and by \(\| \cdot \|_{L^2_{x,t}}\) the \(L^2_{x,t}\ell^2\)-norm: if \(u : [0, 1] \times T \to \mathbb{C}\),

\[\|u\|_{L^2_{x,t}} = \int_0^1 \sum_{x \in T} |u(t, x)|^2 \, dt.\]

3. Schrödinger equation on the tree

We want to study uniqueness properties of solutions of the Schrödinger equation \(i\partial_t u = Lu\) assuming that they have fast decay at two different times. Adapting the method developed in [JLMP] in the case of the line \(\mathbb{Z}\) to the tree, our main result in this Section is Theorem A from the introduction, in a slightly more precise form:

**Theorem 3.1.**

Assume that \(u\) is a strong solution of the equation

\[(3.12) \quad i\partial_t u(x, t) = Lu(x, t) = u(x, t) - \frac{1}{q+1} \sum_{y \sim x} u(y, t), \quad x \in T\]

with \(u(x, 0) = u_0(x)\). Assume that there is a constant \(\kappa > 0\) such that, at times \(t_0 = 0\) and \(t_1 = 1\), for \(x \neq o\)

\[(3.13) \quad |u(x, t_i)| \leq \frac{\kappa}{\sqrt{|x|}} \left( \frac{e}{2(q+1)|x|} \right)^{|x|}.\]
Then there exists a constant \( C \) such that \( u_0 \) is the function that only depends on \(|x|\) given by the integral representation formula

\[
u_0(x) = \frac{C}{q^{-|x|/2}} \int_0^\pi \exp \left(-i \frac{q^{1/2}}{q + 1} \cos(z)\right) \varphi_{|x|}(z) \sin(z) \, dz
\]

where

\[
\varphi_j(z) = \frac{q^{1/2} \sin(z(j + 1)) - q^{-1/2} \sin(z(j - 1))}{q + q^{-1} - 2 \cos(2z)}
\]

Remark 3.2. A change of variable allows us to write \( u_0 \) as

\[
u(|x|, 0) = \frac{C}{q^{-|x|/2}} \mathcal{F}[\psi_{|x|}](\frac{q^{1/2}}{q + 1})
\]

where \( \mathcal{F} \) is the Fourier transform on \( \mathbb{R} \) and

\[
\psi_j(s) = \frac{q^{1/2} \sin((j + 1) \arccos s) - q^{-1/2} \sin((j - 1) \arccos s)}{q + q^{-1} + 1 - 2s^2}
\]

on \((-1, 1)\) and \( \psi_j = 0 \) on \( \mathbb{R} \setminus (-1, 1) \).

Proof. Let us fix a geodesic ray \( w = oy_1y_2 \ldots \). Let \( k \in \mathbb{Z} \). As we already noticed, if \( x \in \mathcal{H}_w^w \), it has exactly one predecessor in \( \mathcal{H}_{k-1}^w \) and \( q \) successors in \( \mathcal{H}_{k+1}^w \). Therefore,

\[
\mathcal{L} \left(q^{-(1/2+is)h_w(x)}\right) = \left(1 - \frac{q^{1/2+is}}{q + 1} - q \frac{q^{-1/2-is}}{q + 1}\right) q^{-(1/2+is)h_w(x)}.
\]

For a solution \( u \) of (3.12), we consider the Fourier-Helgason transform \( \tilde{u}(s, w, t) = \mathcal{F}_T[u(\cdot, t)](s, w) \), whose evolution is given by

\[
i \partial_t \tilde{u} = \left(1 - \frac{q^{1/2}}{q + 1}(q^{is} + q^{-is})\right) \tilde{u}.
\]

Hence, if we set \( \sigma = \frac{q^{1/2}}{2(q+1)} \),

\[3.14\]

\[
\tilde{u}(s, w, t) = e^{-i\left(1-2\sigma(q^{is}+q^{-is})\right)t} \tilde{u}(s, w, 0).
\]
Now we decompose,

\[
\tilde{u}(s, w, t) = \sum_{x \in T, h_w(x) > 0} u(x, t) q^{-h_w(x)/2} q^{-ish_w(x)} + \sum_{x \in T, h_w(x) \leq 0} u(x, t) q^{-h_w(x)/2} q^{-ish_w(x)}
\]

\[
= \sum_{k=0}^{+\infty} \frac{1}{q^{k/2}} \left( \sum_{x \in H^w_k} u(x, t) \right) \xi^k + \sum_{k=1}^{+\infty} \frac{1}{q^{k/2}} \left( \sum_{x \in H^{-w}_k} u(x, t) \right) \left( \frac{1}{\xi} \right)^k
\]

where \( \xi = q^{-is} \).

Now write \( b_0 = 1 \) and, for \( \ell \geq 1 \), \( b_\ell = \frac{1}{\sqrt{\ell}} \left( \frac{e}{2(q+1)\ell} \right)^\ell \) so that if \( t_j \in \{0, 1\} \),

\[
\sum_{x \in H^w_k} u(x, t_j) = \sum_{\ell=0}^{\infty} \sum_{x \in H^w_k \cap S_\ell} u(x, t_j) \leq \kappa \sum_{\ell=0}^{\infty} \psi_{\ell,k} b_\ell
\]

\[
\leq \begin{cases} 
\kappa q^k \left( b_k + (q-1) \sum_{p=1}^{\infty} q^{p-1} b_{k+2p} \right) & \text{for } k \geq 0 \\
\kappa \left( b_{-k} + (q-1) \sum_{p=1}^{\infty} q^{p-1} b_{-k-2p} \right) & \text{for } k \leq -1 
\end{cases}
\]

Using that \((k + 2p)^{k+2p+1/2} \geq k^{k+1/2}\) when \( k, p \geq 1 \), and that \((2p)^{2p+1/2} \geq 4\) we get that, for \( k \geq 1 \),

\[
\sum_{p=1}^{\infty} q^{p-1} b_{k+2p} = \left( \frac{e}{2(q+1)} \right)^k \frac{1}{q} \sum_{p=1}^{\infty} \left( \frac{e\sqrt{q}}{2(q+1)} \right)^{2p} \frac{1}{(k+2p)^{k+2p+1/2}} \leq \frac{1}{\sqrt{k}} \left( \frac{e}{2(q+1)k} \right)^k \frac{e^2}{4(q+1)^2 \left( 1 - \frac{e^2q}{4(q+1)^2} \right)} \leq b_k
\]
and the same bound holds for \( k = 0 \), thus

\[
\begin{align*}
\left| \sum_{x \in \mathcal{H}_k^w} u(x, t_j) \right| & \leq \begin{cases} 
\kappa q & \text{for } k = 0 \\
\kappa q^{k+1} b_k = \kappa q \frac{1}{\sqrt{k}} \left( \frac{eq}{2(q+1)k} \right)^k & \text{when } k \geq 1 \\
\kappa q b_{|k|} = \kappa q \frac{1}{\sqrt{|k|}} \left( \frac{e}{2(q+1)|k|} \right)^{|k|} & \text{when } k \leq -1
\end{cases}
\end{align*}
\]

It follows that

\[
\phi_j^+(\xi, w) := \sum_{k=0}^{+\infty} q^{-k/2} \left( \sum_{x \in \mathcal{H}_k^w} u(x, t_j) \right) \xi^k
\]

extends into an entire function in \( \xi \) of exponential type \( \sigma \). Its indicator diagram \( I_j^+ \) is therefore included in the closed disc \( \bar{D}(0, \sigma) \). On the other hand

\[
\phi_j^-(\zeta, w) := \sum_{k=1}^{+\infty} q^{k/2} \left( \sum_{x \in \mathcal{H}_k^w} u(x, t_j) \right) \zeta^k
\]

extends into an entire function in \( \zeta \) of exponential type \( \sigma \) as well and its indicator diagram \( I_j^- \) is therefore also included in the disc \( \bar{D}(0, \sigma) \).

Actually, a little more is shown, namely that

\[
|\phi_j^\pm(\xi, w)| \leq C_q^* \kappa e^{\sigma |\xi|},
\]

since we bound the corresponding coefficient of each sum by the \( k \)-th coefficient of the Taylor series of \( e^{\sigma |\xi|} \). This is the fact that motivates the use of the hypothesis (3.13) in this specific form.

Let us now turn back to (3.14) which we write as

\[
\tilde{u}(s, w, t) = e^{-i(1-2\sigma(\xi+\xi^{-1}))t} \left( \phi_0^- (\xi^{-1}, w) + \phi_0^+(\xi, w) \right).
\]

This holds a priori for \( \xi = q^{-is} \) and thus extends to \( \xi \in \mathbb{C} \setminus \{0\} \) and every \( t \). We write \( \tilde{u}(\xi, w, t) \) for the corresponding extension.

For \( t = 1 \) we obtain

\[
\phi_1^+(\xi, w) = -\phi_1^- (\xi^{-1}, w) 
+ e^{-i} \exp(2i\sigma(\xi + \xi^{-1})) \left( \phi_0^+ (\xi, w) + \phi_0^- (\xi^{-1}, w) \right).
\]

It follows that \( I_1^+ \subset I_0^+ + 2i\sigma \). As \( I_0^+, I_1^+ \subset \bar{D}(0, \sigma) \), this in turn implies that \( I_k^+ \) is reduced to \( i\sigma \) and \( I_{-k}^+ \) is reduced to \( -i\sigma \).

Let us now take \( t = 1/2 \). Then

\[
\tilde{u}(\xi, w, 1/2) = e^{-i/2} e^{i\sigma(\xi+\xi^{-1})} \left( \phi_0^- (\xi^{-1}, w) + \phi_0^+(\xi, w) \right).
\]
Write \( \tilde{u}(\xi, w, 1/2) = u_+ (\xi) + u_- (\xi^{-1}) \) where \( u_+ \) (resp. \( u_- \)) contains all terms of positive (resp. negative) exponent in the Laurent series of \( \tilde{u} \).

The indicator diagram of those functions coincide with \( \{0\} \) thus \( u_\pm \) are entire functions of 0 exponential type. On the other hand, (3.16) shows that \( u_\pm \) are bounded on \( i\mathbb{R} \).

Indeed, when \( \xi \to +\infty \),

\[
|u_+(i\xi)| \sim |	ilde{u}(i\xi, w, 1/2)| = |e^{-\sigma(\xi + \xi^{-1})}||\phi_0^- (i\xi^{-1}, w) + \phi_0^+(i\xi, w)| \\
\sim e^{-\sigma\xi}||\phi_0^+(i\xi, w)| \leq C_q \kappa.
\]

To see that \( u_+(i\xi) \) is also bounded when \( \xi \to -\infty \), let us write

\[
\tilde{u}(\xi, w, 1/2) = e^{-i/2}e^{-i\sigma(\xi + \xi^{-1})}(\phi_1^- (\xi^{-1}, w) + \phi_1^+(\xi, w)).
\]

On the other hand,

\[
|u_+(i\xi)| \sim |	ilde{u}(i\xi, w, 1/2)| = |e^{\sigma(\xi + \xi^{-1})}||\phi_1^- (i\xi^{-1}, w) + \phi_1^+(i\xi, w)| \\
\sim e^{\sigma\xi}||\phi_1^+(i\xi, w)| \leq C_q \kappa.
\]

The proof for \( |u_-(i\xi)| \) is similar but this time \( \xi \to 0^\pm \).

Now, according to the Phragmen-Lindelöf principle (see e.g. [Le, Lecture 6]) \( u_+ \) and \( u_- \) are constant and thus \( u \) is a constant as well.

It follows that

\[
\tilde{u}(s, w, 0) = C_w \exp(i(1 - \sigma(q^{is} + q^{-is}))
\]

for some constant \( C_w \) that depends on the ray \( w \). But, by definition, for \( \xi = q^{-is} \)

\[
\tilde{u}(\xi, w, 0) = \sum_{x \in T} u(x, 0) \left( \frac{\xi}{\sqrt{q}} \right)^{h_w(x)}
\]

and this extends to all \( \xi \in \mathbb{C} \setminus \{0\} \), in particular to \( \xi = \sqrt{q} \). This shows that

\[
C_w = \exp(-i(1 - \sigma(q^{1/2} + q^{-1/2}))) \sum_{x \in T} u(x, 0)
\]

does not depend on \( w \). We thus write \( C_w = C \).

The integral formula for \( u(|x|, 0) \) then comes from the inversion formula (2.11) and (see [CS])

\[
\int_{\partial T} q^{-(1/2-is)h_w(x)} d\nu(w) = c(-s)q^{(-(is-1/2)|x|} + c(-s)q^{(is-1/2)|x|},
\]

where \( c(s) = \frac{q^{1/2}q^{1/2+is} - q^{-1/2-is}}{q^{is} - q^{-is}} \).

As an immediate corollary, we have the following uniqueness property for strong solutions of (3.12):
Corollary 3.3. Assume that $u$ is a strong solution of the equation (3.12). Assume that there exists $\epsilon > 0$ and $\kappa$ such that, for $x \neq 0$

$$|u(x,t_i)| \leq \frac{\kappa}{\sqrt{|x|}} \left( \frac{e}{(2+\epsilon)(q+1)|x|} \right)^{|x|}, \ t_0 = 0, \ t_1 = 1.$$ 

Then $u \equiv 0$.

Remark 3.4. We leave as an exercise to the reader to check that, if $u$ is a strong solution of the equation $i\partial_t u(x,t) = \lambda \mathcal{L} u(x,t)$, with $u(x,0) = u_0(x)$, $\lambda > 0$ and if

$$|u(x,t_i)| \leq \frac{\kappa}{\sqrt{|x|}} \left( \frac{e\lambda}{2(q+1)|x|} \right)^{|x|}$$

then

$$u_0(x) = \frac{C}{q^{-|x|/2}} \int_0^\pi \exp \left( -i \frac{q^{1/2}\lambda}{q+1} \cos(z) \right) \varphi_{|x|}(x) \sin(z) \, dz$$

for some $C > 0$.

Note that when $\lambda = q + 1$, the condition (3.17) is the same for the tree $T_q$ and for $\mathbb{Z}$ so that the dependence on the tree is hidden.

4. Uniqueness for perturbed problems: the compact support case

In this section we want to apply similar techniques to solutions of equations of the form

$$i\partial_t u(x,t) = \mathcal{L} u(x,t) + \mathcal{V} u(x,t), \ x \in T,$$

where $\mathcal{V} u(x,t) = \sum_{y \in T} V(x,y) u(y,t)$ and $V$ is a compactly supported hermitian potential, $V(y,x) = \overline{V(x,y)}$. We denote by $\mathcal{K}$ for the smallest set such that the support of $\mathcal{V}$ is included in the set $\mathcal{K} \times \mathcal{K}$. Also $\mathcal{K}$ is included in $B_R = \{ x \in T, |x| \leq R \}$ for some $R$. In [CdVT] there is an extension of the Helgason-Fourier transformation in this context, and, for the sake of completeness, we recall here the main features.

We define the operator

$$A f(x) = \sum_{y \sim x} f(x) + \mathcal{W} f(x) = A_0 f(x) + \mathcal{W} f(x),$$

where, $\mathcal{W} = -(q+1)\mathcal{V}$, and we recall the Green’s functions of the operator $A_0$. For $s \in T \times i\mathbb{R}^+$,

$$G_0(s) f(x) = \sum_{y \in T} G_0(s,x,y) f(y), \ G_0(s,x,y) = \frac{q^{(-1/2+is)d(x,y)}}{q^{1/2-is} - q^{-1/2+is}}.$$
We define, for $s \in T$ and $w \in \partial T$ the functions $a(s, w, x)$ and $e(s, w, x)$ as the solutions of the following problems

$$
\begin{align*}
\left\{ 
\begin{array}{l}
a(s, w, x) = \chi_K e_0(s, w, x) + \chi_K G_0(s) [Wa(s, w)](x), \\
e(s, w, x) = e_0(s, w, x) + G_0(s) [Wa(s, w)](x),
\end{array}
\right.
\end{align*}
$$

where $e_0(s, w, x) = q^{-1/2 - is}h_w(x)$ and $\chi_K$ is the characteristic function of $K$. Those functions $e(s, w, x)$, known as generalized eigenfunctions related to the eigenvalue $\lambda_s = q^{1/2} + q^1s + q^{3/2 - is}$, will play the role of the eigenfunctions of $A$ and replace the function $e_0$ in the definition of the Fourier-Helgason transformation. This leads to the introduction of the deformed Fourier-Helgason transformation as

$$
\tilde{F}_T[f](s, w) = \sum_{x \in T} f(x)e(s, w, x).
$$

In [CdVT] it is shown that this formula is well defined for $\ell^2(T)$ functions and that it can be holomorphically extended to $s \in S^+ = T \times i\mathbb{R}^+$. Here again, $T = \mathbb{R}/\tau \mathbb{Z}$, identified with the interval $[-\tau/2, \tau/2]$, and $\tau = 2\pi/\log q$.

Further, there is a decomposition of $\ell^2(T) = H_{ac} \oplus H_{pp}$ where

— the space $H_{pp}$ is finite dimensional, admits an orthonormal basis of $\ell^2(T)$ eigenfunctions associated to a finite set of eigenvalues.

— $\tilde{F}_T[f] = 0$ if and only if $f \in H_{pp}$.

The actual statement [CdVT, Theorem 4.3] is stronger, but this is enough for our needs.

Thanks to the deformed Fourier-Helgason transformation, we are able to prove the main result of this section.

**Theorem 4.1.**

Let $V$ be a bounded and compactly supported hermitian potential and $V$ be defined by $V u(x) = \sum_{y \in T} V(x, y) u(y)$.

Let $u_0 \in H_{ac}$ and let $u \in C^1([0, 1], \ell^2(T))$ be a solution of

$$
i\partial_t u(x, t) = Lu(x, t) + Vu(x, t), \quad x \in T, \quad t \in [0, 1]
$$

with initial condition $u(\cdot, 0) = u_0$. Assume that, for some $\epsilon > 0$, at times $t_0 = 0$ and $t_1 = 1$ the solution satisfies the bound

$$
|u(x, t_j)| \leq C \frac{e}{\sqrt{|x|} \left( \frac{1}{(2 + \epsilon)(q + 1)|x|} \right)^{|x|}}, \quad j = 0, 1.
$$

Then $u \equiv 0$.

**Remark 4.2.** Alternatively, we may impose the bounds (4.20) on $\pi_{ac} u$, the projection of $u$ on $H_{ac}$ and conclude that $\pi_{ac} u = 0$. 

On the other hand, if \( u_0 \in \mathcal{H}_{pp} \), \( \mathcal{L}u + \mathcal{V}u = \lambda u \), then \( u(x,t) = e^{-i\lambda t}u_0(x) \). Such a solution has therefore the same decrease rate at any time. As shown in [CdVT], for certain \( \mathcal{V} \)'s, \( \mathcal{H}_{pp} \) may contain finitely supported functions on \( \mathbb{T} \) so that our theorem cannot hold without the restriction \( u_0 \in \mathcal{H}_{ac} \). However, in the case where every element of \( \mathcal{H}_{pp} \) is finitely supported, then if \( u \) satisfies (4.20) so does \( \pi_{ac}u \). As a consequence, the theorem remains valid provided we replace the conclusion \( u \equiv 0 \) by \( u_0 \in \mathcal{H}_{pp} \). Recall that this space is finite dimensional.

Note also that when \( \mathcal{V} \) is diagonal, i.e. \( \mathcal{V}u(x) = V(x)u(x) \) then there are no compactly supported eigenfunctions.

**Remark 4.3.** Before proving the theorem, let us compare this theorem with other results. As for Theorem A in the introduction, there is an extra-term given by \( \mathcal{V} \) but the conclusion is not as strong. The main difference with Theorem C is that the operator is not assumed to be diagonal here so that Theorem 4.1 has a slightly larger setting, though it has to be time-independent. This is done at the expense of assuming that \( \mathcal{V} \) is compactly supported. In summary, here \( \mathcal{V} \) is *not* diagonal but compactly supported, in Theorem C, \( \mathcal{V} \) is diagonal but *not* compactly supported (only bounded).

Theorem 4.1 can be seen as a tree analogue of the main result of [LyMa]. The first analogue of this result on \( \mathbb{Z} \) is [JLMP, Theorem 2.3], which is now a particular case of the main result of [FBV].

**Proof.** First note that if \( u_0 \in \mathcal{H}_{ac} \) then \( u(\cdot,t) \in \mathcal{H}_{ac} \) for all \( t \).

As we did in the free case, for a fixed \( w \in \partial \mathbb{T} \) we consider \( \tilde{u}_{sc} \) as the deformed Fourier-Helgason transform

\[
\tilde{u}_{sc}(s, w, t) = \sum_{x \in \mathbb{T}} u(x,t) \overline{e(s, w, x)}.
\]

As \( u \) takes values in \( \mathcal{H}_{ac} \), it is enough to show that \( \tilde{u}_{sc} = 0 \).

From [CdVT], we have again that

\[
\tilde{u}_{sc}(s, w, t) = e^{-i[1-2\sigma(qs+q^{-s})]t} \tilde{u}_{ac}^{sc}(s, w, 0).
\]
According to (4.19) we have

\[
\tilde{u}_{sc}(s, w, t) = \sum_{x \in T} u(x, t)q^{-h_{wu}(x)/2}q^{-ish_{wu}(x)}
\]

\[
+ \sum_{x \in T} u(x, t) \sum_{y \in K} \frac{q^{-(1/2+is)d(x,y)}}{q^{1/2+is} - q^{-1/2-is}} [Wa(s, w)](y)
\]

\[
= \sum_{x \in T} u(x, t)q^{-h_{wu}(x)/2}q^{ish_{wu}(x)}
\]

\[
+ \sum_{x \in T} u(x, t) \sum_{y \in K} \frac{q^{-d(x,y)/2}d(x,y)}{q^{1/2\xi} - q^{-1/2\xi}} [Wa(\xi, w)](y)
\]

\[
= \sum_{x \in T} u(x, t)q^{-h_{wu}(x)/2}
\]

\[
+ \sum_{x \in B_R} u(x, t) \sum_{y \in K} \frac{q^{-d(x,y)/2}d(x,y)}{q^{1/2\xi} - q^{-1/2\xi}} [Wa(\xi, w)](y)
\]

\[
+ \sum_{x \notin B_R} u(x, t) \sum_{y \in K} \frac{q^{-d(x,y)/2}d(x,y)}{q^{1/2\xi} - q^{-1/2\xi}} [Wa(\xi, w)](y)
\]

\[
= \Phi_1(\xi, w, t) + \Phi_2(\xi, w, t) + \Phi_3(\xi, w, t),
\]

with \(\xi = q^{-is}\). For the third sum, notice that, if we denote by \(x_K\) the closest point in \(K\) to \(x\), then for \(y \in K\), \(d(x, y) = d(x, x_K) + d(x_K, y)\). Hence, if \(x \notin B_R\), by (4.19),

\[
\sum_{y \in K} \frac{(q^{-1/2\xi})^{d(x,y)}}{(q^{-1/2\xi})^{1/2} - q^{-1/2\xi}} [Wa(\xi, w)](y)
\]

\[
= (q^{-1/2\xi})^{d(x,x_K)} \left( a(\xi, w, x_K) - (q^{-1/2\xi})^{-h_{wu}(x_K)} \right).
\]

Notice that, from (4.19), it is easy to check that \(a(\xi, w, x)\) is a rational polynomial in the variable \(\xi\), so, since \(x_K \in K\), there exists \(M = M(R)\) such that, for \(|\xi|\) large enough, to avoid the (finite number of) poles of \(a(\xi, w, x_K) - (q^{-1/2\xi})^{-h_{wu}(x_K)}\), we have

\[
|a(\xi, w, x_K) - (q^{-1/2\xi})^{-h_{wu}(x_K)}| \leq C|\xi|^M.
\]

Moreover, thanks to the decay hypothesis, at \(t = 0\) and \(t = 1\) the three different sums are holomorphic in the region \(\{|\xi| > 1\}\) except perhaps at a finite number of poles. Let us study separately each sum
in that region. First,

\[ |\Phi_1(\xi, w, t)| = \left| \sum_{x \in \mathcal{T}} u(x, t)(q^{-1/2}\xi)^{-h_w(x)} \right| \leq C + \sum_{x \in \mathcal{T}, h_w(x) < 0} |u(x, t)||q^{-1/2}\xi|^{-h_w(x)}. \]

This sum corresponds to the free evolution, so we can repeat exactly the same argument we use to get (3.16) to get

\[ |\Phi_1(\xi, w, t)| \leq e^{\sqrt{q}(2+\epsilon)(q+1)|\xi|}, \]

and this sum extends to an exponential function of type \( \sqrt{q}(2+\epsilon)(q+1) \).

Hence, at \( t = 0 \) and \( t = 1 \), for any \( \alpha \),

\[ \limsup_{r \to \infty} \frac{\log |\Phi_1(re^{i\alpha}, w, t)|}{r} \leq \frac{\sqrt{q}}{(2+\epsilon)(q+1)}. \]

Now, since for \( x \in B_R, y \in K \) we have \( |d(x, y)| \leq 2R \), there exists \( M = M(R) \) such that

\[ |\Phi_2(\xi, \omega, t)| = \left| \sum_{x \in B_R} u(x, t) \sum_{y \in K} (q^{-1/2}\xi)^{d(x, y)} (q^{-1/2}\xi)^{-1} - q^{-1/2}\xi \right| \]

\[ \leq C\|\Psi\|_\infty|\xi|^M \sum_{x \in B_R} |u(x, t)|. \]

Thus, since \( u \in \ell^2(\mathcal{T}) \), at \( t = 0 \) and \( t = 1 \), for any \( \alpha \),

\[ \limsup_{r \to \infty} \frac{\log |\Phi_2(re^{i\alpha}, w, t)|}{r} = 0. \]

Finally, we have to study \( |\Phi_3(\xi, w, t)| \):

\[ \left| \sum_{x \notin B_R} u(x, t)(q^{-1/2}\xi)^{d(x, x_K)} \left( \frac{d(x, x_K)}{d(\xi, w, x_K)} - (q^{-1/2}\xi)^{-h_w(x_K)} \right) \right| \leq |\xi|^M \sum_{x \notin B_R} |u(x, t)||q^{-1/2}\xi|^{d(x, x_K)}. \]

Let us consider, for \( j \geq 1 \), the points \( x \in \mathcal{T} \) such that \( |x| = R + j \). Notice that there are \( q^{R+j-1}(q+1) \) such points and that, for each such
point, $d(x, x_K) \leq j + 2R$. Hence, setting $b_\ell = \frac{1}{\sqrt{\ell}} \left( \frac{e}{(2 + \epsilon)(q + 1)} \right)^{\ell}$, we have
\[
\sum_{x \not\in B_R} |u(x, t)||q^{-1/2}\xi|^{d(x, x_K)} \leq \sum_{j \geq 1} q^{R + j - 1}(q + 1)|b_{R+j}|q^{-1/2}\xi|^{j+2R} = \frac{q + 1}{q}|q^{-1/2}\xi|^R \sum_{j \geq 1} |b_{R+j}||q^{1/2}\xi|^{R+j}.
\]
Finally, the sum on the right-hand side is bounded by $e^{\frac{\sqrt{q}q}{(2+\epsilon)(q+1)}}$, so we get
\[
\limsup_{r \to \infty} \frac{\log |\Phi_3(re^{i\alpha}, w, t)|}{r} \leq \frac{\sqrt{q}}{(2 + \epsilon)(q + 1)}.
\]
Gathering the results for $\Phi_i$, $i = 1, 2, 3$ we conclude that, at $t = 0$ and $t = 1$, for any $\alpha$,
\[
\limsup_{r \to \infty} \frac{\log |\tilde{u}_{sc}(re^{i\alpha}, w, t)|}{r} \leq \frac{\sqrt{q}}{(2 + \epsilon)(q + 1)}.
\]
Using (2.9), if $\tilde{u}_{sc} \not\equiv 0$, we get that, at $t = 0$ and $t = 1$, for any $\alpha$,
\[
\limsup_{r \to \infty} \frac{\log |\tilde{u}_{sc}(re^{i\alpha}, w, t)|}{r} \geq \frac{-\sqrt{q}}{(2 + \epsilon)(q + 1)}.
\]
Now, let us recall that, from (4.21), if $g(\xi) = \exp\{-i(1-2\sigma(\xi + \xi^{-1})\}$
\[
\tilde{u}_{sc}(\xi, w, 1) = g(\xi)\tilde{u}_{sc}(\xi, w, 0)
\]
and, furthermore,
\[
\limsup_{y \to +\infty} \frac{\log |g(-iy)|}{y} = 2\sigma = \frac{\sqrt{q}}{(q + 1)}.
\]
We then have
\[
\limsup_{y \to +\infty} \frac{\log |\tilde{u}_{sc}(-iy, w, 1)|}{y} = \frac{\sqrt{q}}{(q + 1)} + \limsup_{y \to +\infty} \frac{\log |\tilde{u}_{sc}(-iy, w, 0)|}{y} \geq \frac{\sqrt{q}}{(q + 1)} - \frac{\sqrt{q}}{(2 + \epsilon)(q + 1)} > \frac{\sqrt{q}}{(2 + \epsilon)(q + 1)},
\]
which contradicts (4.22). Thus $\tilde{u}_{sc} \equiv 0$ thus $u \equiv 0$. \qed
5. Uniqueness for perturbed problems using Carleman estimates

In this section we consider the simplified problem

\begin{equation}
\partial_t u = i(\mathcal{L}u + Vu)
\end{equation}

where now \( V = V(x,t) \) is a bounded potential. In other words, compared to the previous section, the potential is now time-dependent and diagonal, but no longer of compact support, just bounded.

We are going to begin this section by pointing out that a fast decaying solution at times \( t = 0 \) and \( t = 1 \) extends the fast decay to the whole interval \([0,1]\). This is given by an immediate extension of part of the results in [JLMP]. For convenience, the equation is written in a different way. In any case, by doing a suitable change of variables one can see that the results described in this section can be rewritten in terms of a solution of \( i\partial_t u = \mathcal{L}u + Vu \). We first need an auxiliary lemma:

**Lemma 5.1.**

Let \( u \in C^1([0,T], \mathbb{T}) \) satisfy (5.23) where \( V \) is a complex valued functions in \( T \times [0,T] \) and bounded. Let

\[ \psi_\alpha(x, t) = (1 + |x|)^{\alpha|x|/(1+t)}, \quad \alpha \in (0, 1]. \]

Then, for \( T > 0 \),

\[ \|\psi_\alpha(T)u(T)\|_2^2 \leq e^{CT}\|\psi_\alpha(0)u(0)\|_2^2, \]

provided the right-hand side is finite.

**Remark 5.2.** This is a tree analogue of [JLMP, Proposition 3.1]. We may as well consider the more general equation

\[ \partial_t u(x,t) = i(\mathcal{L}u(x,t) + V(x,t)u + F(x,t)), \]

where \( V \) and \( F \) are complex valued functions in \( T \times [0,T] \) and bounded. In this case, a simple adaptation of the proof below shows that

\[ \|\psi_\alpha(T)u(T)\|_2^2 \leq e^{CT}\left(\|\psi_\alpha(0)u(0)\|_2^2 + \int_0^T \|\psi_\alpha(s)F(s)\|_2^2 \, ds\right), \]

provided the right-hand side is finite.

**Proof.** Define \( f(x, t) = \psi_\alpha(x,t)u(x,t) \) and \( H(t) = \|f(t)\|_2^2 \) for a fixed \( \alpha \). We will just write \( \psi = \psi_\alpha \). Notice that \( \psi \) only depends on \(|x|\), so for \(|x| = n \) we write \( \psi(x) = \psi(n) \).

Formally,

\[ \partial_t f = i\psi \mathcal{L}(\psi^{-1} f) + \phi_t f + iVF = \mathcal{S}f + Af + iVf, \]
where $\phi = \log \psi$ and

$$Sf = \phi_t f + \frac{i}{q + 1} \sum_{y \sim x} \sinh(\phi(x, t) - \phi(y, t)) f(y)$$

$$Af = \frac{i}{q + 1} \sum_{y \sim x} \cosh(\phi(x, t) - \phi(y, t)) f(y) - if(x).$$

are symmetric and skew-symmetric operators respectively. Since

$$\partial_t H(t) = 2\Re\langle \partial_t f, f \rangle,$$

it is easy to check that $\partial_t H(t)$ is bounded by

$$\leq \|V\|_\infty \|f\|_2$$

$$+ \left( 2\phi_t(0) + \frac{2}{\sqrt{q}} |\sinh(\phi(1) - \phi(0))| \right) |f(o)|^2$$

$$+ \sum_{n \geq 1, |x| = n} \left( 2\phi_t(n) + \frac{2\sqrt{q}}{q + 1} |\sinh(\phi(n) - \phi(n - 1))| \right) |f(x)|^2$$

$$+ \frac{2\sqrt{q}}{q + 1} \sum_{n \geq 1, |x| = n} |\sinh(\phi(n + 1) - \phi(n))||f(x)|^2.$$

The result follows after proving that the last three terms are bounded by $C\|f\|_2$, in the same spirit as in [JLMP]. To justify this formal argument, we can prove again the same result (now rigorously) for a truncated weight $\psi_N$ and then let $N \to \infty$ (See [JLMP] for this argument in the line $Z$).

This result shows that if we have a solution of (5.23) with fast decay at time $t = 0$, the solution has fast decay at any future time, although the decay gets worse with time. Our aim now is to use also the fast decay at time $t = 1$ to improve the decay at future times.

**Proposition 5.3.**

Let $\gamma > 0$ and $V$ a bounded potential. Let $u$ be a strong solution of (5.23) and assume that at times $t = 0$ and $t = 1$,

$$\|(1 + |x|)^{\gamma(1+|x|)}u(x, t)\|_2 < +\infty, \quad t \in \{0, 1\}.$$

Then, for all $t \in [0, 1]$, $\|(1 + |x|)^{\gamma(1+|x|)}u(t)\|_2 < +\infty$.

**Remark 5.4.** This is the tree analogue of [JLMP, Proposition 4.1] on $Z$. Some basic calculus facts will be taken from the proof of this proposition will also be used here.
\textbf{Proof.} For $1/2 < b < 1$, let $\phi_n(n) = \gamma(1+n) \log^b(1+n)$, $n \in \mathbb{N} \cup \{0\}$. Set $f = e^{\phi_b(|x|)}u$ and, as before $H(t) = \|f(t)\|^2_2$. The previous lemma shows that $H(t)$ is finite for all $t$, so the subsequent formal computations are justified. We will show that, for some $C > 0$,

\[ H_b(t) \leq e^{C t(1-t)} H_b(0)^{1-t} H_b(1)^t \]

\[ \leq e^{C t(1-t)} \|(1 + |x|)^{\gamma(1+|x|)} u(0)\|_2^{2(1-t)} \|(1 + |x|)^{\gamma(1+|x|)} u(1)\|_2^{2t}. \]

The result will follow by letting $b \to 1$ and applying the monotone convergence theorem.

In order to prove our claim, we write again $\partial_t f = \mathcal{S}f + \mathcal{A}f + iVf$ and, as shown in [JLMP], the claim follows from a lower bound

\begin{equation}
\langle [\mathcal{S}, \mathcal{A}]f, f \rangle \geq -C\|f\|^2,
\end{equation}

with $\mathcal{S}, \mathcal{A}$ the operators defined in the previous lemma, in this case for the weight $e^{\phi_b}$. Since $\phi_b$ does not depend on $t$, it is easy to check that $(q + 1)^2 \langle [\mathcal{S}, \mathcal{A}]f, f \rangle$ is

\[ = \sum_{x \in \mathcal{T}} \sum_{y \sim x} \sum_{z \sim y} \sinh (2\phi_b(|y|) - \phi_b(|x|) - \phi_b(|z|)) f(z) \overline{f(x)} \]

\[ = \sinh (2\phi_b(1) - 2\phi_b(0)) |f(o)|^2 \]

\[ + 2 \sinh (2\phi_b(1) - \phi_b(0) - \phi_b(2)) \Re \sum_{z \in o_{ff}} f(z) \overline{f(o)} \]

\[ + \sum_{x \in \mathcal{T} \setminus \{o\}} \sinh (2\phi_b(|x| - 1) - 2\phi_b(|x|)) \sum_{z \in x_{pf}} f(z) \overline{f(x)} \]

\[ + \sum_{x \in \mathcal{T} \setminus \{o\}} \sinh (2\phi_b(|x| - 1) - 2\phi_b(|x|)) |f(x)|^2 \]

\[ + 2 \Re \sum_{x \in \mathcal{T} \setminus \{o\}} \sinh (2\phi_b(|x| + 1) - \phi_b(|x|) - \phi_b(|x| + 2)) \sum_{z \in x_{ff}} f(z) \overline{f(x)} \]

\[ + \sum_{x \in \mathcal{T} \setminus \{o\}} \sinh (2\phi_b(|x| + 1) - 2\phi_b(|x|)) |f(x)|^2 \]

\[ = S_1 + \ldots + S_6. \]

As for each $n$, there exists $\gamma_n$ such that, for every $1/2 < b < 1$, $|\Phi_b(n)| \leq \gamma_n$, there exists a constant $C$ such that $S_1, S_2 \geq -C\|f\|^2$.

As in [JLMP], there exists a constant $\kappa$ such that, for every $n$, $|\sinh (2\phi_b(n + 1) - \phi_b(n) - \phi_b(n + 2))| \leq \kappa$. Further, $|x_{ff}| = q^2$ so that Cauchy-Schwarz shows that there is a constant $C$ such that $S_5 \geq -C\|f\|^2$. 

Next, if $|x| \geq 2$, 

$$\left| \sum_{z \in x_{pf}} f(z) \overline{f(x)} \right| \leq \frac{1}{2} \sum_{z \in x_{pf}} (|f(z)|^2 + |f(x)|^2)$$

$$= \frac{q-1}{2} |f(x)|^2 + \frac{1}{2} \sum_{z \in x_{pf}} |f(z)|^2,$$

while if $|x| = 1$, 

$$\left| \sum_{z \in x_{pf}} f(z) \overline{f(x)} \right| \leq \frac{q}{2} |f(x)|^2 + \frac{1}{2} \sum_{z \in x_{pf}} |f(z)|^2,$$

But then

$$S_3 \geq \frac{1}{2} \sum_{x \in T \setminus \{o\}} \sinh (2\phi_b(|x|) - 2\phi_b(|x| - 1)) \sum_{z \in x_{pf}} |f(z)|^2$$

$$- \frac{q-1}{2} \sum_{|x| \geq 2} \sinh (2\phi_b(|x|) - 2\phi_b(|x| - 1)) |f(x)|^2$$

$$- \frac{q}{2} \sum_{|x| = 1} \sinh (2\phi_b(1) - 2\phi_b(0)) |f(x)|^2$$

$$= -(q-1) \sum_{x \in T \setminus \{o\}} \sinh (2\phi_b(|x|) - 2\phi_b(|x| - 1)) |f(x)|^2$$

$$- \sum_{|x| = 1} \sinh (2\phi_b(1) - 2\phi_b(0)) |f(x)|^2$$

$$= S_3^a + S_3^b$$

since each $x \in T \setminus \{o\}$ appears $q - 1$ times (resp. $q$ times) in the first sum if $|x| \geq 2$ (resp. $|x| = 1$). It follows that $S_3^b \geq -C\|f\|^2$ and

$$S_3^a + S_4 + S_6 \geq q \sum_{x \in T \setminus \{o\}} \psi_b(|x|) |f(x)|^2 \geq 0$$

where

$$\psi_b(n) = \sinh (2\phi_b(n + 1) - 2\phi_b(n)) - \sinh (2\phi_b(n) - 2\phi_b(n - 1)) \geq 0$$

due to the properties of the function $(1 + x) \log^b (1 + x)$ for $x > 0$ and $1/2 < b < 1$, see [JLMP].

As it happens in the continuous case, or in $\mathbb{Z}^d$, uniqueness holds from an argument related to Carleman inequalities. Here we prove the following Carleman inequality:
Lemma 5.5 (Carleman inequality on the tree).
Let \( \varphi : [0, 1] \to \mathbb{R} \) be a smooth function, \( \beta > 0 \) and \( \gamma > \frac{1}{2\beta} \). There exists \( R_0 = R_0(\|\varphi\|_{\infty} + \|\varphi'\|_{\infty} + \|\varphi''\|_{\infty}, \beta, \gamma) \) such that, if \( R > R_0 \), \( \alpha \geq \gamma R \log R \) and if \( g \) is a function on \( T \times [0, 1] \), \( g \in C_0^1([0, 1], \ell^2(T)) \) has its support contained in the set
\[
\{(x, t) : |x|/R + \varphi(t) \geq \beta\},
\]
then
\[
\sinh \frac{2\alpha}{R^2} \cosh \frac{4\alpha\beta}{R} \|e^{\alpha(|x|/R + \varphi)} g 1_{|x|\geq 1}\|_{L^2_{x,t}}^2 \\
\leq (q + 1)^2 \|e^{\alpha(|x|/R + \varphi)} (i\partial_t + \mathcal{L}) g\|_{L^2_{x,t}}^2 \\
+ \int_0^1 \sinh \frac{4\alpha}{R} \left( \frac{1}{2R} + \varphi \right) \sum_{|x|=1} \|e^{\alpha(|x|/R + \varphi)} g(x)\|^2 dt.
\]

Remark 5.6. In the case of \( Z \) or, in general, of \( Z^d \), where the combinatorics makes the study of the problem easier this corresponds to [FBV, Lemma 2.1]. Further, on the tree, the inequality contains an extra-term. Fortunately, this term will be harmless.

Proof. Let \( \phi \) be defined by \( \phi(n) = \alpha \left( \frac{n}{R} + \varphi(t) \right)^2 \). For \( f = e^\phi g \) we have,
\[
e^{\phi}(i\partial_t + \mathcal{L})g = Sf + Af,
\]
where
\[
Sf = i\partial_t f + \frac{1}{q + 1} \sum_{y \sim x} \cosh(\phi(x, t) - \phi(y, t)) f(y, t) - f,
\]
\[
Af = -i\phi_t f + \frac{1}{q + 1} \sum_{y \sim x} \sinh(\phi(x, t) - \phi(y, t)) f(y, t).
\]

We need to give a lower bound for the commutator, which immediately implies the result using the fact that
\[
\|e^{\alpha(|x|/R + \varphi(t))^2} (i\partial_t + \mathcal{L}) g\|_{L^2_{x,t}}^2 \geq \langle [S, A] f, f \rangle.
\]

To simplify notation, we will not explicitly write the dependence of \( f \) on the time variable \( t \) so that \( f(x) \) means \( f(x, t), x \in T, t \in [0, 1] \). A simple computation shows that
\[
\langle [S, A] f, f \rangle = \int_0^1 S(t) dt \tag{5.25}
\]
where

\[ S(t) := \sum_{x \in T} \phi_t(x)|f(x)|^2 \]

\[ + \frac{2}{q+1} \sum_{x \in T} \sum_{y \sim x} (\phi_t(x) - \phi_t(y)) \cosh(\phi(x) - \phi(y)) f(y) \overline{f(x)} \]

\[ + \frac{1}{(q+1)^2} \sum_{x \in T} \sum_{y \sim x} \sum_{z \sim y} \sinh(2\phi(y) - \phi(x) - \phi(z)) f(z) \overline{f(x)} \].

As in the previous proof, we split them into sums over mothers and daughters. Recall that the root has only daughters while the rest of the points in the tree have a single mother and \( q \) daughters. Further, the function \( \phi(x,t) \) only depends on \( |x| \), the distance of a point in the tree to the root \( o \). We therefore decompose the sums in (5.26) as follows:

\[ S(t) = S_1 + \cdots + S_7 \] where

- The first sum in (5.26) is \( S_1 = \sum_{|x| = n} \sum_{n \geq 0} \phi_t(n)|f(x)|^2 \).

- For the second sum in (5.26), each pair \( x \sim y \) appears twice, once \( |x| = |y| + 1 \), once with \( |x| = |y| - 1 \). Therefore, this sum can be rewritten as

\[ S_2 = \frac{4}{q+1} \Im \sum_{n \geq 1} \sum_{|x| = n} (\phi_t(n) - \phi_t(n-1)) \cosh(\phi(n) - \phi(n-1)) f(x) \overline{f(x)} \].

- For the last sum in (5.26), we need to distinguish more cases:
  a) \( x = o, \ y \) any daughter and \( z = o \). This happens \( q+1 \) times and leads to

\[ S_3 = \frac{1}{q+1} \sinh 2(\phi(1) - \phi(0)) |f(o)|^2 ; \]

  b) \( x \in T \setminus \{ o \}, \ i.e. \ n := |x| \geq 1 \ y \) is one of the \( q \) daughters of \( x \) and \( z = x \) which leads to

\[ S_4 = \frac{q}{(q+1)^2} \sum_{n \geq 1} \sum_{|x| = n} \sinh 2(\phi(n+1) - \phi(n)) |f(x)|^2 \]

while if \( y \) is the mother of \( x \) and \( z = x \), we get

\[ S_5 = \frac{1}{(q+1)^2} \sum_{n \geq 1} \sum_{|x| = n} \sinh 2(\phi(n-1) - \phi(n)) |f(x)|^2 ; \]

  c) \( x \in T \setminus \{ o \}, \ i.e. \ n := |x| \geq 1, \ y \) is the mother of \( x \) and \( z \) is any of the sisters of \( x \), we get

\[ S_6 = \frac{1}{(q+1)^2} \sum_{n \geq 1} \sum_{|x| = n} \sum_{z \in x_{pf}} \sinh 2(\phi(n-1) - \phi(n)) |f(z)| \overline{f(x)} ; \]
— Finally, for all other terms \(x\) is the grand-mother of \(z\) and each such couple \((x, z)\) appears twice. As \(|z| \geq 2\), this may be written as
\[
S_7 = \frac{2}{(q + 1)^2} \Re \sum_{n \geq 2} \sum_{|x|=n} \sinh(2\phi(n - 1) - \phi(n) - \phi(n - 2)) f(x) \overline{f(x_{pp})}.
\]

Before estimating those quantities, as \(\phi(n) = \alpha \left( \frac{n}{R} + \varphi(t) \right)^2\), we obtain
\[
\phi_t(n) = 2\alpha \left( \frac{n}{R} + \varphi \right) \varphi',
\]
\[
\phi_{tt}(n) = 2\alpha \left( \frac{n}{R} + \varphi \right) \varphi'' + (\varphi')^2.
\]
\[
\phi_t(n) - \phi_t(n - 1) = \frac{2\alpha}{R} \varphi',
\]
\[
\phi(n - 1) - \phi(n) = -\frac{2\alpha}{R} \left( \frac{n - 1/2}{R} + \varphi \right)
\]
\[
\phi(n) + \phi(n + 2) - 2\phi(n + 1) = \frac{2\alpha}{R^2}.
\]

Let us now estimate \(S_1\) to \(S_7\). We will treat them from the simplest to the most involved one rather than the order in which they appeared in the above decomposition. We start with \(S_1\), which can be bounded by
\[
S_1 \geq -2\|\varphi''\|_{\infty} \alpha \sum_{n \geq 0} \left| \frac{n}{R} + \varphi \right| \sum_{|x|=n} |f(x)|^2.
\]

To estimate \(S_7\), we write \(2\Re(f(x)f(x_{pp}) = -|f(x) - f(x_{pp})|^2 + |f(x)|^2 + |f(x_{pp})|^2\), then
\[
S_7 = \frac{\sinh \frac{2\alpha}{R^2}}{(q + 1)^2} \sum_{n \geq 2} \sum_{|x|=n} \left( |f(x) - f(x_{pp})|^2 - |f(x)|^2 - |f(x_{pp})|^2 \right)
\]
\[
\geq -\frac{\sinh \frac{2\alpha}{R^2}}{(q + 1)^2} \left( \sum_{n \geq 2} \sum_{|x|=n} |f(x)|^2 + \sum_{n \geq 2} \sum_{|x|=n} |f(x_{pp})|^2 \right)
\]
\[
\geq -\frac{\sinh \frac{2\alpha}{R^2}}{(q + 1)^2} \left( q(q + 1)|f(o)|^2 + q^2 \sum_{|x|=1} |f(x)|^2 \right)
\]
\[
(5.28) \quad + (q^2 + 1) \sum_{n \geq 2} \sum_{|x|=n} |f(x)|^2
\]
since $o$ has $q(q + 1)$ grand-daughters, it appears $q(q + 1)$ times as an $x_{zp}$, if $|x| \geq 1$, it has $q^2$ grand-daughters and thus will appear $q^2$ times in the second sum.

Next, for $S_6$, we use that $f(z)f(x) \geq -\frac{1}{2}(|f(x)|^2 + |f(z)|^2)$ to obtain

$$S_6 \geq -\frac{1}{2(q + 1)^2} \sum_{n \geq 1} |\sinh 2(\phi(n - 1) - \phi(n))| \times$$

$$\times \sum_{|x|=n} \sum_{z \in x_{zp}} (|f(x)|^2 + |f(z)|)$$

$$= -\frac{1}{(q + 1)^2} \left(q |\sinh 2(\phi(0) - \phi(1))| \sum_{|x|=1} |f(x)|^2ight.$$

$$+ (q - 1) \sum_{n \geq 1} |\sinh 2(\phi(n - 1) - \phi(n))| \sum_{|x|=n} |f(x)|^2 \right).$$

Here we use the fact that $x_{zp}$ has $q$ elements if $|x| = 1$ and $q - 1$ elements otherwise for $\sum_{|x|=n} \sum_{z \in x_{zp}} |f(x)|^2$ and we use (2.10) for the second sum. Finally, using the expression of $\phi$, we get

$$S_6 \geq -\frac{1}{(q + 1)^2} \left(q \sinh \frac{4\alpha}{R} \left(\frac{1}{2R} + \varphi\right) \sum_{|x|=1} |f(x)|^2ight.$$

$$+ (q - 1) \sum_{n \geq 2} \sinh \frac{4\alpha}{R} \left(\frac{n - 1/2}{R} + \varphi\right) \sum_{|x|=n} |f(x)|^2 \right).$$

(5.29) $S_6 \geq -\frac{1}{(q + 1)^2} \left(q \sinh \frac{4\alpha}{R} \left(\frac{1}{2R} + \varphi\right) \sum_{|x|=1} |f(x)|^2ight.$

$$+ (q - 1) \sum_{n \geq 2} \sinh \frac{4\alpha}{R} \left(\frac{n - 1/2}{R} + \varphi\right) \sum_{|x|=n} |f(x)|^2 \right).$$

Now, for $S_6$, let us first introduce

$$\Psi(n) = \cosh(\phi(n) - \phi(n - 1))$$

and

$$\Sigma_n = \sum_{|x|=n} (q^{1/2}|f(x)|^2 + q^{-1/2}|f(x_p)|^2).$$

We use the expression of $\phi_t$ and the fact that

$$2|f(x)f(x_p)| \leq q^{1/2}|f(x)|^2 + q^{-1/2}|f(x_p)|^2$$

to bound $S_6$ by

$$\geq -\frac{4\alpha|\varphi'|}{(q + 1)R} \sum_{n \geq 1} \Psi(n)\Sigma_n$$

$$= -\frac{4\alpha|\varphi'|}{q^{1/2}R} \Psi(1)|f(o)|^2 - \frac{4q^{1/2}\alpha|\varphi'|}{(q + 1)R} \sum_{n \geq 1} \sum_{|x|=n} [\Psi(n) + \Psi(n + 1)] |f(x)|^2$$
since \( o \) will appear \( q + 1 \) times as an \( x_p \) and each \( x \) with \( |x| \geq 1 \) will appear once as an \( x \) and \( q \) times as an \( x_p \). Using the expression of \( \phi \) we conclude that

\[
S_2 \geq -\frac{4\alpha \|\varphi''\|_{\infty}}{Rq^{1/2}} \cosh \frac{2\alpha}{R} \left( \frac{1}{2R} + \varphi \right) |f(o)|^2
- \frac{4q^{1/2} \alpha \|\varphi''\|_{\infty}}{(q + 1)R} \cosh \frac{\alpha}{R^2} \sum_{n \geq 1} \cosh \frac{2\alpha}{R} \left( \frac{n}{R} + \varphi \right) \sum_{|x| = n} |f(x)|^2.
\]

Next, write

\[
S_4 = \frac{q - 1}{(q + 1)^2} \sum_{n \geq 1} \sum_{|x| = n} \sinh 2(\phi(n + 1) - \phi(n)) |f(x)|^2
+ \frac{1}{(q + 1)^2} \sum_{n \geq 1} \sum_{|x| = n} \sinh 2(\phi(n + 1) - \phi(n)) |f(x)|^2
= S_4^a + S_4^b.
\]

We will group \( S_4^b \) and \( S_5 \) noticing that

\[
\sinh \frac{4\alpha}{R} \left( \frac{n + 1/2}{R} + \varphi \right) - \sinh \frac{4\alpha}{R} \left( \frac{n - 1/2}{R} + \varphi \right)
= 2 \cosh \frac{4\alpha}{R} \left( \frac{n}{R} + \varphi \right) \sinh \frac{2\alpha}{R^2}.
\]

This leads to

\[
S_4^b + S_5 \geq \frac{2}{(q + 1)^2} \sinh \frac{2\alpha}{R^2} \sum_{n \geq 1} \cosh \frac{4\alpha}{R} \left( \frac{n}{R} + \varphi \right) \sum_{|x| = n} |f(x)|^2.
\]

We are now in position to estimate \( S_1 + \cdots + S_7 \). Let us first isolate all terms containing \( |f(o)|^2 \). They appear in (5.27), \( S_3 \), (5.28) and (5.30).

The factor of \( |f(o)|^2 \) is

\[
A := -2\alpha \|\varphi\|_{\infty} \|\varphi''\|_{\infty} + \frac{1}{q + 1} \sinh \frac{4\alpha}{R} \left( \frac{1}{2R} + \varphi \right)
- \frac{q \sinh \frac{2\alpha}{R}}{q + 1} - \frac{4\alpha \|\varphi''\|_{\infty}}{Rq^{1/2}} \cosh \frac{2\alpha}{R} \left( \frac{1}{2R} + \varphi \right).
\]

Now, the hypothesis of the lemma show that, if \( f(o) \neq 0 \), then \( \varphi \geq \beta > 0 \). Further, as \( \alpha > \frac{1}{2\beta} R \log R \), it is easy to see that the dominating term in \( A \) is the second one and that the other three can be absorbed in it provided \( R \) is large enough. Thus \( A \geq 0 \) if \( R \) is large enough (depending on \( q \), \( \|\varphi\|_{\infty}, \|\varphi'\|_{\infty}, \|\varphi''\|_{\infty} \) and \( \beta \)).
Next, we compute the factor of \( \sum_{|x|=1} |f(x)|^2 \). The one stemming from \( S_4^a \) and the one appearing in (5.29) give

\[
\frac{q - 1}{(q + 1)^2} \sinh \frac{4\alpha}{R} \left( \frac{3}{2R} + \varphi \right) - \frac{q}{(q + 1)^2} \sinh \frac{4\alpha}{R} \left( \frac{1}{2R} + \varphi \right) \geq - \frac{1}{(q + 1)^2} \sinh \frac{4\alpha}{R} \left( \frac{1}{2R} + \varphi \right). 
\]

The remaining terms for \(|x|=1\) come from (5.31), (5.30), (5.28) and (5.27). The factor of \( \sum_{|x|=1} |f(x)|^2 \) stemming from those terms is

\[
\frac{2}{(q + 1)^2} \sinh \frac{2\alpha}{R^2} \cosh \frac{4\alpha}{R} \left( \frac{1}{R} + \varphi \right) - \frac{4q^{1/2} \|\varphi'\|_{\infty}}{(q + 1)R} \cosh \frac{\alpha}{R^2} \cosh \frac{2\alpha}{R} \left( \frac{1}{R} + \varphi \right) \geq - \frac{q^2 \sinh \frac{2\alpha}{R^2}}{(q + 1)^2} - 2\|\varphi''\|_{\infty, \alpha} \left| \frac{1}{R} + \varphi \right|. 
\]

The three last terms are again absorbed in the first one (see the proof of [FBV, Lemma 2.1] for details). We are thus left with

\[
\frac{1}{(q + 1)^2} \sinh \frac{2\alpha}{R^2} \cosh \frac{4\alpha}{R} \left( \frac{1}{R} + \varphi \right) \sum_{|x|=1} |f(x)|^2 \geq \frac{1}{(q + 1)^2} \sinh \frac{2\alpha}{R^2} \cosh \frac{4\alpha\beta}{R} \sum_{|x|=1} |f(x)|^2
\]

because of the support property of \( f \).

For \( n \geq 2 \) the factor of \( \sum_{|x|=n} |f(x)|^2 \) come from

— first those from \( S_4^a \) and from (5.29) which now are

\[
\frac{q - 1}{(q + 1)^2} \sinh \frac{4\alpha}{R} \left( \frac{n + 1/2}{R} + \varphi \right) - \frac{q - 1}{(q + 1)^2} \sinh \frac{4\alpha}{R} \left( \frac{n - 1/2}{R} + \varphi \right) \geq 0, 
\]
— the remaining ones coming from (5.27), (5.28), (5.30) and (5.31)

\[ -2\|\varphi''\|_\infty \alpha \frac{n}{R} + \varphi - \frac{q^2 + 1}{(q + 1)^2} \sinh \frac{2\alpha}{R^2} \]

\[ - \frac{4q^{1/2}\|\varphi'\|_\infty}{(q + 1)R} \cosh \frac{\alpha}{R^2} \cosh \frac{2\alpha}{R} \left( \frac{n}{R} + \varphi \right) \]

\[ + \frac{2}{(q + 1)^2} \sinh \frac{2\alpha}{R^2} \cosh \frac{4\alpha}{R} \left( \frac{n}{R} + \varphi \right). \]

The first three terms are again absorbed in the last one (see [FBV, Lemma 2.1] for details). We are thus left with

\[ \frac{1}{(q + 1)^2} \sinh \frac{2\alpha}{R^2} \sum_{n \geq 2} \cosh \frac{4\alpha}{R} \left( \frac{n}{R} + \varphi \right) \sum_{|x| = n} |f(x)|^2 \]

\[ \geq \frac{1}{(q + 1)^2} \sinh \frac{2\alpha}{R} \cosh \frac{4\alpha^2}{R} \sum_{n \geq 2} \sum_{|x| = n} |f(x)|^2 \]

because of the support property of \( f \).

In summary, if \( R \) is large enough,

\[ \langle [\mathcal{S}, \mathcal{A}] f, f \rangle \geq - \int_0^1 \frac{1}{(q + 1)^2} \sinh \frac{2\alpha}{R} \left( \frac{1}{2R} + \varphi \right) \sum_{|x| = 1} |f(x)|^2 \, dt \]

\[ + \frac{1}{(q + 1)^2} \sinh \frac{2\alpha}{R} \cosh \frac{4\alpha}{R} \int_0^1 \sum_{n \geq 1} \sum_{|x| = n} |f(x)|^2 \, dt \]

as announced. \( \square \)

Even though we need a correction term in order to give the Carleman estimate, we can adapt the argument of the proof of [FBV, Theorem 1.1] to give again a lower bound for solutions of Schrödinger evolutions on trees.

**Theorem 5.7** (Lower bound for solutions of Schrödinger equations). Let \( q \geq 2, A, L, \eta > 0 \) then there exists \( R_0 = R_0(q, A, L) > 0 \) and \( c = c(q, \eta) \) such that

— if \( V \) is a bounded function on \( T \times [0, 1] \) with

\[ \|V\|_\infty = \sup_{t \in [0, 1], x \in T} \{ |V(x, t)| \} \leq L, \]

— and \( u \in C^1([0, 1] : \ell^2(T)) \) is a strong solution of

\[ \partial_t u = i(\mathcal{L} u + V u) \]
that satisfies the bounds

\[ \int_0^1 \sum_{x \in T} |u(x,t)|^2 dt \leq A^2 , \quad \int_{1/2-1/8}^{1/2+1/8} |u(x_0, t)|^2 dt \geq 1 \]

for some \( x_0 \) with \( |x_0| = 2 \).

Then for \( R \geq R_0 \),

\[ \lambda(R) \equiv \left( \int_0^1 \sum_{|R|-1 \leq |x| \leq |R|+1} |u(x,t)|^2 dt \right)^{1/2} \geq ce^{-(1+\eta)R \log R}. \]

**Proof.** For \( \epsilon > 0 \) fixed let us define the following cut-off functions:

— we define \( \theta^R, \mu \) to be \( C^\infty([\mathbb{R}] \) functions such that \( 0 \leq \theta^R, \mu \leq 1 \) and

\[
\theta^R(x) = \begin{cases} 
1, & |x| \leq R - 1 \\
0, & |x| \geq R 
\end{cases}, \quad \mu(x) = \begin{cases} 
1, & |x| \geq \epsilon^{-1} + 1 \\
0, & |x| \leq \epsilon^{-1} 
\end{cases}.
\]

— and a \( C^\infty([0, 1]) \) function \( \varphi \) such that \( 0 \leq \varphi \leq 2 + \epsilon^{-1} \) and

\[
\varphi(t) = \begin{cases} 
2 + \epsilon^{-1}, & t \in \left[\frac{1}{2} - \frac{1}{8}, \frac{1}{2} + \frac{1}{8}\right] \\
0, & t \in \left[0, \frac{1}{4}\right] \cup \left[\frac{3}{4}, 1\right].
\end{cases}
\]

We are going to apply the previous lemma to

\[ g(x, t) := \theta^R(|x|)\mu \left( \frac{|x|}{R} + \varphi(t) \right) u(x, t), \quad x \in T, \quad t \in [0, 1]. \]

Notice that the evolution of \( g \) is given by the expression

\[
(i \partial_t + \mathcal{L})g = \theta^R \mu \left( \frac{|x|}{R} + \varphi \right) (i \partial_t u + \mathcal{L}u) + i \varphi' \theta^R(x) \mu' \left( \frac{|x|}{R} + \varphi \right) u \\
+ \theta^R(x) \frac{1}{q+1} \sum_{y \sim x} \left( \mu \left( \frac{|y|}{R} + \varphi \right) - \mu \left( \frac{|x|}{R} + \varphi \right) \right) u(y, t) \\
+ \frac{1}{q+1} \sum_{y \sim x} (\theta^R(|y|) - \theta^R(|x|)) \mu \left( \frac{|y|}{R} + \varphi \right) u(y, t).
\]
Using the bounds on the cut-off functions and the fact that \(|i\partial_t u + Lu| = |Vu| \leq \|V\|_\infty |u|\) we get

\[
|\langle i\partial_t + L \rangle g| \leq \|V\|_\infty |u| + C_\varphi \left| \mu' \left( \frac{|x|}{R} + \varphi \right) \right| \|u\| + \frac{1}{q + 1} \sum_{y \sim x} \left( \mu \left( \frac{|y|}{R} + \varphi \right) - \mu \left( \frac{|x|}{R} + \varphi \right) \right) |u(y, t)| + \frac{1}{q + 1} \sum_{y \sim x} \left| \theta^R(|y|) - \theta^R(|x|) \right| |u(y, t)|.
\]

Thus, by means of the Carleman estimate with \(\beta = 1/\epsilon\) and \(R\) large enough,

\[
\sinh(2\alpha/R^2) \cosh(4\alpha/\epsilon R) \left| e^{\alpha(\frac{|y|}{R} + \varphi)^2} g 1_{|x| \geq 1} \right|_{L^2_x}^2 
\leq c \|V\|_\infty^2 \left| e^{\alpha(\frac{|y|}{R} + \varphi)^2} g \right|_{L^2_t,y}^2 
+ c \int_0^1 \sum_{n \geq 0, |x| = n} e^{2\alpha(\frac{|y|}{R} + \varphi)^2} \left| \mu' \left( \frac{n}{R} + \varphi \right) \right|^2 |u(x, t)|^2 dt 
+ c \int_0^1 \sum_{n \geq 0, |x| = n} \sum_{y \sim x} e^{2\alpha(\frac{|y|}{R} + \varphi)^2} \left| \mu \left( \frac{|y|}{R} + \varphi \right) - \mu \left( \frac{|x|}{R} + \varphi \right) \right|^2 |u(y, t)|^2 dt 
+ c \int_0^1 \sum_{n \geq 0, |x| = n} \sum_{y \sim x} e^{2\alpha(\frac{|y|}{R} + \varphi)^2} \left| \theta^R(|y|) - \theta^R(|x|) \right| |u(y, t)|^2 dt 
+ \int_0^1 \sinh \frac{4\alpha}{R} \left( \frac{1/2}{R} + \varphi \right) \sum_{|x| = 1} e^{2\alpha(\frac{|x|}{R} + \varphi)^2} |g(x, t)|^2 dt.
\]

Note that we used Cauchy-Schwarz in the third and fourth sums in the form

\[
\left( \sum_{y \sim x} \sum_{y \sim x} \psi(y) \right)^2 \leq (q + 1) \sum_{x \in T} \sum_{y \sim x} |\psi(y)|^2.
\]

We now study carefully the support of each term.

For the first term involving \(V\): by taking \(\alpha = cR \log R\) with \(c \geq \epsilon/2\)

\[
\sinh(2\alpha/R^2) \cosh(4\alpha/\epsilon R) \geq 2cR^{\frac{4\alpha}{\epsilon} - 1} \log R,
\]

so that, when \(R\) large enough (depending on \(L\) also now), the term on the right, up to the term involving root \(o\), is absorbed in the left-hand side. Further, the remaining term is bounded by \(cR^{2\alpha(2+\epsilon^{-1})} L^2 A^2\).
For the term involving the derivative of the function $\mu$, we easily see that $\frac{n}{R} + \varphi \leq 1 + \epsilon^{-1}$, and, therefore

$$
\int_0^1 \sum_{n \geq 0, |x| = n} e^{2\alpha\left(\frac{n}{R} + \varphi\right)^2} \left| \frac{\mu'}{\frac{n}{R} + \varphi} \right|^2 |u(x,t)|^2 \, dt \leq ce^{2\alpha(1+\epsilon^{-1})} A^2.
$$

Next we study the term involving the difference of $\mu$ functions, which is similar to the last one. It is easy to check that if $\frac{n}{R} + \varphi \geq \epsilon^{-1} + 1 + \frac{1}{R}$ both functions $\mu$, the one evaluated at $x$ and the one evaluated at a neighbor of $x$ are 0. Hence,

$$
\int_0^1 \sum_{n \geq 0, |x| = n} \sum_{y \sim x} e^{2\alpha\left(\frac{n}{R} + \varphi\right)^2} \left| \mu\left(\frac{|y|}{R} + \varphi\right) - \mu\left(\frac{|x|}{R} + \varphi\right) \right|^2 |u(y,t)|^2 \, dt
\leq e^{2\alpha(\epsilon^{-1}+1+1/R)} A^2.
$$

Now we focus on the term with difference of $\theta$ functions. In this case, the only possibilities where the difference is not zero are summarize as

1. $|x| = [R] - 1$ and $y$ a future neighbor, $|y| = [R]$.
2. $|x| = [R]$ and $y$ any neighbor of $x$.
3. $|x| = [R] + 1$ and $y$ the past neighbor, $|y| = [R]$.

Thus,

$$
\int_0^1 \sum_{n \geq 0, |x| = n} \sum_{y \sim x} e^{2\alpha\left(\frac{|x|}{R} + \varphi\right)^2} |\theta^R(|y|) - \theta^R(|x|)| |u(y,t)|^2 \, dt
\leq c e^{2\alpha(3+\epsilon^{-1}+1/R)^2} \lambda^2(R).
$$

For the last term in the right-hand side, we just bound the function $\varphi$ to put all the functions out of the sum. Now, by the definition of $\theta^R$ and $\mu$, we see that if $x = x_0$ and $t \in [1/2 - 1/8, 1/2 + 1/8]$ then $\frac{|x_0|}{R} + \varphi e_1 = 2 + \epsilon^{-1} + 2/R$, so the cut-off functions are 1 and $g(x_0,t) = u(x_0,t)$. This allows us to bound the left-hand side of the Carleman inequality of the lemma by

$$
\|e^{\alpha\left(\frac{|x|}{R} + \varphi\right)^2} g1_{|x| \geq 1}\|_{L^2_{x,t}}^2 \geq e^{(2+\epsilon^{-1}+2/R)^2\alpha},
$$

since $\int_{1/2-1/8}^{1/2+1/8} |u(x_0,t)|^2 \, dt \geq 1$. 

Gathering all these results we have,

\[
\sinh \left( \frac{2\alpha}{R^2} \right) \cosh \left( \frac{4\alpha}{\epsilon R} \right) e^{2\alpha(2+\epsilon^{-1}+2/R)^2} \\
\leq e^{2\alpha(2+\epsilon^{-1})} A^2 L^2 + e^{2\alpha(1+\epsilon^{-1}+1/R)^2} A^2 \\
+ \sinh \left( \frac{4\alpha}{R} \left( \frac{1}{2} + 2 + \epsilon^{-1} \right) \right) e^{2\alpha(2+\epsilon^{-1}+1/R)^2} A^2 \\
+ e^{2\alpha(3+\epsilon^{-1}+1/R)^2} \lambda^2(R).
\]

It is clear that the first two terms in the right-hand side are smaller than the third term. Let us see that the third term can be hidden in the left-hand side, for \( R \) large enough, depending on \( A \) (recall that before we showed that \( R \) depends on \( L \) as well) and \( \epsilon \), which is a fixed number. Indeed, taking into account that \( \alpha = c \log R \) with \( c > \frac{\epsilon}{2} \), we have

\[
\sinh \left( \frac{2\alpha}{R^2} \right) \cosh \left( \frac{4\alpha}{\epsilon R} \right) e^{2\alpha(2+\epsilon^{-1}+2/R)^2} \\
\sim 2c \log RR^{2cR(2+\epsilon^{-1})^2+8c(2+\epsilon^{-1})+4\epsilon^{-1}-1+8c/R}
\]

and

\[
\sinh \left( \frac{4\alpha}{R} \left( \frac{1}{2} + 2 + \epsilon^{-1} \right) \right) e^{2\alpha(2+\epsilon^{-1}+1/R)^2} A^2 \\
\sim A^2 R^{2cR(2+\epsilon^{-1})^2+8c(2+\epsilon^{-1})+4c/R},
\]

which proves our claim.

Finally, we conclude that

\[
1 \leq 2c \log RR^{4c^2 \epsilon^{-1}} \leq c e^{(5+2c^{-1})2c \log R -(2+2\epsilon^{-1})2c \log R} \lambda^2(R),
\]

so

\[
\lambda(R) \geq c e^{-(5+2c^{-1})c R \log R+(2+2\epsilon^{-1})c \log R}.
\]

We just finish this result by taking \( c = \epsilon/2 + \epsilon^2 \), to have

\[
\lambda(R) \geq c e^{-(1+9\epsilon/2+5\epsilon^2)R \log R+(1+3\epsilon+2\epsilon^2) \log R}
\]

which is of the desired form. \( \square \)

Once we have the lower bound, since the previous log-convexity properties, \textit{i.e.} Proposition 5.2, derive upper bounds for the term \( \lambda(R) \), we are in position to prove Theorem B from the introduction, that is
Theorem 5.8 (Uniqueness result).
Let \( u \in C^1([0,1] : \ell^2(T)) \) be a solution of (5.23) with \( V \) a bounded potential. If for \( \mu > 1 \)
\[
\sum_{x \in T} e^{2\mu|x| \log(|x|+1)} \left( |u(x,0)|^2 + |u(x,1)|^2 \right) < +\infty,
\]
then \( u \equiv 0 \).

Proof. Let \( \eta > 0 \) be such that \( \mu > 1 + \eta > 1 \). First note that there exists \( x_0 \) such that
\[
a^2 := \int_{1/2-1/8}^{1/2+1/8} |u(x_0,t)|^2 \, dt > 0.
\]
Up to replacing \( u \) by \( u/a \) we may assume that \( a = 1 \). Next, let \( o' \in T \) be such that \( d(o',x_0) = 2 \). As \( e^{2\mu|x| \log(|x|+1)} \sim e^{2\mu d(o',x) \log(d(o',x)+1)} \), we also have
\[
\sum_{x \in T} e^{2\mu d(o',x) \log(d(o',x)+1)} \left( |u(x,0)|^2 + |u(x,1)|^2 \right) < +\infty.
\]
In other words, replacing \( o \) by \( o' \), we may assume that, for some \( x_0 \in T \) with \( |x_0| = 2 \),
\[
\int_{1/2-1/8}^{1/2+1/8} |u(x_0,t)|^2 \, dt \geq 1.
\]
We can then apply the previous theorem to find a lower bound for \( \lambda(R) \). More precisely, we know that \( \lambda(R) \) satisfies (5.36). On the other hand, by Proposition 5.2 we have
\[
\sup_{t \in [0,1]} \sum_{x \in T} |u(x,t)|^2 e^{2\mu|x| \log|x|} < +\infty.
\]
Hence \( \lambda(R) \leq c e^{-\mu R \log R} \). Combining both bounds,
\[
ce^{-\mu R \log R} \geq \lambda(R) \geq c e^{-(1+\eta)R \log R}.
\]
We get a contradiction letting \( R \to \infty \). \( \square \)

Remark 5.9. If one wishes to study the full general problem in the tree
\[
\partial_t u = i(\mathcal{L} u + \mathcal{V} u),
\]
with \( \mathcal{V} u(x) = \sum_{y \in T} V(x,y) u(y) \), a bounded potential seems not enough to conclude uniqueness and some decay or support conditions should be required for \( \mathcal{V} \), since, in order to use the same approach, one needs to study the operator \( \psi \mathcal{V}(\psi^{-1} f) \) for the previous weights.
6. FURTHER COMMENTS

6.1. The choice of Laplace operator. Let \( G = (V, E) \) be an infinite connected graph with finite vertex degree, denoted by \( \deg x \) at each vertex \( x \). There are essentially two ways to define the Laplace operator, the one considered here i.e. the combinatorial Laplacian

\[
L \varphi(x) = \varphi(x) - \frac{1}{\deg x} \sum_{y \sim x} \varphi(y)
\]

and the Laplacian used more commonly in the physics community

\[
\Delta \varphi(x) = (\deg x) \varphi(x) - \sum_{y \sim x} \varphi(y).
\]

In the particular case of regular graphs all vertices have same degree \( d \) and \( \Delta \varphi(x) = dL \varphi(x) \). In particular, if \( u(x, t) \) is a solution of

\[
i \partial_t u(x, t) = Lu(x, t) + V(x, t)u(x, t)
\]

then \( v(x, t) = u(x, dt) \) is a solution of

\[
i \partial_t v(x, t) = \Delta v(x, t) + dV(x, dt)v(x, t).
\]

As the tree \( T_q \) is homogeneous of degree \( d = q + 1 \), our results for the combinatorial Laplacian can therefore be translated into results for the physician Laplacian by replacing time 1 by time \( q + 1 \).

Alternatively, we may adapt the proofs of this paper as has already been noticed in Remark 3.4. We leave to the reader to check that Theorem C is exactly the same for both equations (actually, only the constant \( c \) in (5.34) changes):

**Theorem D** (Uniqueness result). Let \( u \in C^1([0, 1] : \ell^2(T_q)) \) be a solution of

\[
i \partial_t u(x) = \Delta u(x) + V(x)u(x) \text{ with } V \text{ a bounded potential. If for } \mu > 1
\]

\[
\sum_{x \in T_q} e^{2\mu |x| \log(|x|+1)} \left( |u(x, 0)|^2 + |u(x, 1)|^2 \right) < +\infty,
\]

then \( u \equiv 0 \).

6.2. Other infinite graphs. Assume that \( G = (E, V) \) is such that \( L \) has a finitely supported eigenfunction \( e_\lambda : L e_\lambda = \lambda e_\lambda \). In this case, the solution of

\[
i \partial_t u(x, t) = Lu(x, t) + V(x, t)u(x, t), \; u(x, 0) = e_\lambda(x)
\]

is given by \( u(x, t) = e^{-i\lambda t} e_\lambda(x) \). This solution is thus finitely supported at all times. In particular, no analogue of Theorems A and C can hold.

Examples of graphs where this may happen are the Diestel-Leader graphs introduced in [DL]. Recall that those are defined as follows:
Definition 6.1. Let $q, r \geq 2$. In $T_q$ (resp. $T_r$) we fix a geodesic ray $\omega$ (resp. $\omega'$) and write $h = h_\omega$ (resp. $h = h_{\omega'}$) for the associated Busemann function. The Diestel-Leader graph $DL(p, q)$ is

$$DL(q, r) = \{(x, y) \in T_q \times T_r : h(x) + h(y) = 0\}$$

and neighbourhood is given by $(x, y) \sim (x', y')$ if $x \sim x'$ and $y \sim y'$.

This graph is regular of degree $q + r$. Bartholdi and Woess [BW, Theorem 3.15] have shown that $L^2(DL(q, r))$ has an orthonormal basis of finitely supported eigenfunctions of $\mathcal{L}$.

Quint [Qu] and Taplyaev [Te] have respectively shown that on the Pascal graph and the Sierpiński graphs there also exists finitely supported eigenfunctions of $\mathcal{L}$. Of course, on trees, there are no non-zero finitely supported eigenfunctions of the Laplacian.

Let us now turn to non-homogeneous trees and prove the following:

Proposition 6.2. Let $(\omega_n)$ be a sequence of positive real numbers with $\omega_n \to 0$. Then there exists a rooted tree $T$ such that $\mathcal{L}$ has an eigenvector with $|e(x)| \leq C\omega_{|x|}$ for some $C > 0$. In particular, if $u$ is the solution of

$$i\partial_t u(x, t) = \mathcal{L}u(x, t), \quad u(x, 0) = e(x)$$

then $|u(x, t)| \leq C\omega_{|x|}$ for every $t \geq 0$.

Remark 6.3. This does not mean that if $\tilde{\omega}_n = o(\omega_n)$ and $u$ is a solution of $i\partial_t u(x, t) = \mathcal{L}u(x, t)$ such that $|u(x, t_i)| = O(\tilde{\omega}_n)$ at times $t_0 = 0$ and $t_1 = 1$ then $u = 0$.

For instance, for the homogeneous tree $T_q$, the construction below provides us with an eigenvector satisfying $|e(x)| \lesssim q^{-|x|/2}$, i.e. $\omega_n = q^{-n/2}$. On the other hand, Corollary B shows that the optimal decrease rate at which the only solution is 0 is $\tilde{\omega}_n = o\left(\frac{1}{\sqrt{n}} \left(\frac{e}{2(q + 1)n}\right)^n\right)$.

For the trees constructed below, we do not know what the maximal rate of decrease is.

Proof. The tree we consider is a rapidly branching tree as introduced by Fujiwara [Fu]. Let $d_n$ be a sequence of integers with $d_n \geq 2$ and construct the tree recursively. We start with the root $o$. We link $o$ to $d_0$ vertices. Each of these vertices is then linked to $d_1 - 1$ further vertices,... We thus construct a tree such the vertices at distance $n$ from the root have degree $d_n$.

Next, we look for a radial eigenvector $e$ of $\mathcal{L}$ with eigenvalue 1. For simplicity of notation, we write $e(x) = e(|x|)$. Those are constructed in
but for sake of completeness, we reproduce the construction here. Then, $\mathcal{L}e(x) = e(x)$ reads

- if $x = 0$, $e(0) - e(1) = e(0)$ thus $e(1) = 0$
- if $|x| = n \geq 1$, $e(n) - \frac{1}{d_n}(e(n - 1) + (d_n - 1)e(n + 1)) = e(n)$ thus $e(n + 1) = -\frac{1}{d_n - 1}e(n - 1)$.

It follows that $e(n) = 0$ if $n$ is odd and, if $n = 2p \geq 2$,

$$e(2p) = (-1)^p \left( \prod_{k=1}^{p} \frac{1}{d_{2k-1} - 1} \right) e(0).$$

It is then easy to inductively construct the $d_{2k-1}$’s in order to have $\prod_{k=1}^{p}(d_{2k-1} - 1) \geq \omega_{2n}^{-1}$ and the corresponding $e$ is the eigenvector we are looking for. □

ACKNOWLEDGMENTS

The first author kindly acknowledge financial support from the IdEx postdoctoral program via the PDEUC project.

The second author kindly acknowledge financial support from the French ANR program, ANR-12-BS01-0001 (Aventures), the French-Tunisian CMCU/UTIQUE project 32701UB Popart.

Both authors acknowledge the financial support of the Austrian-French AMADEUS project 35598VB - ChargeDisq.

This study has been carried out with financial support from the French State, managed by the French National Research Agency (ANR) in the frame of the Investments for the Future Program IdEx Bordeaux - CPU (ANR-10-IDEX-03-02).
