Abstract: As an important supplementary material to graphene in the optoelectronics field, molybdenum disulfide (MoS$_2$) has attracted attention from researchers due to its good light absorption capacity and adjustable bandgap. In this paper, MoS$_2$ layers are respectively grown on SiO$_2$/Si and sapphire substrates by atmospheric pressure chemical vapor deposition (APCVD). Atomic force microscopy, optical microscopy, and Raman and photoluminescence spectroscopy are used to probe the optical properties of MoS$_2$ on SiO$_2$/Si and sapphire substrates systematically. The peak shift between the characteristic A$_{1g}$ and E$_{12g}$ peaks increases, and the I peak of the PL spectrum on the SiO$_2$/Si substrate redshifts slightly when the layer numbers were increased, which can help in obtaining the layer number and peak position of MoS$_2$. Moreover, the difference from monolayer MoS$_2$ on the SiO$_2$/Si substrate is that the B peak of the PL spectrum has a blueshift of 56 meV and the characteristic E$_{12g}$ peak of the Raman spectrum has no blueshift. The 1- and 2-layer MoS$_2$ on a sapphire substrate had a higher PL peak intensity than that of the SiO$_2$/Si substrate. When the laser wavelength is transformed from 532 to 633 nm, the position of I exciton peak has a blueshift of 16 meV, and the PL intensity of monolayer MoS$_2$ on the SiO$_2$/Si substrate increases. The optical properties of MoS$_2$ can be obtained, which is helpful for the fabrication of optoelectronic devices.

Keywords: MoS$_2$; optical properties; Raman spectrum; PL spectrum; AFM

1. Introduction

Graphene has been researched extensively due to its many excellent properties, making it one of the most promising two-dimensional materials [1–3]. However, the Dirac energy states at the K point of the graphene Benelux region are in contact with each other, which limit the application of graphene in optoelectronics [4,5]. To compensate for the lack of band gap, researchers have focused their attention on the transition metal dichalcogenides (TMDs). Molybdenum disulfide (MoS$_2$) has similar physical properties to graphene, but it contains some advantages that graphene cannot match [6–9]. The monolayer MoS$_2$ is a “sandwich” structure, whereby the upper and lower layers are the hexagonal planes composed of sulfur atoms, and the middle is a layer of metal molybdenum atoms. Each molybdenum atom in the layer bonds with six sulfur atoms through covalent bonding to form the Mitsubishi columnar coordination structure. Meanwhile, each sulfur atom combines with three molybdenum atoms through covalent bonding. The multilayer or block MoS$_2$ with an interlayer...
distance of 0.65 nm is made up of monolayer MoS\textsubscript{2}, which is combined by the weak van der Waals force [10,11]. The band gap of MoS\textsubscript{2} increases with its thickness decreases, especially when it is reduced to the monolayer, and the band gap changes from the indirect band gap to the direct band gap [12]. In addition, monolayer MoS\textsubscript{2} has a high electron mobility and luminous efficiency, so it can be used in photovoltaic fields, such as in field effect transistors and sensors [13].

MoS\textsubscript{2} is a layered semiconductor material with strong light absorption, so it can be applied to photoluminescence, photovoltaic, and photocatalytic research [14]. The layer number and substrate environment would have a great influence on the electronic structure, physical, and optical properties of MoS\textsubscript{2}, which would also affect the performance of the optical device [15]. At present, there are few studies on the optical properties of MoS\textsubscript{2}. Therefore, the use of MoS\textsubscript{2} on SiO\textsubscript{2}/Si and sapphire substrates under different laser wavelengths and powers has been researched in an attempt to understand the luminescence laws of MoS\textsubscript{2}.

In this paper, different layers of MoS\textsubscript{2} are grown on SiO\textsubscript{2}/Si and sapphire substrates by atmospheric pressure chemical vapor deposition (APCVD) [16]. The effects of different laser wavelengths, powers, layer number, and substrate on the optical properties of MoS\textsubscript{2} are researched by the optical microscopy (OM), Raman spectroscopy (Raman), photoluminescence spectroscopy (PL), and atomic force microscopy (AFM), systematically, to master the luminescence laws. First, spectral characteristics of monolayer MoS\textsubscript{2} on the SiO\textsubscript{2}/Si and sapphire substrates are each studied; then, spectral characteristics of MoS\textsubscript{2} with different layers on the SiO\textsubscript{2}/Si and sapphire substrates are also tested; subsequently, the spectral properties of MoS\textsubscript{2} with different layers under different excitation wavelengths are researched; finally, the optical characteristic laws of MoS\textsubscript{2} are summarized, which can help in the fabrication of optoelectronic devices.

2. Experimental Methods

The specific experiment processes are as follows: single crystal sapphire substrate (C<0001>, 99.999\%, and hexagonal lattice structure, 6Carbon Technology, Shenzhen, China), and silicon substrate with a thickness of 285 nm silicon dioxide (6Carbon Technology, Shenzhen, China) are selected in this experiment. Firstly, the SiO\textsubscript{2}/Si and sapphire substrates were sequentially placed in acetone, deionized water, absolute ethanol, and deionized water for ultrasonic cleaning for 10, 5, 10, and 5 min, respectively, and dried with nitrogen gas gun [17,18]. Then, 100 mg sulfur powder (99.5\%, Alfa Aesar, Shanghai, China) and 2 mg molybdenum trioxide powder (MoO\textsubscript{3}, 99.95\%, Alfa Aesar, Shanghai, China) were separately weighed using an electronic analytical balance and each placed into two different quartz boats. The quartz boat containing sulfur powder was placed in the upstream low-temperature zone center of the tube furnace. Subsequently, substrate was placed, face-down, at 5 cm downstream from the MoO\textsubscript{3} powder for, and then the quartz boat with face-down substrate and MoO\textsubscript{3} powder was placed in the downstream high-temperature zone center of the tube furnace. The specific location of the experimental material is shown in Figure 1a. Afterwards, high-purity argon gas (99.999\%) with a flow rate of 200 sccm was introduced into the quartz tube for 10 min to remove the air of the tube furnace [19]. Figure 1b shows the reaction temperature change, and the temperature in the low-temperature zone was set to 200 °C, and the heating rate was 4.38 °C/min. At the same time, the temperature in the high-temperature zone was set to 720 °C, and the heating rate was 17.5 °C/min. The growth time of sapphire and SiO\textsubscript{2}/Si substrate were maintained for 5 and 10 min under the growth temperature of 720 °C, respectively. Finally, the temperature of the tube furnace was cooled to room temperature naturally after the growth reaction was complete.

Different layer numbers of MoS\textsubscript{2} on SiO\textsubscript{2}/Si and sapphire substrates were systematically characterized by OM, AFM, and Raman and PL spectroscopy [20]. The test characterization experiment of MoS\textsubscript{2} was the high-resolution Raman spectroscopy of LabRam HR Evolution model (HORIBA Jobin Yvon, Paris, France) using a high-definition color camera, which can achieve all functions of a standard microscope. Under the premise of maintaining constant room temperature, the specific test conditions of Raman spectroscopy are as follows: laser wavelength of 532 and 633 nm; spot diameter of 1 μm;
spectral resolution $\leq 0.65 \text{ cm}^{-1}$; scan time of 5 s; and the accumulation number of 3 s. In addition, the AFM (Dimension Icon, NanoScope8.10, Beijing, China) with 2% scanning accuracy error was also used to explore the size, thickness, surface morphology, and properties of MoS$_2$ grown on sapphire and SiO$_2$/Si substrates [21].

### 3. Results and Discussion

#### 3.1. Monolayer MoS$_2$ on Sapphire Substrate and SiO$_2$/Si Substrates

The SiO$_2$/Si and sapphire substrates are suitable substrate materials for growing high-quality, large-area, uniform triangles of MoS$_2$. In addition, the surface topography of MoS$_2$ on the SiO$_2$/Si and sapphire substrates can easily be observed by optical microscopy.

Raman spectroscopy can determine the layer number, layer stress, and doping level of MoS$_2$, so the Raman spectrum can further help us to master the structural characteristics of MoS$_2$. In Figure 2a, the Raman spectrum peak of monolayer MoS$_2$ on a sapphire substrate is much weaker than that on the SiO$_2$/Si substrate; the reason is that the sapphire substrate is transparent, and the Raman spectrum collects the reflected light from MoS$_2$. It can be seen from Figure 2b that the PL spectrum of MoS$_2$+sapphire is formed by the combination between monolayer MoS$_2$ and sapphire substrate. The B peak corresponds to the direct jump of B exciter due to the valence band splitting at the K point in the Brillouin zone [22]. The B peak of MoS$_2$+sapphire PL spectrum is much stronger than that of a pure sapphire substrate, which can be explained by the strong coupling between MoS$_2$ and sapphire substrate, and the efficient energy transfer occurs in MoS$_2$ samples on the sapphire substrate.

![Figure 2. (a) Raman spectrum of monolayer MoS$_2$ on SiO$_2$/Si and sapphire substrates; (b) PL spectrum of MoS$_2$+sapphire and sapphire substrate at the 532 nm laser wavelength.](image)
3.2. Characterization of Monolayer MoS$_2$ on SiO$_2$/Si Substrate

In Figure 3a, the Gauss–Lorentz function is used to fit the Raman spectrum. There are two characteristic peaks in the Raman spectrum, the E$_{12g}$ and A$_{1g}$ peak, and the peak shift difference between E$_{12g}$ and A$_{1g}$ was 20 cm$^{-1}$, and the ratio A$_{1g}$/E$_{12g}$ = 1.052 $\approx$ 1, which can help in establishing that the MoS$_2$ sample is monolayer.

Figure 3. (a) Raman spectrum of four different points in monolayer MoS$_2$ on a SiO$_2$/Si substrate; (b) PL spectrum of four different points in monolayer MoS$_2$ on a SiO$_2$/Si substrate; (c) PL spectrum of monolayer MoS$_2$ on a SiO$_2$/Si substrate with different laser power; (d) Raman spectrum of monolayer MoS$_2$ on a SiO$_2$/Si substrate with different laser power; (e) Optical micrograph of monolayer MoS$_2$ on a SiO$_2$/Si substrate; (f) AFM morphology of monolayer MoS$_2$ on a SiO$_2$/Si substrate; (g) Height profile of monolayer MoS$_2$ on a SiO$_2$/Si substrate.
There exist I and B exciton peaks on a SiO$_2$/Si substrate, and the PL spectrum of monolayer MoS$_2$ is dominated by free exciton transition luminescence at room temperature.

$$E = h \times H = \frac{h}{k} \times \frac{c}{\lambda} = \frac{1243}{\lambda}$$ (1)

The Planck constant, wavelength, energy, constant, and light speed are respectively represented by the symbols $h$, $\lambda$, $E$, $k$, and $c$ in Equation (1), and the units of $h$, $\lambda$, $E$, $k$, and $c$ are J.s, nm, eV, J/eV, and nm/s, respectively. According to the conversion relationship between photon energy and laser wavelength [23], it can be found from Figure 3b that the strongest photoluminescence peak is at 692.3 nm, and the corresponding photon energy is about 1.8 eV. In addition, a B exciton peak exists near 2.0 eV due to energy band splitting, which is the same as the reported band gap of monolayer MoS$_2$ [24]. In Figure 3c, the I exciton peak is dominant in PL spectrum intensity under the low excitation power. Meanwhile, the B exciton peak position and I exciton peak shape did not change much when the excitation power increased, but the shape of the B exciton peak changed significantly. Moreover, the relative position between the I exciton peak and B exciton peak was redshifted to some extent when the laser power increases, which can be explained by the introduction of n-type doping MoS$_2$ on the SiO$_2$/Si substrate. Figure 3d shows the Raman spectrum of monolayer MoS$_2$ with different laser power. When the laser power was increased, the Raman spectrum peak intensity increased, and the $E_{12g}$ characteristic peak was blueshifted. The reason is that the MoS$_2$ grown on the SiO$_2$/Si substrate is an n-type doped semiconductor [25]. Figure 3e shows the uniform triangular monolayer MoS$_2$ with a side length of 50 µm on the SiO$_2$/Si substrate, which is much larger than monolayer MoS$_2$ obtained by the mechanical peeling method [26]. In addition, the surface color of monolayer MoS$_2$ is uniform, which is in sharp contrast with the color of the SiO$_2$/Si substrate, so it can be determined that the MoS$_2$ sample is monolayer. It also can be seen from Figure 3f,g that triangular MoS$_2$ has a very uniform color, and the thickness is 0.76 ± 0.015 nm, which can also indicate that the grown MoS$_2$ is monolayer.

3.3. Characterization of Monolayer MoS$_2$ on Sapphire Substrate

In Figure 4a, the characteristic Raman peak position difference of monolayer MoS$_2$ on a sapphire substrate is 19.8 cm$^{-1}$, and $A_{1g}/E_{12g} \approx 1.051$, which is basically the same as the Raman spectrum of monolayer MoS$_2$ on a SiO$_2$/Si substrate. As shown in Figure 4b, the B peak of the PL spectrum on the sapphire substrate has a blueshift of 56 meV compared to the n-type doped monolayer MoS$_2$ on the SiO$_2$/Si substrate. The reason is that the sapphire substrate does not introduce any doping into the MoS$_2$, and the optical transition process was dominated by neutral exciton radiation. It can be found by observing Figure 4c that the photoluminescence peaks at 671 and 693 nm correspond to the B exciton peak and the sapphire substrate, respectively, and the PL intensity of monolayer MoS$_2$ is proportional to the laser power, which indicates that the monolayer MoS$_2$ on the sapphire substrate did not undergo saturation absorption. This is because there was no charged impurity on the surface of the sapphire substrate, so no doping was introduced into MoS$_2$ [27,28]. Figure 4d shows the Raman spectrum of monolayer MoS$_2$ on the sapphire substrate at different laser powers. The Raman spectrum peak intensity increases with laser power increases. Unlike the SiO$_2$/Si substrate, the characteristic $E_{12g}$ peak does not exist in the blueshift since the sapphire substrate does not introduce any doping into the monolayer MoS$_2$. In Figure 4e, the shape of monolayer MoS$_2$ is triangular, and the size can be up to 30 µm. As shown in Figure 4f,g, the triangular MoS$_2$ has uniform color, and the thickness of MoS$_2$ is about 0.83 ± 0.017 nm, which indicates that the MoS$_2$ sample is monolayer.
Figure 4. (a) Raman spectrum of four different points in monolayer MoS$_2$ on a sapphire substrate; (b) PL spectrum of four different points in monolayer MoS$_2$ on a sapphire substrate; (c) PL spectrum of monolayer MoS$_2$ on a sapphire substrate at different laser powers; (d) Raman spectrum of monolayer MoS$_2$ on a sapphire substrate at different laser powers; (e) Optical micrograph of monolayer MoS$_2$ on a sapphire substrate; (f) AFM morphology of monolayer MoS$_2$ on a sapphire substrate; (g) Height profile of monolayer MoS$_2$ on a sapphire substrate.
3.4. Characterization of Different Layers of MoS\textsubscript{2} on SiO\textsubscript{2}/Si Substrate

In order to analyze the lattice vibration modes, the Raman and PL spectrums of different layer MoS\textsubscript{2} on the SiO\textsubscript{2}/Si and sapphire substrates were tested. In Figure 5a, the greater the layer number of MoS\textsubscript{2}, the brighter the color under the microscope, which indicates the presence of MoS\textsubscript{2} with different layer numbers on the surface of the SiO\textsubscript{2}/Si substrate. From bulk to monolayer samples, MoS\textsubscript{2} had two distinct characteristic peaks in the range of 300–450 cm\textsuperscript{-1}: E\textsuperscript{12g} and A\textsubscript{1g} peaks. The E\textsuperscript{12g} peak corresponds to the vibration of Mo atom and S atom parallel to the layer, and the A\textsubscript{1g} peak corresponds to the vibration of S atom perpendicular to the layer. The E\textsuperscript{12g} peak with in-plane vibration mode is redshifted when the number of layers of MoS\textsubscript{2} increase; this is because the short-range van der Waals force is stronger than dielectric shielding of the long-range Coulomb interaction. Meanwhile, the A\textsubscript{1g} peak of out-of-plane vibration mode has blueshifted with the gradual decrease of van der Waals force [29]. It can be seen from Figure 5b that the photoluminescence of the 2-layer and 3-layer MoS\textsubscript{2} can also be observed due to the interaction between the layers. The B peak and I peak of monolayer MoS\textsubscript{2} are respectively located at 627 and 677 nm. The I peak of the PL spectrum corresponds to direct exciton transition at the K point of Brillouin zone, and the B peak corresponds to the B exciton peak direct transition, which is caused by the valence band splitting. The I peak exists and is slightly redshifted when the MoS\textsubscript{2} layer number increases; this is because the electron band gap at the K point of the Brillouin zone decreases, and the increase in interlayer van der Waals forces. In addition, the PL intensity increases gradually when the MoS\textsubscript{2} layer number decreases. Therefore, monolayer MoS\textsubscript{2} has the highest PL quantum yield, which is related to the phonon-dependent carrier band relaxation [30].

$$\eta_{\text{Lum}} \approx \frac{K_{\text{rad}}}{(K_{\text{rad}} + K_{\text{defect}} + K_{\text{relax}})}$$  \hspace{1cm} (2)

The $K_{\text{rad}}$, $K_{\text{defect}}$, and $K_{\text{relax}}$ in Formula (2) refer to the radiation recombination rate, defect trapping rate, and carrier relaxation rate, respectively. The $K_{\text{relax}}$ decreases as the indirect band gap width increases, which leads to an increase in the luminescence intensity and an essential change in the electronic structure of MoS\textsubscript{2}. Therefore, the monolayer MoS\textsubscript{2} is $K_{\text{relax}} = 0$. Figure 5c shows the optical micrograph of MoS\textsubscript{2} with different layer numbers on the SiO\textsubscript{2}/Si substrate. The triangular shape of MoS\textsubscript{2} has a distinct color contrast with the SiO\textsubscript{2}/Si substrate, and the size can be up to 30 μm. As shown in Figure 5d,e, the color of triangular MoS\textsubscript{2} is not uniform, and the thickness of middle MoS\textsubscript{2} is about 2.87 ± 0.057 nm, which indicates that the grown MoS\textsubscript{2} is a multilayer.

3.5. Characterization of Different Layers MoS\textsubscript{2} on Sapphire Substrate

In Figure 6a, the interlayer van der Waals force increases gradually with the increase of MoS\textsubscript{2} layer number, which would result in an increase of the mechanical constant and redshifting of the A\textsubscript{1g} peak. Meanwhile, the the characteristic E\textsuperscript{12g} peak redshifts to some extent; this is because long-range Coulomb interactions play a more prominent role in the control of the atomic vibration when the MoS\textsubscript{2} layer numbers increase. Therefore, the frequency shift difference between the characteristic E\textsuperscript{12g} and A\textsubscript{1g} peaks on the sapphire substrate increase monotonically with the increase of MoS\textsubscript{2} layer number. It is not difficult to find, when observing Figure 6b, that the bulk of the MoS\textsubscript{2} on the sapphire substrate does not exist in the PL peak. When the MoS\textsubscript{2} layer number decreases, MoS\textsubscript{2} change from an indirect band gap to direct band gap, and the PL intensity increases gradually, so the PL intensity of monolayer MoS\textsubscript{2} can be up to its maximum value. The B peak of monolayer MoS\textsubscript{2} exists in the blueshift region, slightly, due to the annihilation of the phonon-assisted decay channel. The 1- and 2-layer MoS\textsubscript{2} on the sapphire substrate has a higher PL peak intensity than that of 1- and 2-layer MoS\textsubscript{2} on the SiO\textsubscript{2}/Si substrate. The reason is that the relative dielectric constant of the sapphire substrate is higher than that of the SiO\textsubscript{2}/Si substrate, which would result in the higher dielectric shielding effect. Figure 6c shows the optical micrograph of MoS\textsubscript{2} with different layers on the sapphire substrate, where the size of MoS\textsubscript{2} triangles are mainly 20 μm, and the surface of MoS\textsubscript{2} sample is relatively clean and uniform, which is in sharp contrast with the sapphire substrate. As shown in Figure 6d,e,
the color and thicknesses of triangular MoS$_2$ are not uniform, and the middle thickness of MoS$_2$ is about $2.93 \pm 0.059$ nm, which indicates that the MoS$_2$ sample is multilayered.
than that of multilayer and bulk MoS$_2$. The reason the PL intensity increases with decreasing MoS$_2$ layer number is that the decrease of relaxK and the luminescence resonance state can match the direct exciton transfer. The PL phenomenon of monolayer MoS$_2$ is an inherent property which is not caused by external disturbances.

Figure 6. (a) Raman spectrum of MoS$_2$ with different layers on a sapphire substrate; (b) PL spectrum of MoS$_2$ with different layers on a sapphire substrate; (c) Optical micrograph of MoS$_2$ with different layers on a sapphire substrate; (d) AFM morphology of multilayer MoS$_2$ on a sapphire substrate; (e) Height profile of multilayer MoS$_2$ on a sapphire substrate.

3.6. Characterization of MoS$_2$ with Different Layers on Sapphire Substrate Under the 633 nm Laser Wavelength

In Figure 7a, the Raman spectrum of MoS$_2$ with different layers on the sapphire substrate under the 633 nm laser wavelength, and the peak position of the MoS$_2$ Raman spectrum are closely related to its thickness. Due to the increase in van der Waals forces, the characteristic $E_{12g}^1$ peak blueshifted
while the characteristic $A_{1g}$ peak redshifted when the MoS$_2$ layer number increased. It was possible to
determine the layer number of MoS$_2$ according to the wavenumber difference of $A_{1g} - E_{12g}^\prime$. Due to
the very small local field effect, monolayer MoS$_2$ had the strongest PL intensity. As shown in Figure 7b,
the luminescence quantum efficiency of monolayer MoS$_2$ was much higher than that of multilayer
and bulk MoS$_2$. The reason the PL intensity increases with decreasing MoS$_2$ layer number is that the
decrease of $K_{elax}$ and the luminescence resonance state can match the direct exciton transfer. The PL
phenomenon of monolayer MoS$_2$ is an inherent property which is not caused by external disturbances.

![Figure 7](image1.jpg)

**Figure 7.** (a) Raman spectrum of MoS$_2$ with different layers on the sapphire substrate; (b) PL spectrum
of MoS$_2$ with different layer on the sapphire substrate under the laser wavelength of 633 nm.

### 3.7. Characterization of Monolayer MoS$_2$ on SiO$_2$/Si Substrate Under the 633 nm Laser Wavelength

The Raman spectrum of monolayer MoS$_2$ on the SiO$_2$/Si substrate was also tested under 633 nm
laser wavelength, and the spectrum curve was fitted using the Gauss–Lorentz function, as shown in
Figure 8a. The peak difference of monolayer MoS$_2$ between the characteristic $E_{12g}$ and $A_{1g}$ peaks was
20 cm$^{-1}$, which preliminarily established that MoS$_2$ was monolayer. It can be seen from Figure 8b that
the PL spectrum has its strongest peak intensity at 686.1 nm, and the corresponding photon energy is
1.81 eV, which is consistent with the absorption transition peak of I excitation. Compared to the PL
spectrum of monolayer MoS$_2$ at 532 nm, it can be found that the position of the I exciton peak has a
blueshift of 16 meV, and the PL intensity of monolayer MoS$_2$ increases when the laser wavelength
transforms from 532 to 633 nm. The reason is due to the transition of the upper energy level of spin
cleavage valence band to the conduction band.

![Figure 8](image2.jpg)

633 nm (a) Raman spectrum; (b) PL spectrum.
4. Conclusions

In this paper, large size and high-quality MoS\textsubscript{2} layers were grown on the SiO\textsubscript{2}/Si and sapphire substrates by APCVD. The optical properties of MoS\textsubscript{2} on the SiO\textsubscript{2}/Si and sapphire substrates were researched systematically by atomic force microscopy, optical microscopy, and Raman and photoluminescence spectroscopy under different laser light wavelengths and powers. The peak shift between characteristic A\textsubscript{1g} and E\textsubscript{12g} peaks increased monotonously, and the I peak of the PL spectrum on the SiO\textsubscript{2}/Si substrate redshifted slightly when the layer number of MoS\textsubscript{2} was increased, which can help to obtain the layer number and peak position of MoS\textsubscript{2}. In addition, the effects of layer number and external substrate environment on the optical properties of MoS\textsubscript{2} were also studied systematically. The difference from monolayer MoS\textsubscript{2} on the SiO\textsubscript{2}/Si substrate is that the B peak of the PL spectrum had a blueshift of 56 meV and the characteristic E\textsubscript{12g} peak of the Raman spectrum had no blueshift. The 1- and 2-layer MoS\textsubscript{2} on the sapphire substrate has a higher PL peak intensity than that of the SiO\textsubscript{2}/Si substrate. When the laser wavelength transforms from 532 to 633 nm, the position of the I exciton peak had a blueshift of 16 meV, and the PL intensity of monolayer MoS\textsubscript{2} on a SiO\textsubscript{2}/Si substrate increased. The optical properties of MoS\textsubscript{2} can be obtained, which can pave the way for the fabrication of optoelectronic devices.
