Abstract

Diabetic ulceration is a multi-factorial problem which is responsible for considerable morbidity threatening the health care system. By knowing the clinical profile and bio-burden on diabetic ulcer, it is highly beneficial for health treatment. The purpose of the present study was to evaluate the diversity of major bacterial etiology in diabetic ulcer patients. The different samples like pus, swab, and infected tissues were collected from diabetic ulcer patients aseptically and samples were transported through cold chain to the laboratory. The samples were cultured in nutrient agar, mannitol salt agar, macConkey agar and blood agar. Suspected colonies were biochemically confirmed for the isolation of *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *E.coli* and *Klebsiella* spp. In total 150 diabetic ulcer patients suffering from diabetic foot ulcers, gangrene, burn cases and accidental ulcer cases were analyzed. However, most of the patients developed mono-microbial infection; *S.aureus* was the most prevalent microbe in diabetic ulcer cases, which were positive for *nucA* gene.

**Keywords:** *S. aureus*, Diabetic foot ulcer, Etiology
INTRODUCTION

Diabetes is a major health issue that has reached alarming levels with nearly half a billion people living with diabetes worldwide. At present, 463 million adults are living with diabetes and by 2045, this will rise to 700 million1. The proportion of people with type 2 diabetes is increasing in most countries. Along with the rising prevalence of diabetes, an increase in its complications is also expected. Patients with diabetes are more susceptible to infections due to increased glucose levels and suppressed immune response as well as the neuropathy and decreased blood flow to the extremities that lead to slow-healing wounds2. Diabetic foot ulcerations and infections are one of the major medical, social, economic problem and the leading cause of morbidity and mortality, especially in the developing countries like India3. It is estimated that around 15% of diabetic patients develop foot ulcers in their life time. Diabetes accounts for more than 50% of amputation of which 85% of lower amputation in diabetes patients are preceded by foot ulcers4. The global prevalence of diabetic foot ulcers varies from 3% in Oceania to 13% in North America, with a global average of 6.4%.The annual incidence of diabetic foot ulcer (DFUs) or necrosis in diabetic patients is known to be about 2% to 5% and the lifetime risk ranges from 15% to 20%5. Diabetic foot ulcers are most commonly caused by irritated or wounded feet, nerve damage, poor circulation and hyperglycaemia. Unusual swelling, redness, irritation and stenches on one or both feet are common initial symptoms of foot ulcers6. Prevalence of diabetic foot ulcer in the clinical population of India is found to be about 2% to 5% and the lifetime risk ranges from 15% to 20%7. Diabetic foot ulcers are most commonly caused by irritated or wounded feet, nerve damage, poor circulation and hyperglycaemia. Unusual swelling, redness, irritation and stenches on one or both feet are common initial symptoms of foot ulcers8. Prevalence of diabetic foot ulcer in the clinical population of India is found to be about 2% to 5% and the lifetime risk ranges from 15% to 20%9. Tissue samples were obtained from depth of ulcers and transferred aseptically into labelled sampling vials with sterile saline and processed in the Microbiology laboratory Regional Medical Research Centre, Bhubaneswar.

MATERIALS AND METHODS

Study subjects

One hundred and fifty patients with diabetes attending general surgery ward for diabetic foot ulcer management at different tertiary care Hospital, Bhubaneswar were included during the study period from November 2019 to March 2020. Patients willing to participate in the study were enrolled. Samples were collected from patients with different grades of wounds/ulcers and gangrene after obtaining written informed consent among the age group of ≥18 years.

Data collection

Socio-demographic and anthropological data [age, marital status, literacy status, occupation, life style (sedentary/ active), familial history (parents/siblings), reasons for stress, duration and severity of disease, along with type of treatment (oral anti-diabetic/ insulin), etc. were collected from patients with diabetes using standardized questionnaires.

Sample collection

Samples were collected from patients with diabetes having ulcers, surgical sites with infection and other wounds by needle aspirate method. In case of closed wounds, the skin or mucosal surface were disinfected with 2% chlorhexidine or 70% alcohol followed by iodine solution (1-2% tincture iodine or 10% solution of povidone-iodine). Prior to specimen collection, removal of iodine with alcohol was done. In case of open wounds, debridement, was thoroughly rinsed with sterile saline prior to collection8. Tissue samples were obtained from depth of ulcers and transferred aseptically into labelled sampling vials with sterile saline and processed in the Microbiology laboratory Regional Medical Research Centre, Bhubaneswar.

Microbial analysis

Samples were streaked on nutrient agar, mannitol salt agar, macConkey Agar (MCA) and incubated aerobically for 18-24 h at 37°C. Plates with no growth or comparatively low growth will be re-incubated for another 18-48 h for isolation of bacteria that require extended incubation. Blood Agar plates were incubated in aerobic conditions. Cultural characteristics, morphological appearances of colonies on selective media, gram staining and standard biochemical tests were performed to characterize the bacteria.

DNA extraction

DNA was prepared from bacteria as described previously9. In brief, a single colony forming unit(CFU) was suspended in 20 µl of lysis buffer containing 0.25% (vol/vol) sodium dodecyl sulfate and 0.05 N NaOH. After heating for 15 min at 95°C, 180µl of high-performance liquid chromatography-grade H2O (GCC Biotech) was

[9]
added and the lysis suspension was stored at 20°C for further analysis.

**PCR analysis for *S. aureus***

PCR reaction contained 2μl of DNA which was added to 23 μl of master mix containing 0.1μl of Taq polymerase, 0.5 μl of dNTPs, 0.625 μl of primers were used for amplification of the *nucA* gene (nucA1 5’GCGATTGATGG TGATACGGTT3’ and nucA2 5’AGCCAAGCCTTGACGAACTAAAGC3’), 1.5μl of MgCl₂, 2.5μl of 10X PCR buffer and 17.15μl of water (GCC Biotech). PCR was performed using the program including initial denaturation at 95°C for 10 mins, followed by 30 cycles of annealing with an temperature of 55°C was used for *nucA gene* amplification. Final extension was carried out for 5 mins at 72°C. The PCR products were visualized using agarose gel (2%) electrophoresis. Gel images were captured using the Gel documentation system.

**RESULTS**

A total of 150 patients with diabetic ulcers were enrolled. Most of them developed diabetic foot ulcers; whereas few patients developed gangrene, some also developed ulcers after an accident or burns. Out of the total patients studied 106 (73%) people developed diabetic foot ulcers; whereas 24 (16%) patients developed gangrene due to loss of blood supplies to the extremities, 9 (6%) people suffered from ulcers accidentally and only 7 (4.6%) people developed ulcers after burns. Further 85 (71%) males and 21 (67%) females developed DFUs whereas; 7 (22%) females and 17 (14%) males developed gangrene. About 5% each of males suffered from DFUs either due to accident and/or burns (Table-1 and Fig. 1). As per the age group wise distribution with signs and symptoms of disease and sepsis patient related to diabetic foot ulcer.

| Bacterial isolates | No. of Diabetic Ulcer Patients [n =150 (%)] |
|--------------------|--------------------------------------------|
| *S. aureus*        | 78 (52)                                    |
| *S. aureus + P. aeruginosa* | 15 (10)                               |
| *S. aureus + E. coli* | 21 (14)                               |
| *P. aeruginosa*    | 19 (12.66)                                 |
| *P. aeruginosa + E. coli* | 6 (4)                                   |
| *P. aeruginosa + Klebsiella sp* | 2 (1.33)                               |
| *E. coli*          | 6 (4)                                      |
| *E. coli + Klebsiella sp* | 1 (0.66)                                |
| *Klebsiella sp*    | 2 (1.33)                                   |

Table 2. Prevalence of age group and Sepsis patient related to diabetic foot ulcer

![Fig. 1. Different types of ulcers in patients with diabetes](image)

Gangrene

Burns

DFUs
symptoms of patients, 119 (79.4%) were males and 31 (20.6%) were females. 112 (74.6%) patients in the age group ≥45-55 years and 34 (22%) in the age group ≥55-65 years developed DFUs. About 105 (70%) of patients had infection from single bacterial species; whereas 45 (30%) patients had polymicrobial infection. In this study, different age groups, duration of diabetes, types of infection, duration of infection and medication were the significant risk factors in DFUs (Table 2). The microbiological profile of samples from patients with diabetic foot ulcers showed a total number of 195 isolates were detected from 150 ulcer specimens. *S.aureus* was isolated from 114 (76%) of the samples followed by 42 (28%) *Pseudomonas aeruginosa*. *E.coli* was found 34 (22%) of the samples. The infection status of samples from patients with diabetic foot ulcers.78 (52%) of the samples were infected with *S.aureus*, 19 (12%) with *Pseudomonas aeruginosa*, 6 (4%) with *E.coli* whereas; 2 (1%) had *Klebsiella spp.* only (Table-3). It was found that the major etiological agent was *S.aureus* followed by *P.aeruginosa* and *E.coli*. *S.aureus* was one of the most important microorganism that manifests a range of clinical problems resulting from high-resistance to anti-microbial agents. PCR was performed for the confirmation of *S.aureus*. All the samples were positive for *nucA* gene which confirmed the presence of *S.aureus* in diabetic ulcer patients. (Fig. 2)

| Medication              |                                               |
| Insulin                 | 74 (49.33%)                                   |
| Oral                    | 76 (50.66%)                                   |

DISCUSSION

It was observed that *S.aureus* was the major etiological agent among one hundred fifty diabetic ulcers samples, *S.aureus* were concomitantly isolated from diabetic foot ulcer patients. Our finding is consistent with previous studies reported by Mottola et al. *S.aureus* is one of the most important micro-organisms that cause clinical problems resulting high-resistance to different antimicrobial agents. Though it is rarely found in the normal flora of humans, it is frequently isolated from patients with burns, cystic fibrosis and neutropenia. *S.aureus* is one of the most common devastating complications of diabetes mellitus and the leading cause of agonizing amputation throughout the world. These infections may be colonized by pathogenic and anti-microbial resistant bacteria,
harbouring several virulence factors that could impair its successful treatment\textsuperscript{13}. Certain socio-cultural practices in India like barefoot walking, poor hygiene habits, inadequate facilities for diabetic care, low level of education and poor socio-economic conditions often lead to foot lesions and hospitalizations\textsuperscript{14}. The present study showed 80% male ascendency followed by 20% female. However, the present study is also comparable with a multicentric study from Saudi Arabia\textsuperscript{15,16}. Direct antibiotic treatment cannot be recommended as per clinical signs or symptoms of infection as there is a very fine line between colonization of micro-organisms and problematic bio-burden and the direct antibiotic treatment efficacy remains unclear on the basis of only these two major determinants. Whereas, treatment options based upon targeting microbial population to promote healing and determining infection related complications might be a novel one\textsuperscript{17}. \textit{S.aureus} may cause severe tissue damage in diabetic patients and should never be ignored as insignificant in diabetic foot ulcers. Moreover, it should never be considered a contaminant or normal flora, and it should clearly be considered a pathogen, because it may result in sepsis and amputation\textsuperscript{18}. The numerous virulence factors and toxins secreted by \textit{S.aureus} during infection that evade host immune defences are few of the challenges in managing \textit{S.aureus} infections is an inherent resistance mechanism, referred to as intrinsic resistance. Its multiplicity of resistance mechanisms may render this microbe less amenable to control by antibiotic cycling. \textit{S.aureus} is noted for its metabolic versatility and its exceptional ability to colonize a wide variety of environments and also for its intrinsic resistance to a wide variety of antimicrobial agent\textsuperscript{19}.

There are many studies that suggest that apart from clinical factors, the socio-demographic variables play an important role in diabetic foot ulceration. It was reported by DeBerardis et al (2005) that the prevalence of diabetic foot complications was higher in older patients, those with limited formal education and a low socio-demographic status\textsuperscript{20}. Our results couldn't substantiate the claim mentioned in the above study. One ninety five micro-organisms were isolated from one fifty clinical samples of diabetic foot ulcers, which showed multiple bacterial infections that represent an average of 1.3 organisms per ulcer which is slightly lower than other studies\textsuperscript{21,22}, and showed an average of 1.52 organisms per ulcer. Diabetic foot infections are usually polymicrobial in nature and this has been well documented in the literature. \textit{S.aureus} was the most common isolate observed in diabetic foot ulcers that was in accordance with findings of previous studies\textsuperscript{23,24}. The emergence of \textit{S.aureus} in the DFUs caused severe wound infection and worsened of the wound\textsuperscript{25}. However, the bacterial diversity and prevalence of specific bacteria vary greatly from studies to studies. Identification of diabetes with DFUs and its associated factors are the key to reduce further complications and to have baseline information to initiate appropriate interventions.

**CONCLUSION**

The present study reports that \textit{S.aureus} was the major etiological agent with socio-demographic and clinical profile of patients with diabetic ulcer. There was a predominance of monomicrobial growth with gram-positive organisms. Healthcare should be made more accessible to facilitate early diagnosis of DFU and its complications to minimize the rate of amputations. This type of study should be continued for a longer period both in coastal and tribal areas of Odisha.
