ABSTRACT

Bergenin is an important constituent of Flueggea virosa (Euphorbiaceae), a tropical plant with several traditional uses. While there are numerous reports on the isolation and characterization of bergenin, a rapid, high-throughput, readily accessible method for the isolation and characterization of the compound locally has not been reported. Isocratic elution of ethyl acetate extract via vacuum liquid chromatography (VLC) with methanol produced a white amorphous solid (100 mg), which was successfully isolated from 250 g of the plant. On the basis of spectral data (1H, 13C NMR, COSY, HSQC and HMBC) and comparison with literature reports, the structure of this solid was shown to be bergenin, a dihydroisocoumarin derivative of glucopyranosyl gallic acid.

Key words: Flueggea virosa, bergenin, Isocoumarins, NMR, Nigeria

INTRODUCTION

Flueggea virosa (Family: Euphorbiaceae) grows wild in tropical Africa and most parts of the world. It is a woody shrub with many branches that are erect or arching; lower branches often have thorny end. It has grey or brown bark that is smooth, fissured or rough [1]. Flueggea virosa is found throughout the tropical regions of Africa and Asia where it is often found along water courses and in fallow, disturbed lands up to 2300 m above sea level [2].

Different parts of the plant are used to treat many diseases like diabetes, HIV – AIDS and related infection, arrhythmia, malaria, fever, hepatitis and epilepsy [3]. It has been used in a number of biological assays such as antiarrhythmic, antioxidant, trypanocidal and antiplasmodial [3, 4]. In Benue State of North Central Nigeria, aerial parts of the plant are used for the treatment of malaria while leaves are used as animal feed. The plant leaves are also used to check bleeding and toothache among the Tiv of North-Central Nigeria. Inhalation of smoke from the burning leaves of Flueggea virosa is believed to ease rheumatoid pain (Akpitii) [5].

The compounds 11-O-acetyl bergenin, bergenin, virosecurinine, ent-phyllanthidine, kaempferol, quercetin, gallic acid, daucosterol, β-sitosterol along with securinega alkaloids and fluagegenoids have been isolated from the twigs and leaves of Flueggea virosa [6-10]. There are several ethno-medicinal claims on the leaves of the plant here in Nigeria [11-12]. Therefore, chemical studies on this plant will be of importance in its chemotaxonomy as well as identification of compounds of potential value. Also, while there are many reports on the isolation and characterization of Bergenin from Flueggea virosa and some of these show a rapid and high-throughput method, a facile, rapid, accessible high-throughput method for the isolation and structural elucidation of bergenin from leaves of F. virosa.

MATERIALS AND METHODS

Sample collection, Pretreatment and Microwave Assisted Extraction

Leaves of F. virosa were collected around Makurdi Metropolis, Benue State Nigeria in August 2016, air-dried for three weeks and ground to powder. Powdered sample (250 g) were placed in a Winchester bottle (2.5 L) and extracted sequentially with 1 L each of n-hexane, ethyl acetate and methanol via microwave assisted extraction. For each extraction, a bottle was placed in a microwave oven, set at the defrost function (70 Kw), and irradiated for 3 minutes after which it was allowed to cool for one minute; also, pent pressure was released by partially opening the
bottle cap. This was repeated 10 times for each solvent as described by Otto [13].

**Isolation**

Ethyl acetate extract (5 g), pre-adsorbed on Celite®, was allowed to dry and loaded on to vacuum liquid chromatography column (VLC) (packed with 30 g of silica gel (TLC grade), for purification as described by Tor-Anyiin et al., [14]. After washing several with hexane (20 washes), the column was eluted with a gradient of n-hexane in ethyl acetate as mobile phase, collecting 30 fractions. Thereafter, 100% methanol (mobile phase) was utilized to collect 10 more fractions, affording a total of 40 fractions (20 mL each). The column flow rate was at about 8 mL/minute. Fractions 31 – 40, eluted isocratically with methanol gave a white solid on drying which was washed severally with n-hexane to obtain a neat solid. TLC of the white solid was performed on a pre-coated silica gel plate (silica gel GF 254, Merck®) using chloroform: methanol (9:1 v/v) solvent system as mobile phase. The plate was sprayed with 10% sulphuric acid in methanol and then heated to about 120 °C for 1 minute to visualize spots from which Rf was determined. Melting point of the isolated compound was determined based on the procedure by Philip [15].

A portion of the solid (10 mg) was dissolved in methanol (5 mL) and from this, an aliquot (2 mL) was treated with 4 drops of 10% ferric chloride solution (w/v). The formation of a bluish black colour indicated presence of a gallic tannin [16].

**Characterization of the Isolate**

Nuclear magnetic resonance experiments were carried out using a Bruker machine at 400 MHz (Proton) and 125 MHz (Carbon-13) using DMSO-d6 as solvent. Both 1D and 2D (HSQC, HMBC and COSY) spectra were acquired.

MestReNova® and Chemsketch® (ACDLABs) softwares were used in elucidating signal properties [2D NMR correlations were illustrated using the ACD labs ChemSketch (2015) software].

**RESULT AND DISCUSSION**

A white amorphous solid was obtained from the VLC of ethyl acetate crude extract of *F. virosa*. TLC of the solid gave a single dark spot (Rf = 2.3) when the plate was sprayed with 10% sulfuric acid in methanol and heated at 120 °C. This is suitable for detection of most polar compounds. The solid melted at a temperature of 237 – 240 °C. A blue black colouration obtained from FeCl3 test suggested that the white solid could be a galloyl tannin [9]. The proton NMR spectrum (summarized in Table 1) showed two phenolic-OH downfield signals at δH (9.75, 8.47) as singlets; three hydroxyl signals at δH (5.65, 5.45, 3.86), all singlets, which suggested the presence of an aromatic and an aliphatic group in the compound. Seven oxygen containing signals (at δH 3.85, 3.65, 3.44, 3.21, 4.99, 3.57, 4.02) (d, ddd and ddd) were also observed from the spectrum which corresponded to signals due to H-11, H-4, H-11, H-3, H-10b, H-2 and H-4a, respectively. These signals are similar to reports of Nguyen et al., [17] for bergenin. The positions of these protons were confirmed by analysis of its 1H-1H COSY and HSQC spectra. In addition, two singlet signals at δH 3.78 and 6.99 were assigned to a methoxy group (OCH3) and an aromatic proton (H-7), respectively, in accordance to Lin et al. [18].

13C-NMR spectrum (summarized in Table 1) showed methoxy and lactone carbon signals at δC 60.3 and 164.3 (C-6), respectively. The remaining twelve signals were characteristic of carbons from a glucosyl unit and an aromatic nucleus [18]. These data were comparable to those published for bergenin by Nguyen et al. [17] and Silva et al. [19].

The HSQC spectrum showed the following correlations between C and H atoms:

δCH: 3.57, 82.3 (CH aliphatic, C-2); 3.21, 71.2 (CH aliphatic, C-3); 3.65, 74.2 (CH aliphatic, C-4); 4.02, 80.3 (CH aliphatic, C-4a); 6.99, 110.2 (CH aromatic, C-7); 4.98, 72.6 (CH aliphatic, C-10b); 3.85 and 3.44, 61.7 (CH2 aliphatic, C-11) and 3.78, 60.3 (OCH3). The HSQC correlations confirmed that only one proton (δH 6.99, H-7) was attached to the aromatic carbon (δC 110.2, C-7). HSQC also revealed correlations typical of an aliphatic nucleus. A correlation typical of anomic
proton (δ_H 4.98, H-10b) and carbon (δ_C 72.6, C-10b) was also observed. This further suggested the presence of an aromatic and sugar nucleus [20].

It was evident from the HMBC spectrum that the aromatic proton signal at δ_H 6.99 (H-7) correlated to a carbonyl carbon at δ_C 164.3 (C-6) and two oxygenic aromatic carbons at δ_C 141.3 (C-9) and 151.9 (C-8). The aromatic proton (H-7) also correlated to a tertiary aromatic carbon at δ_C 116.6 (C-10a). Therefore, a carbonyl group could be attached at C-6a that is ortho to the carbon bearing the only aromatic proton. Furthermore, the methoxy proton signal at δ_H 3.78 correlated to an aromatic carbon at δ_C 141.3 (C-9), thus implying that the methoxy group could be attached on the aromatic ring at C-9 which was meta to C-7 but para to C-6a- bearing the benzoyl carbon (C-6, δ_C 118.6).

It was also noted from HMBC spectrum that H-10b, δ_H 4.99 (anomeric proton) correlated to one oxygenic aromatic carbon at δ_C 148.6 (C-10) and two other aromatic carbons at δ_C 116.6 (C-10a) and δ_C 118.6 (C-6a) [11]. The later (C-6a) was observed to correlate to H-4a (δ_H 4.02) which suggested that the sugar unit was C-C joined at C-10a of the aromatic ring via anomeric carbon (δ_C 72.6, C-10b) [18].

The downfield signal of H-4a (δ_H 4.02) appeared to be higher than those of other sugar protons except the anomeric proton (δ_H 4.99). This suggested that C-4a (δ_C 80.3) could be linked to C-6 (carbonyl carbon- electron withdrawing) through ethereal oxygen in a cyclic ester (lactone) formation.

Table 1: ¹H NMR and ¹³C NMR Experimental and Literature Data of Bergenin (400 MHz, DMSO-d₆, J in Hz)

| Position | Exp. Data | Nguyen et al., [17] | Silva et al., [19] |
|----------|-----------|---------------------|-------------------|
|          | ¹H (δ)    | ¹³C (δ)             | ¹H (δ)            | ¹³C (δ) |
| 2        | 3.57 (ddd; 9.7, 7.5, 2.1, 1H) | 82.3 | 3.64 | 82.0 | 3.85 | 81.9 |
| 3        | 3.21 (dd; 9.8, 8.4, 1H) | 71.2 | 3.37 | 70.8 | 3.43 | 70.7 |
| 4        | 3.65 (d, 9.0, 1H) | 74.2 | 3.68 | 74.1 | 3.68 | 74.4 |
| 4a       | 4.02 (dd; 10.5, 9.5, 1H) | 80.3 | 4.02 | 80.2 | 4.03 | 80.2 |

| 10-OH    | 9.75 (s, 1H) | - | 9.36 | - | - | - |
| 11-OH    | 3.86 (s, 1H) | - | 3.88 | - | - | - |
$^1$H and $^{13}$C chemical shifts data (Tables 1) of the white solid obtained from leaves of *Flueggea virosa* were in agreement with literature data reported by Silva *et al.*, [19] and Nguyen *et al.*, [17]. Similarly, melting point (237-240 °C) of the isolated compound was in agreement with that (238-240 °C) reported by Raj *et al.*, [21]. Based on these experimental analyses and comparison with literature reports, the white solid was identified as bergenin. Bergenin is a dihydroisocoumarin derivative of glucopyranosylgallic acid [22].

Bergenin has been isolated from several plant species including: *Ardisia crenata*, *Rodgersia ambucifolia*, *Bergenia aligulata*, *Ficus glomerata*, *Peltophorum africanum* and *Peltophorum pterocarpum* etc. It has been reported that bergenin displays several pharmacological properties such as antiplasmodial, antimicrobial, antiviral and antifungal; as well, exhibits antioxidant activity [4, 13, 21-26].

**Conclusion**

Motivated by lack of information on a facile method for isolation and purification of bergenin, a compound with high therapeutic potential, a method for isolating it from leaves of *Flueggea virosa* was sought. A rapid protocol for its isolation was established using VLC and Microwave Assisted Extraction. The extensive treatment of NMR data and isolation protocol will also contribute baseline data to the phytochemistry of *Flueggea virosa*.
