In this manuscript, we introduce the concept of complex-valued triple controlled metric spaces as an extension of rectangular metric type spaces. To validate our hypotheses and to show the usability of the Banach and Kannan fixed point results discussed herein, we present an application on Fredholm-type integral equations and an application on higher degree polynomial equations.

1. Introduction

Since the breakthrough of Banach [1] in 1922, where he was able to show that a contractive mapping on a complete metric space has a unique fixed point, the field of fixed point theory has become an important research focus in the field of mathematics; see [2–6]. Due to the fact that fixed point theory has many applications in many fields of science, many researchers have been working on generalizing his result by either generalizing the type of contractions [7–10] or by extending the metric space itself (b-metric spaces [11, 12], controlled metric spaces [13], double controlled metric spaces [14], etc.). On the other hand, Azam et al. [15] defined complex-valued metric spaces and gave common fixed point results. Rao et al. [16] introduced the complex-valued b-metric spaces in the year 2013. Going in the same direction, recently, Ullah et al. [17] presented complex-valued extended b-metric spaces to extend the idea of extended b-metric spaces.

In this manuscript, following the path of the work done in [18], we extend complex-valued rectangular extended b-metric spaces [19] to complex-valued triple controlled metric spaces. The layout of our manuscript is as follows. In the second section, we present some backgrounds along with the definition of complex-valued triple controlled metric spaces. In the third section, we prove some fixed point results in such spaces. In the fourth section, we present an application for our findings. In closing, we present two open questions.

2. Preliminaries

In what follows, owing to Azam et al. [15], we recall several notations and definitions which will be used in the sequel.
Let $\mathbb{C}$ be the set of all complex numbers and $z_1, z_2 \in \mathbb{C}$. The partial order on $\mathbb{C}$ is defined as $z_1 \leq z_2$ if and only if $\text{Re}(z_1) \leq \text{Re}(z_2)$ and $\text{Im}(z_1) \leq \text{Im}(z_2)$. This implies that $z_1 \leq z_2$ if one of the below conditions is fulfilled:

(i) $\text{Re}(z_1) = \text{Re}(z_2), \text{Im}(z_1) < \text{Im}(z_2)$
(ii) $\text{Re}(z_1) < \text{Re}(z_2), \text{Im}(z_1) = \text{Im}(z_2)$
(iii) $\text{Re}(z_1) < \text{Re}(z_2), \text{Im}(z_1) < \text{Im}(z_2)$
(iv) $\text{Re}(z_1) = \text{Re}(z_2), \text{Im}(z_1) = \text{Im}(z_2)$

Following [15], the authors in [17] developed the notion of complex-valued extended $b$-metric spaces.

**Definition 1** (see [17]). Let $X$ be a nonempty set and $\xi : X \times X \to [1, \infty]$ be a function. Then, $L_\xi : X^2 \to \mathbb{C}$ is known as a complex-valued extended $b$-metric space if the following are satisfied for all $s, \kappa, u \in X$:

1. $0 \leq L_\xi(s, \kappa)$ and $L_\xi(s, s) = 0$ if and only if $s = \kappa$
2. $L_\xi(s, \kappa) = L_\xi(\kappa, s)$
3. $L_\xi(s, \kappa) \leq \xi(s, u)[L_\xi(s, u) + L_\xi(u, \kappa)]$

Then, the pair $(X, L_\xi)$ is known as a complex-valued extended $b$-metric space.

As an extension of complex-valued extended $b$-metric spaces, Ullah et al. in [19] introduced the concept of complex-valued rectangular extended $b$-metric spaces.

**Definition 2** (see [19]). Let $X$ be a nonempty set and $\xi : X^2 \to [1, \infty]$ and $L_r : X^2 \to \mathbb{C}$. We say that $(X, L_r)$ is a complex-valued rectangular extended $b$-metric space if for all $a, b \in X$ each of which is different from $\kappa, \upsilon \in X$, we have

1. $L_r(s, \kappa) = 0$ if and only if $s = \kappa$
2. $L_r(s, \kappa) = L_r(\kappa, s)$
3. $L_r(a, b) \leq \xi(a, b)[L_r(a, \kappa) + L_r(\kappa, \upsilon) + L_r(\upsilon, b)]$

The authors in [20] have recently introduced the notion of triple controlled metric type spaces.

**Definition 3** (see [20]). Let $X$ be a nonempty set. Given three functions $\xi, \rho, \varsigma : X^2 \to [1, \infty]$ and $L_r : X^2 \to [0, \infty)$. We say that $(X, L_r)$ is a triple controlled metric type space if for all $a, b, \kappa, \upsilon \in X$, we have

1. $L_r(s, \kappa) = 0$ if and only if $s = \kappa$
2. $L_r(s, \kappa) = L_r(\kappa, s)$
3. $L_r(a, b) \leq \xi(a, \kappa)L_r(a, \kappa) + \rho(\kappa, \upsilon)L_r(\kappa, \upsilon) + \varsigma(\upsilon, b)L_r(\upsilon, b)$

Highly motivated by the abovementioned concepts, we now present the definition of complex-valued triple controlled metric spaces.

**Definition 4**. Let $X$ be a nonempty set. Given three functions $\xi, \rho, \varsigma : X^2 \to [1, \infty)$ and $L_r : X^2 \to \mathbb{C}$. We say that $(X, L_r)$ is a complex-valued triple controlled metric space if for all $a, b \in X$, each of which is different from $\kappa, \upsilon \in X$, we have

1. $L_r(s, \kappa) = 0$ if and only if $s = \kappa$
2. $L_r(s, \kappa) = L_r(\kappa, s)$
3. $L_r(a, b) \leq \xi(a, \kappa)L_r(a, \kappa) + \rho(\kappa, \upsilon)L_r(\kappa, \upsilon) + \varsigma(\upsilon, b)L_r(\upsilon, b)$

Throughout the rest of this paper, we will denote a complex-valued triple controlled metric space by (CV-TCMS). Next, we present the topology of (CV-TCMS).

**Definition 5**. Let $(X, L_r)$ be a (CV-TCMS).

1. We say that a sequence $(a_n)$ is $L_r$-convergent to some $a \in X$ if $|L_r(a_n, a)| \to 0$ as $n \to \infty$
2. We say that a sequence $(a_n)$ is $L_r$-Cauchy if and only if $\lim_{n,m \to \infty} |L_r(a_n, a_m)| = 0$
3. We say that $(X, L_r)$ is $L_r$-complete if for every $L_r$-Cauchy sequence is $L_r$-convergent
4. Let $x \in X$. An open ball of center $x$ and radius $\eta > 0$ in the (CV-TCMS) $(X, L_r)$ is $L_r(x, \eta) = \{b \in X | L_r(x, b) < \eta\}$

Note that a CV rectangular metric space is a CV-TCMS. The converse is not true. Next, we present an example that confirms this statement.

**Example 1**. Let $X = \mathbb{Y} \cup \mathbb{Z}$ where $\mathbb{Y} = \{(1/k) | k \in \mathbb{N}\}$ and $\mathbb{Z}$ is the set of positive integers. We define $L_r : X^2 \to \mathbb{C}$ by

$$L_r(a, b) = \begin{cases} 0, & \text{if } a = b \\ 2i\beta, & \text{if } a, b \in \mathbb{Y} \\ i\beta \overline{a}, & \text{otherwise,} \end{cases}$$

where $\beta > 0$. Now, define $\xi : X^2 \to [1, \infty)$ by $\xi(a, b) = 4\beta$. Given $\rho : X^2 \to [1, \infty)$ as $\rho(a, b) = 3\beta$ and $\varsigma : X^2 \to [1, \infty)$ as $\varsigma(a, b) = \max \{a, b\} + 2\beta$.

Note that $(X, L_r)$ is a CV-TCMS. On the other hand, $(X, L_r)$ is not a CV rectangular metric space. Indeed,

$$L_r\left(\frac{1}{\overline{3}}, \frac{1}{\overline{3}}\right) = 2i\beta > L_r\left(\frac{1}{\overline{3}}, \frac{1}{2}\right) + L_r\left(2, \frac{1}{3}\right) + L_r\left(\frac{1}{3}, \frac{1}{3}\right) = \frac{3i\beta}{2}.$$
In this paper, we prove the Banach and Kannan fixed point results in the setting of CV-TCMSs. Two related applications are also investigated.

3. Main Results

Theorem 1. Let \((X, L_t)\) be a \(L_t\)-complete CV-TCMS. Let \(T : X \rightarrow X\) satisfy \(L_t(Tx, Ty) \leq \delta L_t(x, y)\) where \(0 \leq \delta < 1\). Assume that there exists \(x_0 \in X\) such that the sequence \(\{x_n\}\) defined by \(x_n = T^n x_0\) satisfies the following:

\[
\begin{align*}
\lim_{n \to \infty} \|x_n - x_{n+1}\| &\leq \frac{1}{\delta}, \\
\lim_{n \to \infty} \|T(x_n, x_{n+1})\| &\leq \frac{1}{\delta}, \\
\lim_{n \to \infty} \|T(x_n, y)\| &< \infty, \\
\sup_{m \geq 1} \lim_{n \to \infty} \|x_n - x_{n+1}\| &\leq \frac{1}{\delta}, \\
\sup_{m \geq 1} \lim_{n \to \infty} \|\rho(x_n, x_{n+1})\| &\leq \frac{1}{\delta}.
\end{align*}
\]

Then, \(T\) has a unique fixed point in \(X\).

Proof. First, we have \(L_t(x_n, x_{n+1}) \leq \delta L_t(x_{n-1}, x_n) \leq \delta^2 L_t(x_{n-2}, x_{n-1}) \leq \cdots \leq \delta^n L_t(x_0, x_1)\). Then,

\[
|L_t(x_n, x_{n+1})| \to 0 \text{ as } n \to \infty.
\]

Now, let \(L_i = L_t(x_{n+i}, x_{n+i+1})\). We need to consider the following two cases.

Case 1. Let \(x_n = x_m\) for some natural numbers \(n\) and \(m\) with \(n \neq m\). Without loss of generality, take \(m > n\). If \(\mathbb{T}^{m-n}(x_m) = x_n\); then, by choosing \(y = x_n\) and \(p = m - n\), we get \(\mathbb{T}^p y = y\), which implies that \(y\) is a periodic point of \(T\). Hence, \(L_i(y, \mathbb{T}^i y) = L_i(\mathbb{T}^{i+p} y, \mathbb{T}^{i+p}) \leq \delta^i L_i(y, \mathbb{T}^i y)\). Since \(\delta \in (0, 1)\), we get \(|L_i(y, \mathbb{T}^i y)| = 0\), so \(y = \mathbb{T}^i y\), that is, \(y\) has a fixed point.

From now on, we consider the following case.

Case 2. Assume that for all natural numbers \(n \neq m\), we have \(x_n = \mathbb{T}^m x_0 \neq \mathbb{T}^m x_0 = x_m\). Let \(n < m\). To prove that \(\{x_n\}\) is a \(L_i\)-Cauchy sequence, we need to consider the following two subcases.

Subcase 1. If \(m = n + p + 1\) (where \(p \geq 1\) is a fixed natural number), then by the rectangle inequality of the CV-TCMS, we have

\[
|L_i(x_n, x_{n+2p+1})| \leq \xi(x_n, x_{n+1}) L_i(x_{n+1}, x_{n+2}) + \rho(x_{n+1}, x_{n+2}) \cdot |L_i(x_{n+1}, x_{n+2})| + \xi(x_{n+2}, x_{n+2p+1}) L_i(x_{n+2}, x_{n+2p+1}) + \xi(x_n, x_{n+1}) L_i(x_{n+1}, x_{n+2}) + \rho(x_{n+1}, x_{n+2}) L_i(x_{n+1}, x_{n+2})\]

Now, given that

\[
\begin{align*}
\sup_{m \geq 1} \lim_{m \to \infty} \|x_n - x_{n+1}\| &\leq \frac{1}{\delta}, \\
\sup_{m \geq 1} \lim_{m \to \infty} \|\rho(x_n, x_{n+1})\| &\leq \frac{1}{\delta},
\end{align*}
\]

we can easily deduce that

\[
|L_i(x_n, x_{n+2p+1})| \leq \left[\delta^{-1} + \delta^{-1} + \sum_{i=1}^{p} \delta^{n+i} + \sum_{i=1}^{p} \delta^{n+i+1}\right] |L_0|.
\]

Since \(\lim_{m \to \infty} \delta^m = 0\), the last right-hand side goes to zero at the limit \(n \to \infty\) (for any integer \(p \geq 1\)). Therefore, \(\{L_i(x_n, x_{n+2p+1})\}\) is convergent.

Subcase 2. Let \(m = n + 2p\) (where \(p \geq 1\) is a fixed integer). First, notice the following:

\[
L_i(x_n, x_{n+2}) \leq \delta^2 L_i(x_{n-2}, x_n) \leq \cdots \leq \delta^n L_i(x_0, x_2),
\]
which leads us to conclude that
\[ |L_t(x_{n}, x_{n+1})| \longrightarrow 0 \text{ as } n \longrightarrow \infty. \] (9)

Thus, by Subcase 1 and using the rectangular inequality of the complex-valued triple controlled metric, we have
\[
|L_t(x_n, x_{n+2p})| \leq \xi(x_n, x_{n+2p-3})|L_t(x_{n+2-3}, x_{n+2p-3})| \\
+ \rho(x_{n+2p-3}, x_{n+2p})|L_t(x_{n+2p-3}, x_{n+2p-2})| \\
+ \zeta(x_{n+2p-2}, x_{n+2p})|L_t(x_{n+2p-2}, x_{n+2p})| \leq \xi(x_n, x_{n+1})\delta^n|L_0| \\
+ \rho(x_{n+1}, x_{n+2})\delta^{n+1}|L_0| + \sum_{l=1}^{p-1} \xi(x_{n+2l}, x_{n+2l+1}) \\
+ \zeta(x_{n+2l}, x_{n+2l+1})\delta^{n+2l+1}|L_0| + \sum_{l=1}^{p-1} \rho(x_{n+2l+1}, x_{n+2l+2}) \\
\cdot \zeta(x_{n+2l+2}, x_{n+2l+3})\delta^{n+2l+3}|L_0| + \zeta(x_{n+2p-2}, x_{n+2p})\delta^n|L_t(x_0, x_1)|. \] (10)

Now, similar to Subcase 1, one can easily deduce that \( \{L_t(x_n, x_{n+2p})\} \) is a convergent sequence as \( n \longrightarrow \infty \) (for any integer \( p \geq 1 \)). Hence, by Subcases 1 and 2, we conclude that \( \{x_n\} \) is a \( L_t \)-Cauchy sequence. Since \( (\mathcal{X}, L_t) \) is a \( L_t \)-complete CV-TCMS, there is \( v \in \mathcal{X} \) such that \( x_n \longrightarrow v \) as \( n \longrightarrow \infty \).

Now, if there exists \( N \in \mathbb{N} \) such that \( x_N = v \), then since we deal with Case 2, one writes \( x_n = T^nx_0 \neq v \) for all \( n > N \). Also, \( x_n = T^nx_0 \neq v \) for all \( n > N \). Next, assume that there exists \( N \in \mathbb{N} \) with \( x_N = T^nx_0 = v \). Once again, we confirm that \( x_n = T^nx_0 \in \{v, Tv\} \) for all \( n > N \). Thus, without loss of generality, we may assume \( x_n \in \{v, Tv\} \) for all natural numbers \( n \). We have
\[
L_t(v, Tv) \leq \xi(v, x_n)L_t(v, x_n) + \rho(x_n, x_{n+1})L_t(x_n, x_{n+1}) \\
+ \zeta(x_{n+1}, Tv)L_t(x_{n+1}, Tv) \leq \xi(v, x_n)L_t(v, x_n) \\
+ \rho(x_n, x_{n+1})L_t(x_n, x_{n+1}) + \zeta(x_{n+1}, Tv)\delta|L_t(x_n, v)|, \] (11)

which implies
\[
|L_t(v, Tv)| \leq \xi(v, x_n)|L_t(v, x_n)| + \rho(x_n, x_{n+1})|L_t(x_n, x_{n+1})| \\
+ \zeta(x_{n+1}, Tv)\delta|L_t(x_n, v)|. \] (12)

Therefore, in view of the assumptions in the theorem, as \( n \longrightarrow \infty \), we deduce that \( |L_t(v, Tv)| = 0 \) and that \( Tv = v \) as required.

In closing, assume there exist two fixed points of \( T \), say \( v \) and \( \mu \) where \( v \neq \mu \). Thus,
\[ L_t(v, \mu) = L_t(Tv, \mu) \leq \delta L_t(v, \mu) < L_t(v, \mu), \] (13)

which is a contradiction. Therefore, the fixed point of \( T \) is unique.

**Theorem 2.** Let \((\mathcal{X}, L_t)\) be a \( L_t \)-complete CV-TCMS and \( T \) be a self mapping on \( \mathcal{X} \) satisfying the following condition: for all \( a, b \in \mathcal{X} \), there exists \( 0 < \delta < 1/2 \) such that
\[ L_t(Ta, Tb) \leq \delta[L_t(a, Ta) + L_t(b, Tb)], \] (14)

and there exists \( x_0 \in \mathcal{X} \) in order that the sequence \( \{x_n\} \) defined by \( x_n = T^n x_0 \) satisfies the following:
\[ \lim_{n \longrightarrow \infty} \xi(y, x_n) \leq \frac{1}{\delta}, \] (15)

\[ \lim_{n \longrightarrow \infty} \zeta(x_n, y) \leq \frac{1}{\delta} \text{ for any } y \in \mathcal{X}, \]

\[ \lim_{n \longrightarrow \infty} \rho(x_n, x_{n+1}) \leq \frac{1}{\delta}. \]

Then, \( T \) has a unique fixed point in \( \mathcal{X} \).

**Proof.** First of all, note that for all \( n \geq 1 \), we have
\[ L_t(x_n, x_{n+1}) \leq \delta[L_t(x_{n-1}, x_n) + L_t(x_n, x_{n+1})]. \] (16)

Consequently,
\[ L_t(x_n, x_{n+1}) \leq \frac{\delta}{1 - \delta} L_t(x_{n-1}, x_n). \] (17)

Since \( 0 < \delta < 1/2 \), one has \( 0 < (\delta/(1 - \delta)) < 1 \). Set \( \mu = \delta/(1 - \delta) \). One writes
\[ |L_t(x_n, x_{n+1})| \leq \mu|L_t(x_{n-1}, x_n)| \leq \mu^2|L_t(x_{n-2}, x_{n-1})| \leq \cdots \leq \mu^n|L_t(x_0, x_1)|. \] (18)

Therefore,
\[ |L_t(x_n, x_{n+1})| \longrightarrow 0 \text{ as } n \longrightarrow \infty. \] (19)

Also, for all \( n, m \geq 1 \), we have
\[ L_t(x_n, x_m) \leq \delta[L_t(x_{m-1}, x_n) + L_t(x_{m-1}, x_m)]. \] (20)

By (19), we deduce that \( |L_t(x_n, x_m)| \longrightarrow 0 \) as \( n, m \longrightarrow \infty \). Hence, \( \{x_n\} \) is a \( L_t \)-Cauchy sequence. Since \( (\mathcal{X}, L_t) \) is a \( L_t \)-complete CV-TCMS, the sequence \( \{x_n\} \) converges to some \( v \in \mathcal{X} \).

By the argument of the proof of Theorem 1, assume that for all \( n \geq 1 \), we have \( x_n \in \{v, Tv\} \). Thus,
\[
L_t(v, Tv) \leq \xi(v, x_n)L_t(v, x_n) + \rho(x_n, x_{n+1})L_t(x_n, x_{n+1}) \\
+ \zeta(x_{n+1},Tv)L_t(x_{n+1},Tv) \leq \xi(v, x_n)L_t(v, x_n) \\
+ \rho(x_n, x_{n+1})L_t(x_n, x_{n+1}) + \zeta(x_{n+1},Tv)\delta|L_t(x_n, v)|. \] (21)
As $n \to \infty$, we obtain

$$|L_t(v, T v)| \leq 0 + 0 + \lim_{n \to \infty} \sup_{x \in X} |x^{n+1}, T v)\delta[L_t(v, T v)] < |L_t(v, T v)|.$$ \hspace{1cm} (22)

At the limit $n \to \infty$, we find that $|L_t(v, T v)| = 0$ and that $T v = v$ as required. Now, assume that we have two fixed points of $T$, say $v$ and $s$. Therefore,

$$|L_t(v, s)| = |L_t(T v, T s)| \leq \delta(|L_t(v, v)| + |L_t(s, s)|) = 0.$$ \hspace{1cm} (23)

Hence, $v = s$, as desired.

4. Applications

4.1 A Fredholm-Type Integral Equation. Consider the set $X = C([0, 1], \mathbb{R})$. Given the following Fredholm-type integral equation

$$a'(t) = \int_0^1 M(t, s, a'(t)) ds, \quad \text{for } t, s \in [0, 1],$$ \hspace{1cm} (24)

where $M(t, s, a'(t))$ is a continuous function from $[0, 1]^2$ into $\mathbb{R}$. Now, define

$$L_t : X \times X \to \mathbb{C}$$

$$(a, b) \mapsto i \sup_{t \in [0, 1]} \left( |a(t)| + |b(t)| \right).$$ \hspace{1cm} (25)

Note that $(X, L_t)$ is a complete CV-TCMS, where

$$\xi(a, b) = 2, \rho(a, b) = 1 \text{ and } \zeta(a, b) = 3.$$ \hspace{1cm} (26)

Theorem 3. Assume that for all $a, b \in X$

1. $|M(t, s, a'(t))| + |M(t, s, b(t))| \leq \delta(|a'(t)| + |b(t)|)$, for some $\delta \in [0, 1/4)$

2. $M(t, s, \int_0^t M(t, s, a'(t)) ds < M(t, s, a'(t))$ for all $t, s$

Then, the above integral equation has a unique solution.

Proof. Let $T : X \to X$ be defined by $Ta'(t) = \int_0^1 M(t, s, a'(t)) ds$. Then,

$$L_t(Ta', Tb) = i \sup_{t \in [0, 1]} \left( \frac{|Ta'(t)| + |Tb(t)|}{2} \right).$$ \hspace{1cm} (27)

Now, we have

$$L_t(Ta'(t), Tb(t)) = i \left( \frac{|Ta'(t)| + |Tb(t)|}{2} \right)$$

$$= \left( \frac{|\int_0^t M(t, s, a'(t)) ds| + |\int_0^t M(t, s, b(t)) ds|}{2} \right)$$

$$\leq \frac{1}{2} \left( \int_0^t \left( |M(t, s, a'(t))| + |M(t, s, b(t))| \right) ds \right)$$

$$\leq \frac{1}{2} \left( \int_0^t (|a'(t)| + |b(t)|) ds \right)$$

$$\leq \delta L_t(a'(t), b(t)).$$ \hspace{1cm} (28)

Thus, $L_t(Ta', Tb) \leq \delta L_t(a', b)$. Since $\delta \in [0, 1/4)$, one gets

$$\xi(a, b) < \frac{1}{\delta},$$

$$\rho(a, b) < \frac{1}{\delta},$$

$$\zeta(a, b) < \frac{1}{\delta}.$$ \hspace{1cm} (29)

Therefore, all the hypotheses of Theorem 1 are satisfied, and hence, equation (24) has a unique solution.

4.2 A Polynomial Equation of a Degree Greater or Equal to 3. The following is an application on higher degree polynomial equations.

Theorem 4. For any natural number $\beta \geq 3$ and real $|\alpha| \leq 1$, the following equation

$$a^\beta + 1 = (\beta^3 - 1)a^\beta + \beta^\alpha$$ \hspace{1cm} (30)

has a unique real solution.

Proof. It is not difficult to see that if $|\alpha| > 1$, equation (30) does not have a solution. So, let $X = [-1, 1]$ and for all $\alpha, r \in X$, let $L_t(\alpha, r) = |\alpha - r| + |\alpha - r|$ and $\xi(u, v) = 3, \rho(u, v) = 4$ and $\zeta(u, v) = \max\{u, v\} + 2$. Note that $(X, L_t)$ is a $L_t$-complete CV-TCMS. Now, let

$$Ta = \frac{a^\beta + 1}{(\beta^3 - 1)a^\beta + \beta^\alpha}.$$ \hspace{1cm} (31)
Notice that, since $\beta \geq 2$, we can deduce that $\beta^4 \geq 6$. Thus,

$$L_i(\mathcal{T}a, \mathcal{T}r) = \frac{\alpha^\beta + 1}{(\beta^4 - 1)\alpha^\beta + \beta^3} - \frac{\rho^\beta + 1}{(\beta^4 - 1)\rho^\beta + \beta^3}$$

$$+ i\frac{\alpha^\beta + 1}{(\beta^4 - 1)\alpha^\beta + \beta^3} - \frac{\rho^\beta + 1}{(\beta^4 - 1)\rho^\beta + \beta^3}$$

$$= \frac{\alpha^\beta - \rho^\beta}{((\beta^4 - 1)\alpha^\beta + \beta^3)((\beta^4 - 1)\rho^\beta + \beta^3)}$$

$$+ i\frac{\alpha^\beta - \rho^\beta}{((\beta^4 - 1)\alpha^\beta + \beta^3)((\beta^4 - 1)\rho^\beta + \beta^3)}$$

$$\leq \frac{|\alpha - \rho|}{\beta^4} + i\frac{|\alpha - \rho|}{\beta^4} \leq \frac{|\alpha - \rho|}{6} + i\frac{|\alpha - \rho|}{6}$$

$$= \frac{1}{6} L_i(\alpha, r).$$

(32)

Hence,

$$L_i(\mathcal{T}a, \mathcal{T}r) \leq \delta L_i(\alpha, r), \quad \text{where} \quad \delta = \frac{1}{6}. \quad \text{(33)}$$

Moreover, it is easy to see that for all $\alpha_0 \in \mathcal{X}$, we have

$$\alpha_n = \mathcal{T}^n \alpha_0 \leq \frac{2}{\beta^4}. \quad \text{(34)}$$

Note that all the conditions of Theorem 1 are satisfied. Thus, $\mathcal{T}$ possesses a unique fixed point in $\mathcal{X}$, and equation (30) has a unique real solution.

5. Conclusion

Finally, we would like to leave the following questions.

**Question 1.** Let $(\mathcal{X}, L_i)$ be a CV-TCMS and $\mathcal{T} : \mathcal{X} \to \mathcal{X}$. Given a function $\varsigma : \mathcal{X} \to [0,1]$. Suppose there exists $\delta \in (0,1)$ such that, for all $s, r \in \mathcal{X}$,

$$L_i(\mathcal{T}s, \mathcal{T}r) \leq \delta \varsigma(s, r)L_i(s, r). \quad \text{(35)}$$

Under what conditions does $\mathcal{T}$ have a unique fixed point in $\mathcal{X}$?

**Question 2.** Let $(\mathcal{X}, L_i)$ be a CV-TCMS, and $\mathcal{T} : \mathcal{X} \to \mathcal{X}$. Given a function $\varsigma : \mathcal{X} \to [0,1]$. Suppose there exists $\delta \in (0,1/2)$ such that, for all $s, r \in \mathcal{X}$,

$$L_i(\mathcal{T}s, \mathcal{T}r) \leq \delta \varsigma(s, r)[L_i(s, \mathcal{T}s) + L_i(r, \mathcal{T}r)]. \quad \text{(36)}$$

Under what conditions does $\mathcal{T}$ have a unique fixed point in $\mathcal{X}$?

**Data Availability**

Data sharing is not applicable to this article as no data set were generated or analyzed during the current study.

**Conflicts of Interest**

The authors declare no conflict of interest.

**Authors’ Contributions**

All the authors have equally contributed to the final manuscript.

**Acknowledgments**

The authors would like to thank Prince Sultan University for funding this work through research group Nonlinear Analysis Methods in Applied Mathematics (NAMAM) group number RG-DES-2017-01-17.
