ABSTRACT

The regional exponential reduced observability concept in the presence for linear dynamical systems is addressed for a class of distributed parameter systems governed by strongly continuous semi group in Hilbert space. Thus, the existence of necessary and sufficient conditions is established for regional exponential reduced estimator in parabolic infinite dimensional systems. More precisely, the introduced approach is developed by using the decomposed system and reduced system in connection with various new concepts of (stability, detectability, estimator, observability and strategic sensors).

Finally, we also show that there exists a dynamical system for two-phase exchange system described by the coupled parabolic equations is not exponentially reduced observable in usual sense, but it may be regionally exponentially reduced observable.

Keywords: $\omega_E^X$-observability; $\omega_E^X$-detectability; $\omega_E^X$-strategic sensor; $\omega_E^X$- detectability; exchange system.

1. INTRODUCTION

One of the most important concepts in infinite dimensional systems analysis is observability concept. Many researches of these concept included the notion of exponential observer (estimator), where Luenberger introduced this notion for finite dimensional systems [22], and has been generalized to infinite dimensional systems described by strongly continuous linear semi-group operators by Gressang and Lamont [20]. The purpose of an exponential estimator is to provide an exponential state estimation for the considered system state [16]. New concept of regional analysis for a class of distributed parameter systems was extended by Al-Saphory and El Jai et al. as in ref.s [1-7, 18, 16, 25-29]. Various asymptotic characterizations have been established and explored in connection with sensors structures [1, 6]. In this paper, we introduce and study the notion of exponential regional reduced state observability in a given region \( \omega \) of the domain \( \Omega \). Thus the developed approach is an extension of previous works to the regional case as in [2]. Moreover the relationship between this notion, regional detectability and strategic sensors are studied and discussed. The main reason behind the study of this notion (reduced observability), there exist some problem in the real world cannot observe the system state in the whole domain, but in a part of this domain. The scenario described by (Figure 1) below, one is interested in estimating the state in the green zone rather than in the entire space [12]. This problem falls into a class of so-called regional observation and estimation problem introduced by Al-Saphory and El-Jai and their workers as in [1-7, 25-29].

![Fig 1: Zone control \( \mathcal{R} \) with fixed and mobile sensors](image)

This paper is organized as follows. Section 2 is devoted to the introduction of regional exponential detectability and considered system with \( \omega \)-detectability and \( \omega \)-observability. We study the links of this notion with the regional exponential observability and strategic sensors. In Section 3, we study a regional exponential observability through the relations between \( \omega \)-estimator reconstruction method and \( \omega \)-observability. In section 4 we introduce regional exponential reduced observability notion for a distributed parameter system in terms of regional exponential reduced detectability and reduced strategic sensors. In the last section, we illustrate applications with different domains and circular strategic sensors of two-phase exchange systems.

2. REGIONAL EXPONENTIAL DETECTABILITY

The detectability is in some sense a dual notion of stabilizability [15]. This notion was considered and studied in the whole domain.

2.1 Considered Systems

Let \( \Omega \) be a bounded and open subset of \( \mathbb{R}^n \), with boundary \( \partial \Omega \). Let \([0, T], T > 0 \) a time measurement interval and \( \omega \) be a non-empty given subregion of \( \Omega \). We denote \( Q = \Omega \times (0, \infty) \) and \( \Theta = \partial \Omega \times (0, \infty) \). Let \( X, U \), and \( \Theta \) be separable Hilbert spaces, where \( X \) is the state space, \( U \) the control space and \( \Theta \) the observation space. We consider \( X = L^2(\Omega), U = L^2(\partial \Omega, R^p) \) and \( \Theta = L^2(0, \infty, R^q) \) where \( p \) and \( q \) hold for the number of actuators and sensors [17]. The considered distributed parameter systems are described by the following parabolic equations

\[
\left\{
\begin{array}{l}
\frac{\partial x}{\partial t}(\xi, t) = Ax(\xi, t) + Bu(t) \\
x(\eta, t) = 0 \\
x(\xi, 0) = x_0(\xi) \\
y(., t) = Cx(., t)
\end{array}
\right.
\]  

(1) augmented with the output function

\[
y(., t) = Cx(., t)
\]  

(2)

where \( A \) is a second-order linear differential operator, which generates a strongly continuous semigroup \( (S_t(t))_{t \geq 0} \) on the Hilbert space \( X = L^2(\Omega) \), and is self-adjoint with compact resolvent. The operators \( B \in L(R^p, X) \) and \( C \in L(X, R^q) \) depend on the structures of actuators and sensors [17] see (Figure 2).

![Fig 2: System representation](image)
That means, in the case of pointwise (internal or boundary) and boundary zone sensors (actuators), we have $B \notin \mathcal{L}(R^p, X)$ and $C \notin \mathcal{L}(X, R^q)$ [12, 22]. Thus, the system (1) has a unique solution given by
\[
x(\xi, t) = S_A(t)x_0(\xi) + \int_0^t S_A(t - r)Bu(r)dr.
\] (3)

The problem is that how to give an approach which enable to estimate the system state in a sub-region $\omega$. The regional exponential reduced estimator is defined when the output give a part of the state vector in this region.

### 2.2 Definitions and Characterizations

We extend some definitions and characterizations in the Hilbert space $L^2(\Omega)$ as ref.s [15, 19].

**Definition 2.1:** The semi-group $(S_A(t))_{t \geq 0}$ is said to be exponential stable on $\Omega$ or $(\Omega_e$-stable) if there exist two positive constants $M$ and $\alpha$ such that
\[
\|S_A(t)\|_{L^2(\Omega)} \leq Me^{-\alpha t}; \quad t \geq 0
\] (4)

If $(S_A(t))_{t \geq 0}$ is an $(\Omega_e$-stable semi-group, then for all $x_0(.) \in X$, the solution of the associated autonomous system satisfies
\[
\|x(., t)\|_{L^2(\Omega)} = \|S_A(t)x_0(.)\|_{L^2(\Omega)} \leq Me^{-\alpha t}\|x_0(.)\|_{L^2(\Omega)},
\]
and therefore
\[
\lim_{t \to \infty} \|x(., t)\|_{L^2(\Omega)} = \lim_{t \to \infty} \|S_A(t)x_0(.)\|_{L^2(\Omega)} = 0.
\]

we shall consider the following usual definition of stability.

**Definition 2.2:** The system (1) is said to be $\Omega_e$-stable if the operator $A$ generates a semi-group which is $\Omega_e$-stable.

**Definition 2.3:** The system (1) together with the output (2) is said to be detectable on $\Omega$ if there exists an operator $H : R^q \to L^2(\Omega)$ such that $(A - HC)$ generates a strongly continuous semi-group $(S_A(t))_{t \geq 0}$ which is $\Omega_e$-stable.

Thus, if a system is ($\Omega_e$-detectable), then it is possible to construct an exponential $\Omega$-estimator for the system state [9].

**Remark 2.4:** In this paper, we only need the relation (4) to be true on a given subdomain $\omega \subset \Omega$, i.e., if we consider a subdomain $\omega$ of the domain $\Omega$ and let $x_\omega$ be the function defined by
\[
x_\omega : L^2(\Omega) \to L^2(\omega)
\] (5)

where $x|_{\omega}$ is the restriction of $x$ to $\omega$. Thus
\[
\|x_\omega S_A(t)\|_{L^2(\omega)} \leq Me^{-\alpha t}; \quad t \geq 0.
\] (6)

and then
\[
\lim_{t \to \infty} \|x(., t)\|_{L^2(\omega)} = 0.
\]

We may refer to this as regional exponential stability (or $\omega_e$-stability), which is the equivalent for the considered class of systems to the exponential stability.

**Definition 2.5:** The system (1) is said to be regionally $\omega_e$-stable if the operator $A$ generates a semi-group which is $\omega_e$-stable.

In this section, we shall extend the definition of detectability by using equation (5) to the regional case by considering $\omega$ as subregion of $\Omega$. 

---

**Fig. 2:** The domain of $\Omega$, the sub-region $\omega$, various sensors locations.
Definition 2.6: The system (1)-(2) is said to be \( \omega_E \)-detectable if there exists an operator \( H_\omega : R^q \to L^2(\omega) \) such that \( (A - H_\omega C) \) generates a strongly continuous semi-group \( \{S_{h_\omega}(t)\}_{t \geq 0} \) which is \( \omega_E \)-stable.

The main reason for introducing the concept of \( \omega_E \)-detectability is the possibility of constructing an \( \omega_E \)-estimator for the state of system (1).

2.3 \( \omega_E \)-Detectability and \( \omega \)-Observability

It has been shown that a system which is exactly observable is detectable [16]. For linear systems, we recall the \( \omega_E \)-observability [2]. Now consider the autonomous system of (1) by the following form

\[
\begin{align*}
\frac{dx}{dt} &= Ax(x, t) \\ x(\eta, t) &= 0 \\ x(\xi, 0) &= x_0(\xi)
\end{align*}
\]

where \( x(. , 0) \) is supposed to be unknown. The knowledge of \( x(., 0) \) allows one to observe the state \( x(t, 0) \) at any time \( t \). Measurements are obtained by the output function (2). The solution of the system (6) is given by:

\[ x(t, 0) = S_x(t)x(., 0). \]  

Now define the operator:

\[ K : x \in X \to Kx = CS_x(t)x \in O, \]

then \( y(t, \cdot) = K(t)x(., 0) \). We denote by \( K^* : O \to X \) the adjoint of \( K \), and then, it is given by

\[ K^* y^* = \int_0^t S_x^*(s)C'y'ds \]  

- The system (6)-(2) is said to be exactly \( \omega \)-observable if

\[ \text{Im} X_\omega K^* = L^2(\omega) \]

- The system (6)-(2) is said to be weakly \( \omega \)-observable if

\[ \text{Im} X_\omega K^* = L^2(\omega) \]

- If the system (6)-(2) is weakly \( \omega \)-observable, then \( x(. , 0) \) is given by

\[ x_0 = (K^* K)^{-1}K^* y = K^+ y, \]

where \( K^+ \) is the pseudo-inverse of the operator \( K \) [15, 25]. These definitions have been extended to regional boundary case for parabolic, hyperbolic in [26-28] linear, semi-linear and nonlinear [10-11, 29]. However, we can introduce the following important result.

Corollary 2.7: If the system (1)-(2) is exactly \( \omega \)-observable, then it is \( \omega_E \)-detectable. This result allows

\[ \exists \gamma > 0 \text{ such that } \|x_\omega x\|_{L^2(\omega)} \leq \gamma \|CS_x(.)x_0\|_{L^2(O, \omega, D)} \forall x \in L^2(\omega). \]  

Proof: We conclude the proof of this corollary from the results on observability considering \( X_\omega K^* \)[14]. We have the following forms:

(a) \( \text{Im} F \subset \text{Im} G \)

(b) There exist \( \gamma > 0 \) such that \( \|F^* x^*\|_P \leq \gamma \|G^* x^*\|_Q, \forall x^* \in V^* \).

From the right hand side of this relation \( \exists M, \alpha > 0 \) with \( \gamma < M \) such that

\[ \gamma \|G^* x^*\|_Q \leq Me^{-\alpha t} \|x^*\|_P. \]

where \( P, Q \) and \( V \) be Banach reflexive space and \( F \in L(P, V), G \in L(U, V) \).

Now, Let \( P = V = L^2(\omega), U = 0, F = I \) to \( L^2(\omega) \) and \( G = S_x^*(.) X^\omega C^* \) where \( S_x(.) \) is a strongly continuous semi group generates by \( A \), which is \( \omega_E \)-stable then, it is \( \omega_E \)-detectable.

As in El Jai and Pritchard [17], we will develop a characterization result that links the \( \omega_E \)-detectability in terms of sensors structures. So, we recall some definitions related to sensors.

- A sensor is defined by any couple \( (D, f) \) where \( D \) a non-empty closed subset of \( \Omega \), is the spatial support of the sensor, and \( f \in L^2(D) \) defines the spatial distribution of the sensing measurements on \( D \).
In the case of a pointwise sensor, $D$ is reduced to a point $(b)$ and $f = \delta(-b)$, where $D$ is the Dirac mass concentrated in $b$. Depending on the choice of the parameters $D$ and $f$ we have various types of sensors, the output function (2) may be written in the form

$$ y(t) = \int_B x(\xi, t)f(\xi)d\xi \quad \text{(zone case)} $$

$$ y(t) = \int_B x(\xi, t)\delta(\xi - b)d\xi = x(b, t) \quad \text{(pointwise case)} $$

In the case of boundary measurements (pointwise or zone) the support of sensors $D$ is subset of $\partial \Omega$. Then, the output function (2) given by

$$ y(t) = \int_B \frac{\partial}{\partial \nu}(\xi, t)\delta(\xi - b)d\xi \quad \text{(Boundary pointwise case)} \quad (12) $$

Now in the case where the zone measurements, with $D = \Gamma \subset \partial \Omega$ and $f \in L^2(\Gamma')$. Then, the output function (2) given by

$$ y(t) = \int_B \frac{\partial}{\partial \nu}(\xi, t)f(\xi)d\xi \quad \text{(boundary zone case)} \quad (13) $$

- The sensors (zone or pointwise) $(D_i, f_i)_{1 \leq i \leq q}$ are said to be $\omega$-strategic sensors if the system (1)-(2) is weakly $\omega$-observable.

Let us consider the set $(\varphi, \omega)$ of orthonormal functions in $L^2(\omega)$ associated with the eigenvalues $\lambda_n$ of multiplicity $r_n$ [15] and suppose that the system (1) has $J$ unstable modes. We have the following characterization of $\omega\gamma$-detectability in the terms of the structure sensors.

**Proposition 2.8:** Suppose that there are $q$ zone sensors $(D_i, f_i)_{1 \leq i \leq q}$. If

1. $q \geq r$
2. $\text{Rank} \, G_n = r_n \, \forall n, \, n = 1, \ldots, J$
   
   with $G = (G_n)_{ij} = (\varphi_{h_i}, f_i)_{L^2(\Omega_j)}\text{where}\, \sup_n r_n = r < \infty$ and $j = 1, \ldots, r_n$.

Then the system (1)-(2) is $\omega\gamma$-detectable.

**Proof:** By the result on observability considering $\chi_\omega K'$ [14], we can proof this theorem. We see that if the system is satisfy the condition (2) above. Since $\text{Rank} \, G_n = r_n$, therefore, the sensor of the system (1)-(2) is strategic sensor, and this system (1)-(2) is weakly $\omega$-observable, then it’s exactly $\omega$-observable, finally we have the system (1)-(2) is $\omega\gamma$-detectable.

### 3. REGIONAL EXPONENTIAL OBSERVABILITY

In this section, we give an approach which allows constructing an $\omega$-estimator of $T x(\xi, t)$. This method avoids the calculation of the inverse operators, and the consideration of the initial state [18]. It enables to observe the current state in $\omega$ without needing the effect of the initial state of the original system.

#### 3.1 $\omega\gamma$-Estimator Reconstruction Method

We consider the system and the output specified by the following form:

$$
\begin{align*}
\frac{\partial x}{\partial t}(\xi, t) &= Ax(\xi, t) + Bu(t) \\
x(\eta, t) &= 0 \\
x(\xi, 0) &= x_0(\xi) \\
y(\cdot, t) &= Cx(\cdot, t)
\end{align*}
$$

Let $\omega \subset \Omega$ be a given subdomain (region) of $\Omega$ and assume that for $T \in L(L^2(\Omega))$, and $T = \chi_\omega T$ (where $\chi_\omega$ is defined in (5)) there exists a system with state $x(\cdot, t)$ such that

$$ z(\xi, t) = T x(\xi, t). \quad (15) $$

Thus, if we can build a system which is an exponential estimator for $z(\xi, t)$, then it will also be an exponential estimator for $T x(\cdot, t)$, that is to say an exponential estimator to the restriction of $T x(\cdot, t)$ to the region $\omega$. The equations (2)-(15) give

$$ [yz] = [C] z \quad (16) $$

If we assume that there exist two linear bounded operators $R$ and $S$, where $R: L^\infty(\omega) \Rightarrow L^2(\omega)$ and $S: L^2(\omega) \Rightarrow L^2(\omega)$, such that $RC + ST = I$, then by deriving $z(\xi, t)$ we have

$$ \frac{\partial z}{\partial t}(\xi, t) = \hat{T} \frac{\partial x}{\partial t}(\xi, t) = \hat{T} Ax(\xi, t) + \hat{T} Bu(t) $$

$$ = \hat{T} Asx(\xi, t) + \hat{T} ARy(\cdot, t) + \hat{T} Bu(t). $$

Consider now the system (which is destined to be the maximal $\omega\gamma$-estimator for $z$)
\[
\begin{align*}
\frac{\partial \tilde{z}}{\partial t}(\xi, t) &= F_\omega \tilde{z}(\xi, t) + G_\omega u(t) + H_\omega y(., t) & \Omega \\
\tilde{z}(\eta, t) &= 0 & \Theta \\
\tilde{z}(\xi, 0) &= \tilde{z}_0(\xi) & \Omega
\end{align*}
\]

where \(F_\omega\) generates a strongly continuous semi-group \((S_{F_\omega}(t))_{t \geq 0}\) which is regionally exponentially stable on \(X = L^2(\omega)\), i.e., \(3M_{F_\omega}, \omega \in \mathbb{R}\) such that
\[
\|X_\omega S_{F_\omega}(\cdot)\|_{L^2(\omega)} \leq M_{F_\omega} e^{-\alpha \tau}, \forall \tau \geq 0.
\]
and \(G_\omega \in \mathcal{L}(R^P, L^2(\omega))\) and \(H_\omega \in \mathcal{L}(R^Q, L^2(\omega))\). The solution of (17) is given by
\[
\tilde{z}(., t) = S_{F_\omega}(t)\tilde{z}_0(\cdot) + \int_0^t S_{F_\omega}(t - \tau) [G_\omega u(\tau) + H_\omega y(., \tau)] d\tau
\]

3.2 \(\omega_E^r\)-Observability

In this case, we consider \(F = I\), and \(X = Z\), so the operator equation \(\dot{X} = F_\omega X + H_\omega C\) of the \(\omega\)-observable reduces to \(F_\omega = A - H_\omega C\), where \(A\) and \(C\) are known. Thus, the operator \(H_\omega\) must be determined such that the operator \(F_\omega\) is \(\omega_E\)-stable. For the system (14), consider the dynamic system
\[
\begin{align*}
\frac{\partial \tilde{z}}{\partial t}(\xi, t) &= A\tilde{z}(\xi, t) + Bu(t) + H_\omega (y(., t)) - \mathcal{L}\tilde{z}(\xi, t) & \Omega \\
\tilde{z}(\eta, t) &= 0 & \Theta \\
\tilde{z}(\xi, 0) &= \tilde{z}_0(\xi) & \Omega
\end{align*}
\]

Thus, a sufficient condition for existence of \(\omega_E\)-estimator is formulated in the following proposition.

**Proposition 3.1:** Suppose that the system (1)-(2) is \(\omega_E\)-detectable, and then the dynamical system (20) achieve the \(\omega_E\)-observability for the system (1)-(2), i.e.
\[
\lim_{t \to \infty} \|x(\xi, t) - \tilde{z}(\xi, t)\|_{L^2(\omega)} = 0.
\]

**Proof:** By the same way with minor modifications as in ref. R. Al-Saphory [2] we can prove the proposition 3.1 in different case of sensors (zone, pointwise) internal or boundary.

4. REGIONAL REDUCED EXPONENTIAL OBSERVABILITY

In this section we need some of additional assumptions, concerning the semigroup, its infinitesimal generator, and the observation space, under which condition can be given a regional reduced estimator for the state system (1)-(2).

4.1 General Decomposed System

Now, under the assumption of strongly continuous semigroup we have the system (1)-(2) is reduced as in the additional assumptions allow a decomposition of (1) to a form of the stabilizing operator \(H\). These assumptions are as follows.

1. \(A\) has a pure point spectrum, denoted by \(\sigma(A)\).
2. \(S_X(t)\) is a compact operator for some \(t > 0\)
3. For \(\delta > 0\), \(\sigma(A)\) the spectrum of \(A\) contained in the closed half plane \(\{\lambda: Re \lambda \leq -\delta\}\).
4. The subspace associated with each finite dimensional point of \(\sigma(A)\) in the half plane \(\{\lambda: Re \lambda \geq -\delta\}\).
5. \(\sigma(A)\) is finite dimensional.

These five assumptions are strong. The Hille-Yosida theorem implies that the set of spectral point of \(A\) lying in the half plane \(\{\lambda: Re \lambda \geq -\delta\}\) forms a bounded spectral set. Denote this spectral set by \(\sigma(A_1)\). Using the spectral set \(\sigma(A_2)\), a reduced form of (1) can be derived. Denote \(\sigma(A) - \sigma(A_1)\) by \(\sigma(A_2)\). As \(A\) is a closed operator with nonempty resolvent set, operational calculus can be used to completely reduce the operator \(A\) in terms of the spectral sets \(\sigma(A_1)\) and \(\sigma(A_2)\) [20]. \(\sigma(A_1)\) and \(\sigma(A_2)\) determine subspaces \(X_1\) and \(X_2\)
\[
X = X_1 \oplus X_2
\]

and projections \(E_1: X \to X_1, E_2: X \to X_2\), such that
\[
E_1Ax = AE_1x \quad E_2Ax = AE_2x
\]

Defining \(A_1x = AE_1x, D(A_1) = D(A) \cap X_1\) and \(A_2x = AE_2x, D(A_2) = D(A) \cap X_2\)
the operator \(A\) can be represented by
\[
Ax = \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix} [x_1] \quad \text{and } \theta = \begin{bmatrix} P_1 \\ B_2 \end{bmatrix}
\]

(22)
Where \( x = x_1 + x_2 \),

\[
x \in D(A), x_1 \in D(A_1), x_2 \in D(A_2), B_1 \in \mathcal{L}(\mathbb{R}^p, X_1) \text{ and } B_2 \in \mathcal{L}(\mathbb{R}^p, X_2)
\]
as \( D(A) \) is dense in \( X \), \( D(A_1) \) is dense in \( X_1 \), and \( D(A_2) \) is dense in \( X_2 \).

\( A_1 \) and \( A_2 \) are closed operators as \( A \) is closed operator. If \( A \) is the infinitesimal generator of a strongly continuous semigroup, then the Hilfle-Yosida theorem shows that both \( A_1 \) and \( A_2 \) are infinitesimal generators. Using the decomposition of \( X \) and \( A \) given by (21)-(22), and then (1)-(2) can be rewritten in the following forms [20]

\[
\begin{align*}
\frac{\partial x}{\partial t}(\xi, t) &= A_1 x_1(\xi, t) + E_1 B_1 u(t) \\
x_1(\eta, t) &= 0 \\
x_1(\xi, 0) &= x_{1_0}(\xi)
\end{align*}
\]

and

\[
\begin{align*}
\frac{\partial x}{\partial t}(\xi, t) &= A_2 x_2(\xi, t) + E_2 B_2 u(t) \\
x_2(\eta, t) &= 0 \\
x_2(\xi, 0) &= x_{2_0}(\xi)
\end{align*}
\]

Augmented with the output function

\[
y(\cdot, t) = C x(\xi, t) \tag{25}
\]

Equations (24)-(25) are called the reduced form of (1)-(2).

Since \( A_1 \) is the restriction of \( A \) to \( X_1 \), and \( D(A_2) = D(A) \cap X_1 \), the spectrum of \( A_1 \) is \( \sigma(A_2) \) [21]. As the points of \( \sigma(A_1) \) are isolated, each point by itself is a spectral set, and the spectral sets so formed are pairwise disjoint. Thus a projection \( E_1 \) and subspace \( X_1 \) can be associated with each point \( \lambda \epsilon \sigma(A_1) \) and the subspace \( X_1 \) completely reduced to

\[
X_1 = X_{11} \oplus X_{12} \oplus \ldots \oplus X_{1n}
\]

where \( n \) is the number of points in \( \sigma(A_1) \). Each \( X_i \) is finite dimensional by assumption, hence \( X_1 \) is finite dimensional, and \( A_1 \) is a bounded operator. Then choosing bases for \( X_1 \) and \( \Omega \), (24) can be represented as a linear constant coefficient ordinary differential equation, and \( C \) restricted to \( X_1 \) can be expressed as a matrix.

In terms of the finite dimensional bases for \( X_1 \) and \( \Omega \), the homogeneous equations corresponding to (24)-(25) are

\[
\begin{align*}
\frac{\partial x_1}{\partial t}(\xi, t) &= A_1 x_1(\xi, t) \\
x_1(\xi, 0) &= x_{1_0}(\xi) \\
\frac{\partial x_2}{\partial t}(\xi, t) &= A_2 x_2(\xi, t) \\
x_2(\xi, 0) &= x_{2_0}(\xi)
\end{align*}
\]

\[
y(\cdot, t) = C x(\xi, t) \tag{28}
\]

Where \( \mathcal{P} \) is the coordinate space associated with the basis for \( X_1 \), and \( \mathcal{C}: X_1 \rightarrow \mathcal{O} \) in terms of the bases of \( X_1 \) and \( \Omega \).

An estimate will now be made of the solutions of (28). A having a pure point spectrum implies that \( A_2 \) has a pure point spectrum, while for any \( \gamma > 0 \) implies that \( S_{A_2}(t) \) is a compact operator. As \( S_{A_2}(t) \) is a compact operator, its spectrum consists of only point spectrum, denoted by \( \mathcal{P} \sigma(S_{A_2}(t)) \) is given by

\[
e^{\mathcal{P} \sigma(A_2) t}, \quad \text{as } \Re \sigma(A_2) \leq -\delta, \quad \|e^{\mathcal{P} \sigma(A_2) t}\| \leq e^{-\delta t}
\]

Then the spectral radius of \( S_{A_2}(t) \) satisfies

\[
r_\mathcal{P}(S_{A_2}(t)) \leq e^{-\delta t}
\]

using a lemma of Hale [18]. For any \( \gamma > 0 \) there exists an \( M(\gamma) \geq 1 \) such that

\[
\|S_{A_2}(t)x_2\| \leq M(x_{1_0})e^{(-\delta + \gamma)t}\|x_{2_0}\|
\]

for all \( t \geq 0 \) and \( x_{2_0} \in X_2 \). Thus, (27) is exponentially stable.

### 4.2 General Reduced System

In the case where the output function (2) gives information about a part of the state vector \( x(\xi, t) \), it is necessary to define an exponential estimator enables to construct the unknown part of the state. Consider now \( X = X_1 \oplus X_2 \) where \( X_1 \) and \( X_2 \) are subspaces of \( X \). Under the hypothesis of subsection 4.1, the system (1) can be decomposed [16, 20] by
where \( x_1 \in X_1, x_2 \in X_2, B_1 \in \mathcal{L}(X_1, U) \) and \( B_2 \in \mathcal{L}(X_2, U) \). Using the decomposition above, the system (1) can be written by the form
\[
\begin{aligned}
\dot{x}_1(\xi, t) &= A_{11} x_1(\xi, t) + A_{12} x_2(\xi, t) + B_1 u(t) & Q \\
x_1(\eta, t) &= 0 & \Theta \\
(x_1, 0) &= x_{01}(\xi) & \Omega
\end{aligned}
\] (29)

and
\[
\begin{aligned}
\dot{x}_2(\xi, t) &= A_{21} x_1(\xi, t) + A_{22} x_2(\xi, t) + B_2 u(t) & Q \\
x_2(\eta, t) &= 0 & \Theta \\
(x_2, 0) &= x_{02}(\xi) & \Omega
\end{aligned}
\] (30)

augmented with the output function
\[
y(., t) = C x_1(\xi, t) \quad (31)
\]

where \( y(., t) = x_1(\xi, t) \oplus x_2(\xi, t) \). The problem consists in constructing a regional exponential estimator that enables one to estimate the unknown part \( x_2(\xi, t) \) equivalently; the problem is reduced to define the dynamical system for (31). Thus, equations (30)-(31) allow the following system:
\[
\begin{aligned}
\dot{a}(\xi, t) &= A_{22} a(\xi, t) + [B_2 u(t) + A_{21} y(., t)] & Q \\
a(\eta, t) &= 0 & \Theta \\
a(0, t) &= a_0(\xi) & \Omega
\end{aligned}
\] (32)

with the output function
\[
y(., t) = A_{12} a(., t) \quad (33)
\]

where the state \( a \) in system (32) plays the role of the state \( x_2 \) in system (30).

### 4.3 Regional Reduced Observability and \( \omega_{ER} \)-Detectability

As in previous section 2 we can extend these results to the case of regional reduced ordered system for regional observability and \( \omega_{ER} \)-detectability. In this case, the equation (8) it can be given by define the following operator
\[
\mathcal{K}: x_2 \in X_2 \rightarrow \mathcal{K} x_2 = A_{12} S_{A_{12}}(t) x_2 \in \mathcal{O}, \text{ then } y(., t) = \mathcal{K}(t) x_2(., \cdot), \text{ with the adjoint } \mathcal{K}^*: \mathcal{O} \rightarrow X_2 \text{ such that }
\]
\[
\mathcal{K}^* y(., t) = \int_0^t S^*(s) A_{12} y(., s) ds.
\]

Let \( \omega \in \Omega \) and \( \mathcal{X}_\omega: L^2(\Omega) \rightarrow L^2(\omega) = X_2, x_2 \rightarrow \mathcal{X}_\omega = x_{2|\omega} \)

where \( x_{2|\omega} \) is the restriction of the state \( x_2 \) to \( \omega \).

**Definition 4.1**: The system (32)-(33) is called exactly regionally reduced-observable (or exactly \( \omega_{ER} \)-observable) if
\[
\text{Im} \mathcal{X}_\omega \mathcal{K}^* = L^2(\omega) = X_2
\]

**Definition 4.2**: The system (32)-(33) is called weakly regionally reduced-observable (or weakly \( \omega_{ER} \)-observable) if
\[
\text{Im} \mathcal{X}_\omega \mathcal{K}^* = L^2(\omega) = X_2
\]

**Definition 4.3**: The suite of sensors (zone or pointwise) \( (D_r, f_r)_{1 \leq r \leq n} \) are called regional reduced strategic sensors (or \( \omega_{ER} \)-strategic sensors if the system (32)-(33) is weakly \( \omega_{ER} \)-observable.

**Definition 4.4**: The semi-group \( (S_{A_{12}}(t))_{t \geq 0} \) is said to be exponential reduced stable (or \( \Omega_{ER} \)-stable) if \( \exists M, \alpha > 0 \) such that
\[ \| S_{i22}(t) \|_{L^2(\Omega)} \leq M_{i22} e^{-\alpha_{i22}(t)}, t \geq 0 \] (34)

**Definition 4.5:** Let \((S_{i22}(t))_{t \geq 0}\) be an \(\Omega_{ER}\)-stable semi-group, then \(\forall x_2 \in X_2\) the solution of the associated autonomous system satisfies:

\[ \| x_2(., t) \|_{L^2(\Omega)} = \| S_{i22}(t)x_2(., t) \|_{L^2(\Omega)} \leq M_{i22} e^{-\alpha_{i22}(t)} \| x_2(., t) \|_{L^2(\Omega)} \]

and therefore

\[ \lim_{t \to 0} \| x_2(., t) \|_{L^2(\Omega)} = \lim_{t \to 0} \| S_{i22}(t)x_2(., t) \|_{L^2(\Omega)} = 0 \]

**Definition 4.6:** The system \((32)\) is said to be \(\Omega_{ER}\)-stable if the operator \(A_{i22}\) generates a semi-group which is \(\Omega_{ER}\)-stable.

**Definition 4.7:** The system \((32)-(33)\) is said to be exponential reduced detectable on \(\Omega\) (or \(\Omega_{ER}\)-detectable) if there exists a bounded operator \(H: R^q \to L^2(\Omega)\) such that \((A_{i22} - HC)\) generates a strongly continuous semi-group \((S_{i2}(t))_{t \geq 0}\) which is \(\Omega_{ER}\)-stable.

**Remark 4.8:** The relation (34) is true on a given subdomain \(\omega \subset \Omega\), i.e.

\[ \| x_\omega S_{i22}(t) \|_{L^2(\omega), L^2(\Omega)} \leq M_{i22} e^{-\alpha_{i22}(t)}, t \geq 0 \] (35)

and then

\[ \lim_{t \to 0} \| x_\omega(., t) \|_{L^2(\omega)} = 0 \]

We refer to this as regional exponential reduced stability (or \(\omega_{ER}\)-stability).

**Definition 4.9:** The system \((32)\) The system is said to be regional exponential reduced stability (or \(\omega_{ER}\)-stable) if the operator \(A_{i22}\) generates a semi-group which is \(\omega_{ER}\)-stable.

In this section, we shall extend the definition of \(\Omega_{ER}\)-detectable (35) to the regional case by considering \(\omega\) as subregion of \(\Omega\).

**Definition 4.10:** The system \((32)-(33)\) is said to be regional exponential reduced detectable (or \(\omega_{ER}\)-detectable) if there exists a bounded operator \(H: R^q \to L^2(\omega)\) such that \((A_{i22} - H_{\omega} A_{i22})\) generates a strongly continuous semi-group \((S_{\omega i22}(t))_{t \geq 0}\), which is \(\omega_{ER}\)-stable.

From proposition 3.1, we have the dynamical system for \((32)-(33)\) may be given by

\[
\begin{cases}
\frac{\partial \xi}{\partial t} = A_{i22} \xi(., t) + [B_{i2} u(., t) + A_{i21} y(., t)] + H_{\omega} [y(., t) - A_{i22} \xi(., t)] & \text{if } \theta \\
\xi(\eta, 0) = 0 & \text{if } \theta \\
\xi(\xi, 0) = 2_{\omega i22}(\xi) & \text{if } \Omega
\end{cases}
\] (36)

where \((A_{i22} - H_{\omega} A_{i22})\) generates a strongly continuous semi-group \((S_{\omega i22}(t))_{t \geq 0}\) which is \(\omega_{ER}\)-stable on the Hilbert space \(X = L^2(\Omega)\), \((B_{i2} - H_{\omega} B_{i2}) \in L(R^q, X_2)\) and

\[ (A_{i22} - H_{\omega} A_{i22} - H_{\omega} A_{i22} - H_{\omega} A_{i22} - A_{i21}) \in L(R^q, X_2) \] [7].

The importance of reduced \(\omega_{ER}\)-detectability is possible to define a reduced \(\omega_{ER}\)-estimator for system state may be given by the following important result:

**Theorem 4.11:** If there are \(q\) sensors \((D_{ij}, f_{ij})_{i \leq j \leq 2q}\) and the spectrum of \(A_{22}\) contains \(j\) eigenvalues with non-negative real parts. The system \((32)-(33)\) is \(\omega_{ER}\)-detectable iff

1. \(q \geq m_2\)
2. \(\text{Rank } G_{2i} = m_{2i}, \forall i, i = 1, ..., f\) with

\[ G_2 = G_{2i} = \begin{cases} (\phi_{ji}(.), f_{ij}(.) \right|_{L^2(\omega_j)}, \text{ for zone sensors} \\
(\phi_{ji}(b_i), \text{ for pointwise sensors} \\
\end{cases} \]

where \(\inf m_{2i} = m_2 < \infty\) and \(j = 1, ..., \infty\).

**Proof:** The proof is developed to the case of zone sensors in the following steps:

1. The system \((32)\) can be decomposed by the projections \(P\) and \(I - P\), on two parts, unstable and stable under the assumptions of section 4.2, where \(P\) and \((I - P)\) play the role of projection as \(E_1, E_2\) in section 4.1. The state vector may be given by

\[ x_2(\xi, t) = [x_2(\xi, t)x_2(\xi, t)]^{tr} \]
where \( x_2(t) \) is the state component of the unstable part of system (32), may be written in the form

\[
\begin{align*}
\frac{dx_2(t)}{dt} &= A_{22}x_2(t) + \mathcal{P}[A_{21}x_1(t) + B_2u(t)] Q \\
x_2(\eta, t) &= 0 \quad \theta(37) \\
x_2(t, 0) &= x_{20}(t) \quad \Omega
\end{align*}
\]

and \( x_{22}(t) \) is the component state of the stable part of system (32), given by

\[
\begin{align*}
\frac{dx_{22}(t)}{dt} &= A_{22}x_{22}(t) + (I - \mathcal{P})[A_{21}x_1(t) + B_2u(t)] Q \\
x_{22}(\eta, t) &= 0 \quad \theta(38) \\
x_{22}(t, 0) &= x_{200}(t) \quad \Omega
\end{align*}
\]

The operator \( A_{22} \) is represented by a matrix of order \((\Sigma_{i=1}^1 m_2, \Sigma_{i=1}^1 m_2)\) given by

\[ A_{22} = \text{diag}[\lambda_2, ..., \lambda_2, ..., \lambda_2, ..., \lambda_2] \]

and

\[ \mathcal{P}B_2 = \begin{bmatrix} G_{22}^U & G_{22}^V & ... & G_{22}^W \end{bmatrix} \]

From condition (2) of this theorem, then the suite of sensors \((D_j, f_j)_{1 \leq j \leq S} \) is \( \omega_R \)-strategic for the unstable part of the system (32), the subsystem (37) is weakly regionally reduced-observable in \( \omega \) (or weakly \( \omega_R \)-observable) and since it is finite dimensional, then it is exactly regionally reduced-observable in \( \omega \) (or exactly \( \omega_R \)-observable).

Therefore it is \( \omega_{ER} \)-detectable, and hence there exists an operator \( \mathcal{H}^1 \) such that \((A_{221} - \mathcal{H}^1A_{212})\) which satisfies the following:

\[ \exists M_{1w}^1, \alpha_1^w > 0 \text{ such that } \left\| e^{(A_{221} - \mathcal{H}^1A_{212})\tau} \right\|_{L^2(\omega)} \leq M_{1w}^1 e^{-\alpha_1^w \tau} \]

and we have

\[ \left\| x_2(\ell, t) \right\|_{L^2(\omega)} \leq M_{1w}^1 e^{-\alpha_1^w \tau} \left\| \mathcal{P}x_2(\ell, t) \right\|_{L^2(\omega)} \]

Since the semi-group generated by the operator \( A_{22} \) is \( \omega_{ER} \)-stable,

\[ \exists M_{2w}^2, \alpha_2^w > 0 \text{ such that } \left\| x_2(\ell, t) \right\|_{L^2(\omega)} \leq M_{2w}^2 e^{-\alpha_2^w \tau} \left\| (I - \mathcal{P})x_2(\ell, t) \right\|_{L^2(\omega)} \]

\[ + \int_0^\tau M_{2w}^2 e^{-\alpha_2^w (\tau - \tau)} \left\| (I - \mathcal{P})x_2(\ell, t) \right\|_{L^2(\omega)} \| u(t) \| dt \]

and therefore \( x_2(\ell, t) \to 0 \) when \( t \to \infty \). Thus, the system (32)-(33) is \( \omega_{ER} \)-detectable.

2) If the system (32)-(33) is \( \omega_{ER} \)-detectable, then

\[ \exists \mathcal{H} \in L(L^2(0, \infty, \mathfrak{R}^S), L^2(\omega)) \text{ such that } (A_{22} - \mathcal{H}A_{122}) \text{ generates an } \omega_{ER} \text{-stable, strongly continuous semi-group } (S_{\mathcal{H}}(t))_{t \geq 0} \text{ on the space } L^2(\omega) \text{ which satisfies the following:} \]

\[ \exists M_{\omega}, \alpha_0^\omega > 0 \text{ such that } \left\| S_{\mathcal{H}}(t) - I \right\|_{L^2(\omega)} \leq M_{\omega} e^{-\alpha_0^\omega \tau} \]

Thus the unstable subsystem (37) is \( \omega_{ER} \)-detectable. Since this subsystem is of finite dimension, then it is exactly \( \omega_R \)-observable. Therefore (37) is weakly \( \omega_R \)-Observable and hence it is reduced \( \omega_R \)-strategic, i.e.

\[ [\mathcal{K}_{\mathcal{H}}^0, x_2^*(\cdot, t) = 0 \Rightarrow x_2^*(\cdot, t) = 0] \text{. For } x_2^*(\cdot, t) \in L^2(\omega) \text{ we have} \]

\[ \mathcal{K}_{\mathcal{H}}^0 x_2^*(\cdot, t) = \sum_{j=1}^J e^{\lambda_j \tau} (\psi_j(\cdot), x_2^*(\cdot, t))_{L^2(\omega)} (\psi_j(\cdot), f_j(\cdot))_{L^2(\omega)} \]

If the unstable system (37) is not \( \omega_R \)-strategic, \( \exists x_2^*(\cdot, t) \in L^2(\omega) \) such that \( \mathcal{K}_{\mathcal{H}}^0 x_2^*(\cdot, t) = 0 \) this leads to

\[ \sum_{j=1}^J (\psi_j(\cdot), x_2^*(\cdot, t))_{L^2(\omega)} (\psi_j(\cdot), f_j(\cdot))_{L^2(\omega)} = 0 \]

the state vectors \( x_{2i} \) may be given by

\[ x_{2i}(\cdot, t) = [(\psi_1(\cdot), x_{2i}^*(\cdot, t))_{L^2(\omega)} (\psi_j(\cdot), x_{2i}^*(\cdot, t))_{L^2(\omega)}]_{i}^J \neq 0 \]
we then obtain $G_2, x_i = 0, \forall i = 1, ..., J$ and therefore $\text{Rank} \ G_2 \neq m_2$.

Here, we construct the $\omega_{ER}$-estimator for parabolic distributed parameter system (1), we need to present the following remarks.

**Remark 4.12**: Now, choose the following decomposition:

$$\dot{z} = \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} y \\ \varphi + \mathcal{H}_u y \end{bmatrix}$$

which estimates exponentially the state vector $x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$

Then, the dynamical system (36) is given by the following system:

$$\left\{ \begin{array}{l} \frac{\partial \varphi}{\partial t}(\xi, t) = (A_{22} - \mathcal{H}_u A_{12}) \varphi(\xi, t) \\
+ [A_{22} \mathcal{H}_u - \mathcal{H}_u A_{12} \mathcal{H}_u - \mathcal{H}_u A_{11} + A_{21}] y(\xi, t) + [B_2 - \mathcal{H}_u B_1] u(t) \\
\varphi(\eta, t) = 0 \\
\varphi(\xi, 0) = \varphi_0(\xi) \end{array} \right. \Omega \quad (39)$$

which defines an $\omega_{ER}$-estimator for $T_u x_2(\xi, t)$ if

1. $\lim_{t \to \infty} \| \varphi(\xi, t) - T_u x_2(\xi, t) \|_{L^2(\omega)} = 0$
2. $T_u : D(A_{22}) \to D(A_{22} - \mathcal{H}_u A_{12})$ where $T_u = \mathcal{X}_u T$ and $\varphi(\xi, t)$ is the solution of system (39).

**Remark 4.13**: The dynamical system (39) observes the regional reduced state of the system (1) if the following conditions satisfy:

1. $\exists \xi \in L(0, L^2(\omega))$ and $M \in L(L^2(\omega))$ such that:

$$L A_{12} + MT_u = I_\omega$$
2. $T_u A_{22} - (A_{22} - \mathcal{H}_u A_{12}) T_u = \mathcal{H}_u A_{12}$ and $(B_2 - \mathcal{H}_u B_1) = T_u B_2$
3. The system (39) defines an $\omega_{ER}$-estimator for the system (1).
4. If $X = x_2$ and $T_u = I_\omega$, then in the above case, we have

$$A_{22} - (A_{22} - \mathcal{H}_u A_{12}) = \mathcal{H}_u A_{12}$$

**Remark 4.14**: The system (1) is $\omega_{ER}$-observable if there exists an $\omega_{ER}$-estimators (39) which estimate the regional exponential reduced state of this system.

Now, we present the sufficient condition of the regional exponential reduced observability notion as in the following main result.

**Theorem 4.15**: If the system (32)-(33), is $\omega_{ER}$-detectable, then it is $\omega_{ER}$-observable by the dynamical system (39), that means

$$\lim_{t \to \infty} \left\| \left( \varphi(\xi, t) + \mathcal{H}_u y(\xi, t) \right) - x_2(\xi, t) \right\|_{L^2(\omega)} = 0,$$

**Proof**: The solution of the dynamical system (36) is given by

$$\dot{z}(\xi, t) = S_{\mathcal{H}_u}(t) \dot{x}_0(\xi) + \int_0^t S_{\mathcal{H}_u}(t - \tau) [B_2 u(\tau)] d\tau + A_{21} y(\xi, t) + \mathcal{H}_u \tilde{y}(\xi, t) \right) dt \quad (40)$$

From the equations (32) and (33), we have

$$\tilde{y}(\xi, t) = A_{12} x_1(\xi, t) = \frac{\partial x_1}{\partial t}(\xi, t) - A_{11} x_1(\xi, t) - B_1 u(t) \quad (41)$$

By using (41) and (40), we obtain

$$\dot{z}(\xi, t) = S_{\mathcal{H}_u}(t) \dot{x}_0(\xi) + \int_0^t S_{\mathcal{H}_u}(t - \tau) \mathcal{H}_u \frac{\partial x_1}{\partial t}(\xi, t) d\tau + \int_0^t S_{\mathcal{H}_u}(t - \tau) [B_2 u(\tau) + A_{21}] y(\xi, t)$$
and we can get
\[ \int_0^t S_{\mathcal{H}_w}(t - \tau) \mathcal{H}_w \frac{\partial x_1}{\partial t}(\xi, \tau) d\tau = \mathcal{H}_w x_1(\xi, t) - S_{\mathcal{H}_w}(t) \mathcal{H}_w x_0(\xi) \]
\[ + \left( A_{22} - \mathcal{H}_w A_{12} \right) \int_0^t S_{\mathcal{H}_w}(t - \tau) \mathcal{H}_w x_1(\xi, \tau) d\tau \]  \hspace{1cm} (43)

Using Bochner integrability properties and closeness of \((A_{22} - \mathcal{H}_w A_{12})\), the equation (43) becomes
\[ \int_0^t S_{\mathcal{H}_w}(t - \tau) \mathcal{H}_w \frac{\partial x_1}{\partial t}(\xi, \tau) d\tau = \mathcal{H}_w x_1(\xi, t) - S_{\mathcal{H}_w}(t) \mathcal{H}_w x_0(\xi) \]
\[ + \left( \int_0^t S_{\mathcal{H}_w}(t - \tau) \right) \left( A_{22} - \mathcal{H}_w A_{12} \right) \mathcal{H}_w x_1(\xi, \tau) d\tau \]  \hspace{1cm} (44)

Substituting (44) into (42), we have
\[ \dot{z}(\xi, t) = S_{\mathcal{H}_w}(t) \dot{z}_0(\xi) - S_{\mathcal{H}_w}(t) \mathcal{H}_w x_0(\xi) + \mathcal{H}_w x_1(\xi, t) \]
\[ + \int_0^t S_{\mathcal{H}_w}(t - \tau) \left( A_{22} - \mathcal{H}_w A_{12} \right) \mathcal{H}_w x_1(\xi, \tau) d\tau \]  \hspace{1cm} (45)

Setting \( \varphi(\xi, t) = \dot{z}(\xi, t) - \mathcal{H}_w y(\xi, t) \), with \( \dot{\varphi}(\xi, 0) = \dot{z}_0(\xi) - \mathcal{H}_w x_0(\xi) \), whereby \( y(\xi, 0) = x_0(\xi) \). Now, assume that \((A_{22} - \mathcal{H}_w A_{12})\) and \((B_2 - \mathcal{H}_w B_1)\) are bounded operators, the equation (45) can be differentiated to yield the following system
\[ \begin{cases} 
\frac{\partial \varphi}{\partial t}(\xi, t) = (A_{22} - \mathcal{H}_w A_{12}) \varphi(\xi, t) + (A_{22} - \mathcal{H}_w A_{12}) \mathcal{H}_w \varphi(\xi, t) - \mathcal{H}_w A_{11} A_{21} y(\xi, t) + (B_2 - \mathcal{H}_w B_1) u(t) \Omega \\
\varphi(\eta, t) = 0 \\
\varphi(\xi, 0) = \varphi_0(\xi) \end{cases} \]
and therefore
\[ \frac{\partial x_2}{\partial t}(\xi, t) = \frac{\partial x_2}{\partial t}(\xi, t) = (\varphi(\xi, t) + \mathcal{H}_w y(\xi, t) - x_2(\xi, t)) \]
\[ = (A_{22} \dot{z}(\xi, t) + B_2 u(t) + A_{21} y(\xi, t) + \mathcal{H}_w y(\xi, t) - A_{21} x_1(\xi, t) - A_{22} x_2(\xi, t) - B_2 u(t) \]
\[ = (A_{22} - \mathcal{H}_w A_{12}) (\dot{z}(\xi, t) - x_2(\xi, t)) \]  \hspace{1cm} (46)

From the relation
\[ \left\| x_2 \left( \mathcal{H}_w S_{\mathcal{H}_w}(t) x_2(\xi) \right) \right\|_{\mathcal{L}^2(\omega)} \leq M_{\mathcal{L}} e^{-\alpha \mathcal{H}_w t} \left\| x_2(\xi) \right\|_{\mathcal{L}^2(\omega)} \]
we obtain
\[ \left\| \dot{z}(\xi, t) - x_2(\xi, t) \right\|_{\mathcal{L}^2(\omega)} \leq \left\| x_2 \left( \mathcal{H}_w S_{\mathcal{H}_w}(t) \right) \right\|_{\mathcal{L}^2(\omega)} \left\| \dot{z}(\xi, 0) - x_2(\xi, 0) \right\|_{\mathcal{L}^2(\omega)} \]
\[ \leq M_{\mathcal{L}} e^{-\alpha \mathcal{H}_w t} \left\| \dot{z}(\xi, 0) - x_2(\xi, 0) \right\|_{\mathcal{L}^2(\omega)} \]  \hspace{1cm} (47)

where the component \( \dot{z}(\xi, t) \) is an exponentially estimator of \( x_2 \); then, we have the system (36) is a \( \omega_{EX}\) observable for the system (32)-(33).

From the previous theorem 4.15, we can deduce the following definition which characterizes another new strategic sensor:

Definition 4.16: A sensors is \( \omega_{EX}\) strategic sensor if the corresponding system is \( \omega_{EX}\) observable.

5. APPLICATIONS TO EXCHANGE SYSTEMS

Consider the case of two-phase exchange system described by the following coupled parabolic equations:
\[ \begin{cases} 
\frac{\partial x_1}{\partial \tau}(\xi_1, \xi_2, t) = \alpha \frac{\partial^2 x_1}{\partial \xi_2^2}(\xi_1, \xi_2, t) + \beta (x_1(\xi_1, \xi_2, t) - x_2(\xi_1, \xi_2, t)) Q \\
\frac{\partial x_2}{\partial \tau}(\xi_1, \xi_2, t) = \gamma \frac{\partial^2 x_2}{\partial \xi_2^2}(\xi_1, \xi_2, t) + \beta (x_2(\xi_1, \xi_2, t) - x_1(\xi_1, \xi_2, t)) Q \\
x_1(\eta_1, \eta_2, 0) = x_{01}(\eta_1, \eta_2) \quad x_2(\eta_1, \eta_2, 0) = x_{02}(\eta_1, \eta_2) \end{cases} \]  \hspace{1cm} (48)

and consider \( \Omega = (0,1) \times (0,1) \) with subregion \( \omega = (\alpha_1, \beta_1) \times (\alpha_2, \beta_2) \subset \Omega \). Suppose that it is possible to measure the states \( x_1(\xi, t) \), by using \( q \) zone sensors \( (D_q)_{E \in \Omega} \). The output function (2) is given by
\[
y(t) = Cx_1(., t) = \left[ \int_{\Omega} x_1(\xi, t) f_1(\xi) d\xi \ldots \int_{\Omega} x_1(\xi, t) f_q(\xi) d\xi \right]^T.
\]

Now, the problem is to estimate exponentially \( x_2(\xi, t) \).

Let us consider

\[
\frac{\partial x}{\partial t} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \tag{49}
\]

where

\[
A_{11} = \alpha \frac{\partial^2 x_1}{\partial \xi^2}(\xi_1, \xi_2, t) + \beta, A_{22} = \gamma \frac{\partial^2 x_2}{\partial \xi^2}(\xi_1, \xi_2, t) + \beta
\]

and \( A_{12} = A_{21} = -\beta I \).

From theorem 4.11, we can construct regional reduced estimator for system (48) if the sensors \((D_i, f_i)_{1 \leq i \leq q}\) are \(\omega\)-strategic for the unstable part of the subsystem

\[
\begin{aligned}
\frac{\partial x_1}{\partial t}(\xi_1, \xi_2, t) &= \gamma \frac{\partial^2 x_1}{\partial \xi^2}(\xi_1, \xi_2, t) + \beta(x_1(\xi_1, \xi_2, t) \\
-x_2(\xi_1, \xi_2, t)) = 0 \\
x_1(\eta_1, \eta_2, t) &= 0 \\
x_2(\eta_1, \eta_2, t) &= 0 \tag{50}
\end{aligned}
\]

where \( \gamma = 0.1 \) and \( \beta = 1 \). If we choose the sensors \((D_i, f_i)_{1 \leq i \leq q}\) such that

\[
y(t) = \left[ \int_{\Omega} x_1(\xi_1, \xi_2, t) f_1(\xi_1, \xi_2) d\xi_1 d\xi_2 \ldots \int_{\Omega} x_1(\xi_1, \xi_2, t) f_q(\xi_1, \xi_2) d\xi_1 d\xi_2 \right]^T \neq 0,
\]

then, there exists \( \mathcal{H}_w \in L(R^q, L^2(\omega)) \) such that the operator \((A_{22} - \mathcal{H}_w A_{12})\) generates a strongly continuous stable semigroup on the space \( L^2(\omega) \). Thus we have

\[
\lim_{n \to \infty} \| (w(., t) + \mathcal{H}_w x_1(., t)) - x_2(., t) \|_{L^2(\omega)} = 0,
\]

where

\[
\begin{aligned}
\frac{\partial w}{\partial t}(\xi_1, \xi_2, t) &= \gamma \frac{\partial^2 w}{\partial \xi^2}(\xi_1, \xi_2, t) + \beta(1 + \mathcal{H}_w) w(\xi_1, \xi_2, t) \\
&(\gamma - \alpha) \frac{\partial w}{\partial \xi}(\xi_1, \xi_2, t) + (\mathcal{H}_w^2 - 1)(\xi_1, \xi_2, t)) \tag{51}
\end{aligned}
\]

\[
\begin{aligned}
w(\xi_1, \xi_2, 0) &= w_0(\xi_1, \xi_2) \\
w(\eta_1, \eta_2, t) &= 0 \tag{52}
\end{aligned}
\]

In this section, we give the specific results related to some examples of sensors locations and we apply these results to different situations of the domain, which usually follow from symmetry considerations.

We consider the two-dimensional system defined on \( \Omega = (0, 1) \times (0, 1) \) with the case of system described by the following equations:

\[
\begin{aligned}
\frac{\partial x_1}{\partial t}(\xi_1, \xi_2, t) &= \gamma \frac{\partial^2 x_1}{\partial \xi^2}(\xi_1, \xi_2, t) + \beta x_1(\xi_1, \xi_2, t) \\
-x_2(\xi_1, \xi_2, t) &= 0 \\
x_2(\eta_1, \eta_2, t) &= 0 \tag{52}
\end{aligned}
\]

augmented with the output function
\[ y(t) = Cx_1(\cdot, t) \]  

(53)

Let \( \omega = (\alpha_1, \beta_1) \times (\alpha_2, \beta_2) \). In this case the eigenfunctions and eigenvalues for the dynamic system (52) for Neumann conditions are given by

\[
\varphi_{ij}(\xi_1, \xi_2) = \frac{2}{\sqrt{(\beta_1 - \alpha_1)(\beta_2 - \alpha_2)}} \sin \pi \left( \frac{\xi_1 - \alpha_1}{\beta_1 - \alpha_1} \right) \sin \pi \left( \frac{\xi_2 - \alpha_2}{\beta_2 - \alpha_2} \right) \quad \text{for } i \neq j
\]

\[
\lambda_{ij} = \left( \frac{i^2}{(\beta_1 - \alpha_1)^2} + \frac{j^2}{(\beta_2 - \alpha_2)^2} \right) \pi^2, \quad i, j \geq 1 \quad \text{(54)}
\]

We examine the two cases illustrated in Fig. (2)-(3).

### 5.1 Internal Rectangular Sensor

For discussing this case, suppose the system (52)-(53) where the sensor supports \( D \) is the located in \( \Omega \). The output function can be written by the form

\[
y(t) = \int_D x_2(\xi_1, \xi_2, t)f_1(\xi_1, \xi_2)d\xi_1d\xi_2,
\]

(56)

where \( D \subset \Omega \) is the location of zone sensor as in (Figure 3).

Fig. 3: Rectangular domain, region \( \omega \) and location \( D \) with rectangular support sensor

Then, the sensor \( (D_i, f_i)_{i \in \mathbb{N}} \) may be sufficient for \( \omega_{ER} \)-observability, and there exists \( \mathcal{H}_\omega \subset L^2(\mathbb{R}^n) \) such that the operator \( \left( A_{22} - \mathcal{H}_\omega A_{11} \right) \) generates a strongly continuous stable semi-group on the space \( L^2(\omega) \). Thus we have

\[
\lim_{t \to \infty} \| e^{\mathcal{H}_\omega t}w(\xi_1, \xi_2, t) + \mathcal{H}_\omega x_2(\xi_1, \xi_2, t) - x_1(\xi_1, \xi_2, t) \|_{L^2(\omega)} = 0,
\]

where

\[
\begin{cases}
\frac{\partial w}{\partial t}(\xi_1, \xi_2, t) = \frac{\partial^2 w}{\partial \xi_1^2}(\xi_1, \xi_2, t) + \beta((1 + \mathcal{H}_\omega)w(\xi_1, \xi_2, t)) + (y - a\mathcal{H}_\omega)\frac{\partial w}{\partial \xi_2}(\xi_1, \xi_2, t) + (\mathcal{H}_2^2 - 1)(\xi_1, \xi_2, t)) Q & \Omega \\
\frac{w(\xi_1, \xi_2, 0)}{\xi_1, \xi_2, t} = w_0(\xi_1, \xi_2) & \partial \\
\frac{w(\xi_1, \xi_2, t)}{\xi_1, \xi_2, t} = 0 & \partial
\end{cases}
\]

(57)

Then, we have the following result

**Proposition 5.1:** Suppose \( \omega = D_1 = \pi^2 \sum_{i=1}^{n}[\xi_i - \xi_i, \beta_i - \xi_i] \subset \Omega \) as in (Figure 3). Then the sensor \( (D_i, f_i)_{i \in \mathbb{N}} \) is not \( \omega_{ER} \)-observable by the \( \omega_{ER} \)-estimator (57), if for any \( i_0 \in \{1, 2\}, i_0(\xi_{i_0} - \alpha_{i_0})/(\xi_{i_0} - \beta_{i_0}) \in Q \) and \( f_i \) is symmetric about the line \( \xi_{i_0} = \xi_{i_0} \).

**Proof:** Suppose \( i_0 = 1 \), \( (\xi_{i_0} - \alpha_{i_0})/(\xi_{i_0} - \beta_{i_0}) \in Q \), then there exists \( j_0 \geq 1 \) such that \( \sin(j_0\pi c_1/\beta_{i_0}) = 0 \). But

\[
y(t) = \langle f_1, \varphi_{i_0, 0} \rangle = \left( \frac{4}{(\beta_1 - \alpha_1)(\beta_2 - \alpha_2)} \right)^{1/2} \int_{\alpha_2 - \xi_2}^{\alpha_1 + \xi_1} \int_{a_2 - \xi_2}^{a_1 - \xi_2} f_1(\xi_1, \xi_2) \sin(j_0\pi \xi_1) \left( \frac{\xi_1}{\beta_1 - \alpha_1} \right) \sin(j_0\pi \xi_2) \left( \frac{\xi_2}{\beta_2 - \alpha_2} \right) d\xi_1 d\xi_2
\]

If \( f_1 \) is symmetric about \( \xi_1 = x_2 \) the integral in the square bracket is zero and hence \( y(t) = \langle f_1, \varphi_{i_0, 0} \rangle = 0 \).

### 5.2 Internal circular sensor
Consider the system (52) augmented with the output function $y(t) = Cx_1(\cdot, t)$ where the sensor supports $D_i$ is located inside the domain $\Omega$. The output $y(t) = Cx_1(\cdot, t)$ can be written by the following form

$$y(t) = \int_{\Theta} x_1(r, \theta, t) f_i(r, \theta) d\theta,$$

where $D_i = (r, \theta) \subset \Omega$, is the location of zone sensor as in (Figure 4).

Fig 4: Rectangular domain, region $\omega$ and location $D$ with circular support sensor

Then, the sensor $(D_i, f_i)_{1 \leq i \leq 2}$ may be sufficient for $\omega_{EX}$-observability, and there exists $\mathcal{H} \in \mathcal{L}(R^q, L^2(\omega))$ such that the operator $(A_{2\mathbb{Z}} - \mathcal{H}_w A_{1\mathbb{Z}})$ generates a strongly continuous stable semi-group on the space $L^2(\omega)$. Thus we have

$$\lim_{t \to 0+} ||(w(r, \theta, t) + \mathcal{H}_w x_2(r, \theta, t)) - x_1(r, \theta, t)||_{L^2(\omega)} = 0,$$

where

$$\left\{ \begin{array}{l}
\frac{\partial w}{\partial t} (r, \theta, t) = \frac{\partial^2 w}{\partial r^2} (r, \theta, t) + \beta ((1 + \mathcal{H}_w) w(r, \theta, t) \\
+ (y - \alpha \mathcal{H}_w) \frac{\partial}{\partial r} (r, \theta, t) + (\mathcal{H}_w^2 - 1)(r, \theta, t)) \end{array} \right\} \Omega (59)$$

Then, we have the following result:

**Proposition 5.2:** Suppose $\omega = D = D_4(c, r) \subset \Omega = \pi \mathbb{Z} - (0, 1)c = (c_1, c_2)$. Then the sensor $(D_i, f_i)_{1 \leq i \leq 2}$ is not $\omega_{EX}$-observable by the $\omega_{EX}$-estimator (59), if for any $i_0 \in (1, 2), i_0 ((c_{i_0} - \alpha_i)/(c_{i_0} - \beta_i) \in \mathbb{Q}$ and $f_i$ is symmetric about the line $x_{i_0} = c_{i_0}$.

**Proof:** suppose $i_0 = 1$, then there exists $j_0 \geq 1$ such that $\cos(j_0 \pi c_1/\beta_1 + \alpha_1) = 0$. Consider the output function (53) with the change of variable $x_2 = c_1 + \tilde{r} \cos \theta, x_2 = c_2 + \tilde{r} \sin \theta$, then

$$y(t) = \langle f_1, \varphi, \psi \rangle = 4 \left( \frac{\tilde{r}_1 - \alpha_1}{\tilde{r}_1 - \alpha_2} \right)^{1/2} \int_0^{2\pi} \int_0^r \tilde{r}_1 f_1(c_1 + \tilde{r} \cos \theta, c_2 + \tilde{r} \sin \theta) \sum_{j_0} \left( \frac{\pi(c_1 + \tilde{r} \cos \theta)}{\tilde{r}_1 - \alpha_1} \right)^{1/2} \tilde{r}_1 d\tilde{r}_1 d\theta,$$

Since $f_1$ is symmetric about $x_2 = c_1$, the function

$$(\tilde{r}, \theta) \rightarrow f_1(c_1 + \tilde{r} \cos \theta, c_2 + \tilde{r} \sin \theta) \cos \left( \frac{\pi(c_1 + \tilde{r} \cos \theta)}{(\tilde{r}_1 - \alpha_2)^{1/2}} \right)$$

is symmetric on $[0, \pi]$ about $\theta = \pi/2$ for all $\tilde{r}$. But the function

$$(\tilde{r}, \theta) \rightarrow \sin \left( \frac{\pi(c_1 + \tilde{r} \cos \theta)}{(\tilde{r}_1 - \alpha_1)} \right)$$

is antisymmetric on $[0, \pi]$ about $\pi/2$. By decomposing the integral as a sum on $[0, \pi)$ and $[\pi, 2\pi)$ it is easy to see that

$$y(t) = \langle f_1, \varphi, \psi \rangle = 0.$$

**Remark 5.3:** These results can be extended to the following:

1. Case of Neumann or mixed boundary conditions.
2. Case of boundary (pointwise, zone) sensors.

**6. CONCLUSION**

The concept developed in this paper is related to the regional exponential reduced observability in connection with the strategic sensors. Various interesting results concerning the choice of circular sensors are given and illustrated in specific situations. Many questions still open. This is the case of, for example, the problem of finding the optimal sensor location...
ensuring such an objective. The result of regional exponential reduced observability concept of hyperbolic linear or semi linear or nonlinear systems is under consideration.

ACKNOWLEDGMENTS

Our thanks in advance to the editors and experts for considering this paper to publish in this estimated journal and for their efforts.
