Transplant vasculopathy (TV), characterized by obstructive lesions in affected vessels, represents one of the long-term complications of cardiac transplantation. Activation of the transcription factor activator protein-1 (AP-1) is implicated in smooth muscle cell (SMC) phenotypic switch from contractile to synthetic function, increasing the migration and proliferation rate of these cells. We hypothesize that adeno-associated virus (AAV)-mediated delivery of an RNA hairpin AP-1 decoy oligonucleotide (dON) might effectively ameliorate TV severity in a mouse aortic allograft model. Aortic allografts from DBA/2 mice ex vivo transduced with modified AAV9-SLR carrying a targeting peptide within the capsid surface were transplanted into the infrarenal aorta of C57BL/6 mice. Cyclosporine A (10 mg/kg BW) was administered daily. AP-1 dONs were intracellularly expressed in the graft tissue as small hairpin RNA proved by fluorescent in situ hybridization. Exploitation after 30 days and histomorphometric evaluation revealed that AP-1 dON treatment significantly reduced intima-to-media ratio by 41.5% (p < 0.05) in the grafts. In addition, expression of adhesion molecules, cytokines, as well as numbers of proliferative SMCs, matrix metalloproteinase-9-positive cells, and inflammatory cell infiltration were significantly decreased in treated aortic grafts. Our findings demonstrate the feasibility, efficacy, and specificity of the anti-AP-1 RNA dON approach for the treatment of allograft vasculopathy in an animal model. Moreover, the AAV-based approach in general provides the possibility to achieve a prolonged delivery of nucleic-acid-based therapeutics in to the blood vessel wall.

INTRODUCTION

Transplant vasculopathy (TV) remains one of the main complications hindering long-term graft survival, thus representing a major risk factor for mortality in patients subjected to solid organ transplantation. Although acute cellular rejection can be controlled with immunosuppressive drugs such as cyclosporine A (CsA) or tacrolimus, grafts with significant intimal thickening and accelerated progression of cardiac allograft vasculopathy CAV have the poorest survival prognosis.

AAV-Mediated Expression of AP-1-Neutralizing RNA Decoy Oligonucleotides Attenuates Transplant Vasculopathy in Mouse Aortic Allografts

without immunosuppressive therapy, we used CsA in our study. Short-term ex vivo incubation with the AAV vector solution allows transduction and continuous long-term expression of the active nucleic acid drug as small hairpin RNA (shRNA) in vascular target cells and exerts a profound therapeutic effect by alleviating lumen stenosis.

RESULTS

hpAP-1 dODN Specificity and Binding Affinity

The apparent affinity with which the hairpin AP-1 (hpAP-1) dODN specifically binds to the target transcription factor was determined by an ELISA approach. In this assay, a nuclear extract from stimulated cells containing the activated AP-1 transcription factor is allowed to bind to an immobilized double-stranded DNA (dsDNA) probe comprising its consensus sequence. The binding and the displacement of AP-1 from this probe by the hpAP-1 dODN was visualized by using a specific antibody against the active form of AP-1 (Figure 1). The average apparent affinity expressed as half maximal inhibitory concentration (IC$_{50}$) was determined at 2.5 nM for the consensus hpODN. The corresponding mutated control hpODN does not seem to bind to the transcription factor in the tested range of concentrations.

Tissue-Specific hpAP-1 Decay ON Expression after AAV Serotype 9 (AAV9)SLR Transduction

Next, we confirmed the expression and presence of hpAP-1 RNA dONs in aortic tissue transduced with the designed vector (Figure 1B) 30 days after transplantation. For this purpose, 7-µm-thick aortic frozen sections were subjected to fluorescence in situ hybridization (FISH) analysis (n = 9 animals, 2 sections/mouse). As shown in Figures 1C and 1D, 80% ± 2% of neo-intimal cells expressed hpAP-1 decay ODNs, proving successful transduction and generation of the active nucleic acid drug 30 days after ex vivo transduction and reimplantation into recipient mice. No fluorescent signal was detected in non-transduced tissue or in samples using a non-related control molecular beacon, demonstrating the specificity of the detection method.

AAVSLR-Mediated hpAP-1 dON Delivery Attenuates Neointima Formation

Morphometric analysis revealed that control non-treated mice developed vascular lesions and intense remodeling, accompanied by high degrees of vessel lumen obstruction. In these grafts, an increased expression of the AP-1 family member c-Jun and also c-Jun N-terminal kinase (JNK) could be demonstrated (Figure S1). Similarly, treatment with AAV9SLR expressing the mutated control hpAP-1 dONs had no effect on this parameter, whereas the consensus hpAP-1 dON delivery led to a significant decrease in neointima formation, proven by a neointima/media ratio reduction of 41.5% compared to controls (Figure 2).

AAVSLR-Mediated hpAP-1 dON Delivery Decreases SMC Proliferation

SMC proliferation has been shown to be an initial event in response to vascular injury, contributing to neointima formation in various animal models of TV. Elucidating the molecular mechanisms of the observed therapeutic effects, we analyzed cyclin D2 expression as a regulatory protein of the cell cycle in the transplanted aortic tissue. Compared to control groups, grafts transduced with AAV9SLR expressing hpAP-1 consensus dONs exhibited a significant 2.6-fold decline (p < 0.05) and 3-fold (p < 0.01) decline in cyclin D2-positive SMC population in the neointima compared to control and mutated AAV, respectively (Figure 3).

AAVSLR-Mediated hpAP-1 dON Delivery Mitigates Immune Cell Infiltration

Immune cell infiltration into the aortic tissue is a well-characterized process that contributes to graft rejection. Recruitment of inflammatory cells involves the expression of adhesion molecules such as, e.g., VCAM-1. As previously reported, we detected
VCAM-1 expression not only in endothelial cells but also in neointimal SMCs in control groups, while it was significantly decreased by 70% and 64.9% (p < 0.05) in aortic tissue receiving gene therapy, as compared to control and AAV hpAP-1 mut-treated grafts, respectively (Figure 4). Furthermore, we analyzed the degree of macrophage and CD4⁺ T cell accumulation in aortic grafts of the different treatment groups. As expected, we detected highly abundant inflammatory cell infiltrates in control tissue in both neointima and media (Figure 5). Inhibition of AP-1 target genes like leukocyte adhesion molecule VCAM-1 led to a significant 3-fold (p < 0.05) reduction in CD4⁺ T-lymphocyte infiltration related to control and 2.6-fold (p < 0.01) compared to mutated AAV (Figures 5A and 5B). Moreover, we found a 50% decrease in monocyte/macrophage accumulation as compared to control nontreated grafts and 52% related to AAV hpAP-1 mut-transduced tissue (p < 0.05) (Figures 5C and 5D).

AAV9SLR-Mediated hpAP-1 dON Delivery Attenuates Pro-inflammatory Cytokine Expression in Transduced Aortic Allografts

The observed reduction of monocyte infiltration in the aortic tissue has led to the assumption that pro-inflammatory and chemotactic cytokines are decreased following AP-1 neutralization in transduced aortic grafts. Indeed, interleukin-6 (IL-6), interferon-γ (IFN-γ), and monocyte chemotactic protein-1 (MCP-1) mRNA expression was significantly reduced in AAV9SLR hpAP-1 cons-treated grafts, whereas the control treatment had no effect (Figures 6A–6C). Analyses of frozen graft sections confirmed a significant decrease in IL-6 (43% compared to control, 40% related to AAV hpAP-1 mut) and MCP-1 (59% compared to control and 54 related to AAV hpAP-1 mut) expression on the protein level (Figures 6D–6G).

**DISCUSSION**

Heart transplantation remains the treatment of choice for patients suffering from end-stage heart failure. The high risk of TV development is a determinant factor of graft and patient survival. Long-term administration of immunosuppressive drugs for the management of autoimmune inflammatory conditions has been proven to be successful in decreasing the rate of chronic organ rejection. However, this treatment is associated with notable side effects like elevated risk for infection, malignancy, cardiovascular disease, and bone marrow suppression. In our study, the main rationale of the CsA immunosuppressive strategy was the necessity for the feasibility of
the animal model of heterotopic transplantation model. Without immunosuppression, interposition of an aortic graft from DBA/2 mouse strain into the C57BL/6J recipient strain leads to acute cell-mediated rejection, which completely eliminates all donor-derived vascular cells from the graft within 2–3 weeks, creating a highly artificial situation of limited relevance as a model for the changes in graft vessels that occur in the clinic.28 AAV is a versatile viral vector technology that can be engineered for very specific functionality in gene therapy. It has the potential to overcome the side effects of immunosuppressive drugs by offering the possibility of ex vivo transduction of the transplant prior to implantation. AAV vectors are powerful tools for gene transfer directed into the vasculature, not only due to their low immunogenicity compared adenovirus and sustained expression of the delivered gene,29 but also for their capacity to transduce both proliferating and non-proliferating cells.30 To the best of our knowledge, this is the first report describing an AAV9-based therapy approach with the targeting peptide SLRSPP in a mouse model for TV. SLRSPP has been shown to increase the transduction efficiency in human coronary artery endothelial and smooth muscle cells.31 Based on a recent study, we designed a hairpin decoy ODN utilizing the mechanism of shRNA expression.32 Instead of working as a tool for RNAi, the shRNA bearing binding site herein neutralized efficiently AP-1 transcription factors. We can exclude the degradation of mRNA as an unspecific side effect, as the loop structure of our shRNA AP-1 decoy ODN sequence does not include the dsRNA sequence targeting RNAsse III enzymes like, e.g., Drosha and Dicer, important for RNAi-dependent sequence-specific gene silencing.33

AP-1 transcription factor is one of the regulators of both MMPs and pro-inflammatory cytokine production and a highly promising target for inhibiting TV development. Indeed, we could demonstrate an up-regulation of endogenous AP-1 levels after transplantation, which highlights the importance of AP-1 blockage with dON. Previous studies already showed that application of dODNs modulating AP-1 transcriptional activity attenuates neointima formation by decreasing the proliferative SMC capacities and inhibits inflammatory signaling pathways.15,34 Moreover, we have recently shown that AP-1 dODN application to tissue grafts prior to aortic transplantation can significantly reduce the development of TV in the same animal model by reducing SMC migration and decreasing the infiltration of inflammatory monocytes into the neointima.35 Although local application of decoy ODNs has been proven effective, our approach provides the possibility to achieve a long-term formation of AP-1 decoy ODNs in aortic smooth muscle cells after a single short-time incubation period.

In accordance with previous studies,34,36 we observed that AP-1 dODNs inhibited proliferation of neointimal SMCs and neointimal formation, as shown by cyclin D2-staining results.37 In addition, AP-1 decoy ODN has been described to significantly decrease SMC migration and arterial tissue remodeling.38

It has been reported that TV is a highly dynamic process, involving not only activated SMCs, but also cells resident in the adventitia and infiltrating inflammatory cells.39 The contribution of macrophages and activated T cells is a critical factor leading to TV formation.40 AP-1 activation creates a pro-inflammatory milieu by regulating cytokines such as MCP-1, involved in monocyte recruitment and

Figure 3. Decreased Cell Proliferation following AAV9SLR-Mediated Delivery of hpAP-1 cons dONs
(A) Representative images showing immunohistochemical staining against cyclin D2 (red) as a marker of proliferating cells. DAPI (blue) was used to mark cell nuclei, and elastin autofluorescence was recorded on the green channel. (B) Box-and-whisker plot of the level of proliferating cells, measured as percentage area of cyclin D2-positive cells in the neointima. Horizontal bars in the boxes indicate median values, boxes indicate interquartile range, and whiskers indicate range of non-outlier values (*p < 0.05, **p < 0.01; n = 14 for control, n = 7 for AAV hpAP-1 mut, n = 9 for AAV hpAP-1 cons).
differentiation. In turn, activated macrophages secrete pro-inflammatory cytokines such as IL-1, IL-12, tumor necrosis factor alpha (TNF-α), and IFN-γ, which further enhance SMC proliferation, migration, and lesion formation. Importantly, the AP-1 transcription factor family was shown to promote the expression of the leukocyte adhesion molecule VCAM-1, essential for recruitment of monocytes and T cells and migration into arterial tissue. Moreover, AP-1 blockade by adenovirus-mediated overexpression of a dominant-negative form of c-Jun in endothelial cells led to inhibition of ICAM-1 induction and functionally, to a decreased monocyte migration and infiltration. In line with these findings, we could detect a remarkable decrease in VCAM-1 protein level in grafts expressing the AP-1 cons dON, which correlated with a marked reduction in macrophage and T cell numbers present in the aortic wall, as well as decreased pro-inflammatory markers IL-6 and MCP-1.

MMP2 and MMP9 are crucial for the metabolism of the major basement membrane constituent collagen type IV. Like described before, we found these two gelatinases differentially regulated in regard to graft remodeling. MMP2 protein abundance was higher than MMP9 in the graft tissue and mainly located throughout the myointima and media, as previously described for vein graft remodeling. The hpAP-1 dON approach failed to inhibit MMP2 but not MMP9 expression, which strengthened the assumption that the two gelatinases are differentially regulated on the transcriptional level. Indeed, in rodents, the promoter region of MMP9 contains a conserved proximal AP-1 binding site, whereas that of the MMP2 has a non-canonical AP-1 binding site, different from the consensus binding site present in our hpAP-1 dON. Non-canonical sequences can be recognized by various AP-1 complexes to control gene expression.

Therefore, it seems that AP-1 plays a critical role in MMP9 expression but simply acts as one of several other regulatory transcription factors, explaining the lack of effectiveness of our dON approach in case of MMP2.

Interestingly, we identified small subset of MMP9-positive cells in the neointima of control grafts that could be positively stained for ICAM-1 but were negative for markers like F4/80 (macrophages), Sca-1 (progenitor cells), or α-SMA (activated fibrogenic cells/myofibroblasts). MMP9 is known for long time to play a key role in smooth muscle cell migration during neointima formation. ICAM-1 on smooth muscle cells in the neointima may contribute to the inflammatory reaction in the vascular wall by playing a role for leukocyte accumulation and activation of mononuclear cells, which might lead to prolongation of the inflammatory response within diseased blood vessels. However, most of the other MMP9 immunopositive cells were of different origin, which will be examined in a separate study.

Despite the effectiveness of the single graft pre-treatment with AAV9SLR vector expressing hpAP-1 dON as shRNA in mice, our study has some limitations in regard to the human application. Longer experimental follow-up periods than 30 days were not tested so far. AAVs are not immunogenic in mice, but its immunogenicity becomes apparent in large-animal models and human subjects. Humans are natural hosts of AAVs and exhibit a high seroprevalence against AAV vectors, which limits the widespread application of AAV vectors into patients with pre-existing neutralizing antibodies or memory T cells. Strategies to circumvent humoral immunity to adeno-associated viral vectors are currently in the development phase. However, for clinical application, the AAV solution can be added to...
the priming or maintenance solution of the TransMedics organ care System (OCS) heart perfusion systems. This device allows preservation of the donor heart by perfusing the organ at 34°C in a beating state, potentially reducing the detrimental effect of cold storage,\textsuperscript{55} and can be used to transport donor hearts in this state.\textsuperscript{56} In conclusion, our study offers a therapeutic approach centered on AAV-mediated long-term delivery of RNA hairpin dONs neutralizing AP-1 transcriptional activity, which effectively reduced vascular lesion severity.

MATERIALS AND METHODS

Hairpin dODN Technology, Molecular Cloning, and AAV Production

The sequences of the dODNs (Biomers, Ulm, Germany) used in our study were 5’-CTGCGGTGTGCTAGCTCACGACGAAAACGCTACG TGAGCACCAGCAG-3’ (hairpin AP-1 consensus decoy ODN, binding site shown in italics) and 5’-CTGCGGTGTGCTAAGTACGAC GAAACGCTAAGTACGACCCGAG-3’ (non-functional hairpin AP-1 control dODN, mutated base pairs are underlined).

The hairpin AP-1 dODN was designed as a single-stranded homoduplex molecule consisting of a small loop and a long beacon stem that contains the transcription factor binding site. The initially single-stranded hairpin AP-1 dODN quickly hybridizes to itself representing the active double-stranded ODN subsequently modulating effective gene expression.\textsuperscript{38,57}

The dODNs sequences were cloned into a pDS backbone under the control of H1 promoter in a beating state, potentially reducing the detrimental effect of cold storage,\textsuperscript{55} and can be used to transport donor hearts in this state.\textsuperscript{56} In conclusion, our study offers a therapeutic approach centered on AAV-mediated long-term delivery of RNA hairpin dONs neutralizing AP-1 transcriptional activity, which effectively reduced vascular lesion severity.

The dODNs sequences were cloned intro a pDS backbone under the control of H1 promoter under the control of H1 promoter in a beating state, potentially reducing the detrimental effect of cold storage,\textsuperscript{55} and can be used to transport donor hearts in this state.\textsuperscript{56} In conclusion, our study offers a therapeutic approach centered on AAV-mediated long-term delivery of RNA hairpin dONs neutralizing AP-1 transcriptional activity, which effectively reduced vascular lesion severity.

AAV9 vectors\textsuperscript{31} were generated by co-transfection of adenoviral helper plasmid pDGΔVP, the endothelial-specific AAV9 capsid variant pSe18VD2/9-SLRSPPS and either genome plasmid pDS-H1-hpAP1cons-CMV-EGFP or -hpAP1mut. AAV9SLR vectors were then purified using iodixanol step gradient ultracentrifugation as described previously.\textsuperscript{58-60} Genomic titers were determined by quantitative real-time PCR.\textsuperscript{58,61}

Assessment of AP-1 dODN Specificity

A sandwich ELISA-based method was employed to test the binding affinity of the hpAP-1 dODNs (Active Motif, Carlsbad, CA,
USA). The plots were generated by employing consensus and mutated dODNs in concentrations ranging from 0.1 pmol/L to 0.1 μmol/L. A nuclear extract isolated from 12-O-tetradecanoyl-phorbol-13-acetate (TPA)-stimulated K-562 cells was used as positive control for AP-1 transcriptional activation (Active Motif, Carlsbad, CA, USA). The graphs were achieved by plotting the logarithmic concentration of decoy ODNs against the absorbance, which was measured spectrophotometrically at 450 nm after performing the substrate reaction (Tecan, Crailsheim, Germany, USA).

Figure 6. Decreased Pro-inflammatory Markers in Aortic Grafts Transduced with AAV9SLR-Expressing hpAP-1 cons dONs. (A–C) Box-and-whisker plots of quantitative real-time PCR analysis of MCP-1 (A), IL-6 (B), and IFN-γ (C) in the depicted treatment groups. (D–G) Representative images showing IL-6 (D) and MCP-1 (F) protein levels after transduction and corresponding box-and-whisker plots of the relative fluorescence intensity (E and G). Nuclei were stained with DAPI (blue), and elastin autofluorescence was recorded in the green channel. Scale bar represents 25 μm. Horizontal bars in the boxes indicate median values, boxes indicate interquartile range, and whiskers indicate range of non-outlier values (*p < 0.05; **p < 0.01, n = 14 for control, n = 7 for AAV hpAP-1 mut, n = 9 for AAV hpAP-1 cons).
Fluorescence In Situ Hybridization and Determination of Transduction Efficacy

Fluorescence in situ hybridization (FISH) was performed to detect the intracellularly formed hairpin AP-1 dON in the graft tissue according to standard protocols.62 A molecular beacon (Biomers, Ulm, Germany) with complementary sequence to the hairpin AP-1 dODNs was used as a probe. In a hybridized state, the molecular beacon itself does not emit fluorescence signal due to the dye (5'-Cy5) and the quencher (3'-black hole quencher, BHQ) being located proximally. After hybridization to the target sequence, red fluorescence was recorded using confocal microscopy (LSM 800, Zeiss, Oberkochen, Germany). To quantify the percentage of hp AP-1 dON-transduced cells in the aortic tissue, four representative fields per section and two sections per graft were examined under ×20 magnification using a confocal microscope (LSM 800, Zeiss, Oberkochen, Germany). The number of AP-1 beacon-positive cells was divided by the number of DAPI-stained nuclei to determine the percent positive transduction. Approximately 1,000 cells were counted from each graft.

Heterotropic Aortic Transplantation

All animal experiments were performed with permission of the local animal welfare committee (Regional Council Karlsruhe, Germany, permission number G100/14) and conform to the guidelines from Directive 2010/63/EU of the European Parliament on the protection of animals used for scientific purposes or the current NIH guidelines. Female DBA/2 (H-2d) and C57BL/6J (H-2b) mice ages of 6–12 weeks were used as donor and recipient mice, respectively. The animals were purchased from Janvier Labs, Germany, and housed in the interfaculty biomedical research facility (IBF), Heidelberg University, Germany.

Descending thoracic aortae of DBA/2 mice were transplanted into C57CL/6 mice in infrarenal position, as already described.63 Donor
mice were euthanized with CO₂. Thoracic cavity was opened, left ventricle was punctured and the arterial circulatory system was perfused with 5 mL NaCl (4°C, 0.9%, Braun, Melsungen, Germany). Descending aorta was harvested and incubated for 30 min in NaCl (B. Braun, Melsungen, Germany) as control or 50 µL AAV9SLR solution (10^{12} vector genomes [VG]/mL), respectively.

Recipient C57BL/6J mice were anesthetized by inhalation of 5% isoflurane. Novalgin (500 mg/mL novaminsulfon-ratiopharm, Germany; 200 mg/kg body weight) and Carprieve (50 mg/mL carprofen, Norbrook Laboratories, Northern Ireland; 5 mg/kg body weight) were injected intraperitoneally. The abdominal cavity of recipient mice was opened and the infrarenal aorta was dissected. Titanium clips were applied and the aorta was transected. Grafts were connected to recipient aorta with two end-to-end anastomoses (Prolene 11-0, nylon black, S&T, Neuhausen, Switzerland). After removal of the clips the graft was re-perfused. Cyclosporine A (10 mg/kg body weight, Sandimmun, Novartis) and Temgesic (buprenorphin, 0.05 mg/kg body weight) for analgesia and CsA (10 mg/kg body weight, Sandimmun, Novartis) were injected intraperitoneally. Novalgin (500 mg/mL novaminsulfon-ratiopharm, Germany; 200 mg/kg body weight) and Carprieve (50 mg/mL carprofen, Norbrook Laboratories, Northern Ireland; 5 mg/kg body weight) were injected every 8 h within the first 3 postoperative days. CsA was injected once daily for 30 days; afterward, mice were sacrificed and aortic tissues were explanted.

**Morphometric Analysis**

7-µm thick frozen aortic sections (Microtom, HM 500 O, Walldorf, Germany) were randomly chosen from various intervals throughout the transplanted grafts and further stained with H&E according to standard protocols. Afterward, ImageJ (Fiji version 1.51p, NIH, Germany) were randomly chosen from various intervals throughout the transplanted grafts and further stained with H&E according to standard protocols. Afterward, ImageJ (Fiji version 1.51p, NIH, USA) was used to measure neointimal and medial areas with two investigators blinded toward the treatment regimen. The ratio of the two analyzed parameters was used as a measure of lumen obstruction.

**Immunohistochemistry**

Subsequent to fixation with paraformaldehyde (PFA) 4%, 5-µm thick aortic sections were incubated with BSA 2.5% and further with antibodies recognizing the markers of interest: α-SMA, MCP-1, MMP2, MMP9, IL-6, VCAM-1, Sca-1, c-Jun (phospho S63) (Abcam, Cambridge, UK), cyclin D2 (Biozol, Eching, Germany), ICAM-1 (Santa Cruz, Heidelberg, Germany), F4/80 (Dianova, Hamburg, Germany), and JNK (Invitrogen, Carlsbad, CA, USA). After a series of washing with PBS, incubation with corresponding secondary antibodies (Dianova, Hamburg, Germany) was performed, followed by counterstaining with nuclear DAPI. Fluorescent signals were detected using confocal microscopy (LSM 800, Zeiss, Oberkochen, Germany) and quantified using ImageJ. Four random regions per section and two sections per graft were analyzed.

**qRT-PCR**

Total RNA was extracted from isolated aortic grafts using RNaseasy mini kit (QIAGEN, Hilden, Germany) according to manufacturer’s instructions. First-strand cDNA synthesis was performed employing Omniscript reverse transcriptase kit (QIAGEN) and OligoT primers (Promega, Mannheim, Germany). qPCR was carried out on a standard SYBR Green (QIAGEN, Hilden, Germany)-based protocol using specific primers for the genes of interest, as follows: MCP-1 forward, 5'-TTTCCTCCACCAACCATGCAG-3'; MCP-1 reverse, 5'-CCAGCCGGCAACTGTGAG-3'; IL-6 forward, 5'-CTCTGGTCTCTTGAGTAACC-3'; IL-6 reverse, 5'-ACTCTCTCTGACTCCAGC-3'; RPL32 forward, 5'-GGAGACCAAAGAAAAACCA-3'; RPL32 reverse 5'-ATTGTTGGACCAAAGACTTG-3'.

**Data Analysis**

Data are shown as mean ± SD. GraphPad Prism 7 software was used to assess statistical significance between the groups, and one-way ANOVA analysis was employed to compare the different treatment groups. The Shapiro-Wilk test was used to prove that the results have a normal distribution. Tukey’s multiple-comparison test was employed as a post hoc test to compare difference between single groups. A p value lower than 0.05 was considered statistically significant.
