PHASE TRANSITION IN THE CONNES-MARCOLLI GL$_2$-SYSTEM

MARCELO LACA$^1$, NADIA S. LARSEN$^2$, AND SERGEY NESHVEYEV$^2$

ABSTRACT. We develop a general framework for analyzing KMS-states on C$^*$-algebras arising from actions of Hecke pairs. We then specialize to the system recently introduced by Connes and Marcolli and classify its KMS-states for inverse temperatures $\beta \neq 0,1$. In particular, we show that for each $\beta \in (1,2]$ there exists a unique KMS$_\beta$-state.

INTRODUCTION

More than ten years ago Bost and Connes [3] constructed a C$^*$-dynamical system with the Galois group $G(\mathbb{Q}_{ab}/\mathbb{Q})$ as symmetry group and with phase transition related to properties of zeta and L-functions. Since then there have been numerous, and only partially successful, attempts to generalize the Bost-Connes system to arbitrary number fields, see [5, Section 1.4] for a survey. As was later emphasized by Connes, the BC-system has yet another remarkable property: there exists a dense $\mathbb{Q}$-subalgebra such that the maximal abelian extension $\mathbb{Q}_{ab}$ of $\mathbb{Q}$ arises as the set of values of a ground state of the system on it. If one puts this property as a requirement for an arbitrary number field, one recognizes that the problem of finding the right analogue of the BC-system is related to Hilbert’s 12th problem on explicit class field theory. Since the only case (in addition to $\mathbb{Q}$) for which Hilbert’s problem is completely solved is that of imaginary quadratic fields, these fields should be the first to investigate. This has been done in recent papers of Connes, Marcolli and Ramachandran [5,6,7,8]. Connes and Marcolli [5,6] constructed a GL$_2$-system, an analogue of the BC-system with $\mathbb{Q}^*$ replaced by GL$_2(\mathbb{Q})$. Its specialization to a subsystem compatible with complex multiplication in a given imaginary quadratic field gives the right analogue of the BC-system for such a field [7,8]. Later Ha and Paugam [12], inspired by constructions of Connes and Marcolli, proposed an analogue of the BC-system for an arbitrary number field.

Connes and Marcolli classified KMS-states of the GL$_2$-system for inverse temperatures $\beta \notin (1,2]$. It is the primary goal of the present paper to elucidate what happens in the critical region $(1,2]$. Along the way we develop some general tools for analyzing systems of the type introduced by Connes and Marcolli, which can be thought of as crossed products of abelian algebras by Hecke algebras.

Our approach to the problem is along the lines of that of the first author in the case of the BC-system [15]. Namely, in Proposition 3.2 we show that KMS-states correspond to states on the diagonal subalgebra which are scaled by the action of GL$^+_2(\mathbb{Q})$, or rather by the Hecke operators. As our first application we recover in Theorem 3.7 the results of Connes and Marcolli. We then prove our main result, Theorem 4.1, the uniqueness of a KMS$_\beta$-state for each $\beta \in (1,2]$. The strategy is similar to that of the third author in the BC-case [18]. Namely, we prove the uniqueness and ergodicity, under the action of GL$^+_2(\mathbb{Q})$, of the measure defining a symmetric KMS$_\beta$-state by analyzing an explicit formula for the projection onto the space of Mat$^+_2(\mathbb{Z})$-invariant functions, see Lemma 4.4 and Corollary 4.7, and then derive from this the main uniqueness result. There are two

1) Supported by the Natural Sciences and Engineering Research Council of Canada.
2) Supported by the Research Council of Norway.
main complications compared to the BC-case. The first is that instead of semigroup actions we now have to deal with representations of Hecke algebras. The second is the presence in the system of a continuous component corresponding to the infinite place. As a result, the critical step now is to prove the uniqueness of a symmetric, that is, $\text{GL}_2(\mathbb{Z})$-invariant, KMS-β-state, while in the BC-case the analogous statement is almost obvious. To show this uniqueness we use a deep result of Clozel, Oh and Ullmo \cite{ALO} on equidistribution of Hecke points. We point out that, as opposed to the BC-case, there are many symmetric states for $\beta > 2$, which can be easily seen from Theorem \ref{thm:clozel} below.

1. PROPER ACTIONS AND GROUPOID $C^*$-ALGEBRAS

Let $G$ be a countable group acting on a locally compact second countable space $X$. The reduced crossed product $C_0(X) \rtimes_r G$ is the reduced $C^*$-algebra of the transformation groupoid $G \times X$ with unit space $X$, source and range maps $(g, x) \mapsto x$ and $(g, x) \mapsto gx$, respectively, and the product

$$(g, hx)(h, x) = (gh, x).$$

If the restriction of the action to a subgroup $\Gamma$ of $G$ is free and proper, we can introduce a new groupoid $\Gamma \backslash G \times \Gamma X$ by taking the quotient of $G \times X$ by the action of $\Gamma \times \Gamma$ defined by

$$(\gamma_1, \gamma_2)(g, x) = (\gamma_1 g \gamma_2^{-1}, \gamma_2 x).$$

Thus the unit space of $\Gamma \backslash G \times \Gamma X$ is $\Gamma \backslash X$, and the product is induced from that on $G \times X$. This groupoid is Morita equivalent in the sense of \cite{Laca-Neshveyev} to the transformation groupoid $G \times X$. Although we will not need this result, let us briefly recall the argument. By definition of Morita equivalence first of all we have to find a space $Z$ with commuting actions of our groupoids. We take $Z = G \times \Gamma X$, the quotient of $G \times X$ by the action of $\Gamma$ given by $\gamma(g, x) = (g \gamma^{-1}, \gamma x)$. The left and right actions of the groupoid $G \times X$ on itself induce a left action of $G \times X$ and a right action of $\Gamma \backslash G \times \Gamma X$ on $Z$. The map $Z \to \Gamma \backslash X$, $\Gamma(g, x) \mapsto \Gamma x$, induces a homeomorphism between the quotient of $Z$ by the action of $G \times X$ and the unit space $\Gamma \backslash X$ of the groupoid $\Gamma \backslash G \times \Gamma X$. Similarly, the map $Z \to X$, $\Gamma(g, x) \mapsto gx$, induces a homeomorphism between the quotient of $Z$ by $\Gamma \backslash G \times \Gamma X$ and $X$. Thus the groupoids are indeed Morita equivalent. Recall then that by \cite{Laca-Neshveyev} Theorem 2.8 the corresponding reduced $C^*$-algebras are Morita equivalent.

If the action of $\Gamma$ is proper but not free, the quotient space $\Gamma \backslash G \times \Gamma X$ is no longer a groupoid, since the composition of classes using representatives will in general depend on the choice of representatives. As was observed in \cite{ALO} and \cite{Laca-Neshveyev}, nevertheless, the same formula for convolution of two functions as in the groupoid case gives us a well-defined algebra, and by completion we get a $C^*$-algebra. In more detail, consider the space $C_c(\Gamma \backslash G \times \Gamma X)$ of continuous compactly supported functions on $\Gamma \backslash G \times \Gamma X$. We consider its elements as $(\Gamma \times \Gamma)$-invariant functions on $G \times X$, and define a convolution of two such functions by

$$(f_1 \ast f_2)(g, x) = \sum_{h \in \Gamma \backslash G} f_1(gh^{-1}, hx)f_2(h, x).$$

To see that the convolution is well-defined, assume the support of $f_1$ is contained in $(\Gamma \times \Gamma)(\{g_i\} \times U_i)$, where $g_i \in G$ and $U_i$ is a compact subset of $X$. Let $\{\gamma_1, \ldots, \gamma_n\}$ be the set of all elements $\gamma \in \Gamma$ such that $\gamma g_2 U_2 \cap U_1 \neq \emptyset$. Note that this set is finite since the action of $\Gamma$ is assumed to be proper. If $f_2(h, x) \neq 0$ then there exists $\gamma \in \Gamma$ such that $h \gamma^{-1} \in \Gamma g_2$ and $\gamma x \in U_2$. Since the number of $\gamma$'s such that $\gamma x \in U_2$ is finite, we already see that the sum above is finite. If furthermore $f_1(gh^{-1}, hx) \neq 0$ then replacing $h$ by another representative of the right coset $\Gamma h$ we may assume that $gh^{-1} \in \Gamma g_i$ and $hx \in U_1$. Then if $h \gamma^{-1} = \tilde{\gamma} g_2$ with $\tilde{\gamma} \in \Gamma$, we get $hx = \tilde{\gamma} g_2 \gamma x \in \gamma g_2 U_2$. Hence $\tilde{\gamma} = \gamma_i$ for some $i$, and therefore $g \in \Gamma g_i h = \Gamma g_1 g_i g_2 \gamma_i$. Thus the support of $f_1 \ast f_2$ is contained in the union of the sets $(\Gamma \times \Gamma)(\{g_i \gamma_i g_2\} \times U_2)$, so $f_1 \ast f_2 \in C_c(\Gamma \backslash G \times \Gamma X)$ and the latter space becomes an algebra. It is not difficult to check that the convolution is associative.
Define also an involution on $C_c(\Gamma \backslash G \times \Gamma X)$ by

$$f^*(g, x) = f((g, x)^{-1}) = f(g^{-1}, gx).$$

(1.3)

If the support of $f$ is contained in $(\Gamma \times \Gamma)(\{g_0\} \times U)$ for $g_0 \in G$ and compact $U \subset X$, then the support of $f^*$ is contained in

$$(\Gamma \times \Gamma)(\{g_0\} \times U)^{-1} = (\Gamma \times \Gamma)(\{g_0\} \times U) = (\Gamma \times \Gamma)(\{g_0^{-1}\} \times g_0U),$$

so indeed $f^* \in C_c(\Gamma \backslash G \times \Gamma X)$.

For each $x \in X$ we define a *-representation $\pi_x : C_c(\Gamma \backslash G \times \Gamma X) \to B(\ell^2(\Gamma \backslash G))$ by

$$\pi_x(f)\delta_{\Gamma y} = \sum_{g \in \Gamma \backslash G} f(gh^{-1}, hx)\delta_{\Gamma y},$$

(1.4)

where $\delta_{\Gamma y}$ denotes the characteristic function of the coset $\Gamma y$. It is standard to show that the operators $\pi_x(f)$ are bounded, but we include a proof for the reader’s convenience.

**Lemma 1.1.** For each $f \in C_c(\Gamma \backslash G \times \Gamma X)$ the operators $\pi_x(f)$, $x \in X$, are uniformly bounded.

**Proof.** For $\xi_1, \xi_2 \in \ell^2(\Gamma \backslash G)$ we have

$$|\langle \pi_x(f)\xi_1, \xi_2 \rangle| \leq \sum_{g, h \in \Gamma \backslash G} |f(gh^{-1}, hx)||\xi_1(h)||\xi_2(g)|$$

$$\leq \left( \sum_{g, h \in \Gamma \backslash G} |f(gh^{-1}, hx)||\xi_1(h)|^2 \right)^{1/2} \left( \sum_{g, h \in \Gamma \backslash G} |f(gh^{-1}, hx)||\xi_2(g)|^2 \right)^{1/2} .$$

Thus if we denote by $\|f\|_I$ the quantity

$$\max \left\{ \sup_{x \in X} \sum_{g \in \Gamma \backslash G} |f(gh^{-1}, hx)|, \sup_{x \in X} \sum_{g \in \Gamma \backslash G} |f(gh^{-1}, hx)| \right\} ,$$

we get $\|\pi_x(f)\| \leq \|f\|_I$ for any $x \in X$, so it suffices to show that $\|f\|_I$ is finite. Replacing $x$ by $h^{-1}x$ and $g$ by $gh$ in the first supremum above, we see that this supremum equals

$$\|f\|_{I,s} := \sup_{x \in X} \sum_{g \in \Gamma \backslash G} |f(g, x)| .$$

Observe next that $f(gh^{-1}, hx) = f^*(hg^{-1}, gx)$, so that the second supremum is equal to $\|f^*\|_{I,s}$. Therefore $\|f\|_I = \max\{\|f\|_{I,s}, \|f^*\|_{I,s}\}$. It remains to show that $\|f\|_{I,s}$ is finite for any $f \in C_c(\Gamma \backslash G \times \Gamma X)$.

Assume the support of $f$ is contained in $(\Gamma \times \Gamma)(\{g_0\} \times U)$ for some $g_0 \in G$ and compact $U \subset X$. Since the action of $\Gamma$ is proper, there exists $n \in \mathbb{N}$ such that the sets $\gamma U$, $i = 1, \ldots, n+1$, have trivial intersection for any different $\gamma_1, \ldots, \gamma_{n+1} \in \Gamma$. Now if $f(g, x) \neq 0$ for some $g$ and $x$, there exists $\gamma \in \Gamma$ such that $\gamma g^{-1} \in \Gamma g_0$ and $\gamma x \in U$. Since the number of $\gamma$’s such that $\gamma x \in U$ is at most $n$, we see that for each $x \in X$ the sum in the definition of $\|f\|_{I,s}$ has at most $n$ nonzero summands. Hence $\|f\|_{I,s}$ is finite, and the proof of the lemma is complete. \qed

We denote by $C^*_r(\Gamma \backslash G \times \Gamma X)$ the completion of $C_c(\Gamma \backslash G \times \Gamma X)$ in the norm defined by the representation $\oplus_{x \in X} \pi_x$, that is,

$$\|f\| = \sup_{x \in X} \|\pi_x(f)\| .$$

Denoting by $U_g$ the unitary operator on $\ell^2(\Gamma \backslash G)$ such that $U_g\delta_{\Gamma y} = \delta_{\Gamma yg^{-1}}$, we get $U_g\pi_x(f)U_g^* = \pi_{gx}(f)$. Hence $\|\pi_x(f)\| = \|\pi_{gx}(f)\|$ and so the supremum above is actually over $G \backslash X$.

Using the embedding $X \hookrightarrow G \times X$, $x \mapsto (e, x)$, we may consider $\Gamma \backslash X$ as an open subset of $\Gamma \backslash G \times \Gamma X$, and then the algebra $C_0(\Gamma \backslash X)$ as a subalgebra of $C^*_r(\Gamma \backslash G \times \Gamma X)$. More generally, any bounded continuous function on $\Gamma \backslash X$ defines a multiplier of $C^*_r(\Gamma \backslash G \times \Gamma X)$. 

Lemma 1.2. There exists a conditional expectation $E: C^*_r(\Gamma \backslash G \times \Gamma) \to C_0(\Gamma \backslash X)$ such that

$$E(f)(x) = f(e, x) \quad \text{for } f \in C_c(\Gamma \backslash G \times \Gamma).$$

Proof. For each $x \in X$ define a state $\omega_x$ on $C^*_r(\Gamma \backslash G \times \Gamma)$ by

$$\omega_x(a) = (\pi_x(a)\delta_{\Gamma}, \delta_{\Gamma}).$$

Then the function $E(a)$ on $X$ defined by $E(a)(x) = \omega_x(a)$ is bounded by $\|a\|$. Since $E(f)(x) = f(e, x)$ for $f \in C_c(\Gamma \backslash G \times \Gamma)$, we conclude that $E(a) \in C_0(\Gamma \backslash X)$ for every $a \in C^*_r(\Gamma \backslash G \times \Gamma)$. Thus $E$ is the required conditional expectation. \qed

Let $Y \subset X$ be a $\Gamma$-invariant clopen subset. Then, as we already observed, the characteristic function $\mathbb{1}_{\Gamma \backslash Y}$ of the set $\Gamma \backslash Y$ is an element of the multiplier algebra of $C^*_r(\Gamma \backslash G \times \Gamma)$. Denote by $\Gamma \backslash G \boxtimes_\Gamma Y$ the quotient of the space

$$\{(g, x) \mid g \in G, x \in Y, gx \in Y\}$$

by the action of $\Gamma \times \Gamma$ defined as in [11]. Then

$$\mathbb{1}_{\Gamma \backslash Y} C_c(\Gamma \backslash G \times \Gamma) \mathbb{1}_{\Gamma \backslash Y} = C_c(\Gamma \backslash G \boxtimes_\Gamma Y).$$

Therefore the algebra $\mathbb{1}_{\Gamma \backslash Y} C^*_r(\Gamma \backslash G \times \Gamma) \mathbb{1}_{\Gamma \backslash Y}$, which we shall denote by $C^*_r(\Gamma \backslash G \boxtimes_\Gamma Y)$, is a completion of the algebra of compactly supported functions on $\Gamma \backslash G \boxtimes_\Gamma Y$ with convolution product given by

$$(f_1 \ast f_2)(g, y) = \sum_{h \in \Gamma \backslash G; \; hy \in Y} f_1(gh^{-1}, hy)f_2(h, y),$$

and involution

$$f^*(g, y) = \overline{f(g^{-1}, gy)}.$$ 

Note that $\pi_x(\mathbb{1}_{\Gamma \backslash Y})$ is the projection onto the subspace $\ell^2(\Gamma \backslash G_x)$ of $\ell^2(\Gamma \backslash G)$, where the subset $G_x$ of $G$ is defined by

$$G_x = \{g \in G \mid gx \in Y\},$$

and then

$$\pi_x(f)\delta_{\Gamma h} = \sum_{g \in \Gamma \backslash G_x} f(gh^{-1}, hx)\delta_{\Gamma g}$$

for $h \in G_x$ and $f \in C_c(\Gamma \backslash G \boxtimes_\Gamma Y)$. In particular, $\pi_x(f) = 0$ if $x \notin GY$. As we already remarked, the representations $\pi_x$ and $\pi_{gx}$ are unitarily equivalent for any $g \in G$. Thus we may conclude that $C^*_r(\Gamma \backslash G \boxtimes_\Gamma Y)$ is precisely the completion of $C_c(\Gamma \backslash G \boxtimes_\Gamma Y)$ in the norm

$$\|f\| = \sup_{g \in Y} \|\pi_g(f)\|.$$ 

This is how the algebra $C^*_r(\Gamma \backslash G \boxtimes_\Gamma Y)$ was defined (in a particular case) in [5, Proposition 1.23].

Returning to the algebra $C^*_r(\Gamma \backslash G \times \Gamma)$, our next goal is to show that under an extra assumption its multiplier algebra contains other interesting elements in addition to the $\Gamma$-invariant functions on $X$.

Recall that $(G, \Gamma)$ is called a Hecke pair if $\Gamma$ and $g\Gamma g^{-1}$ are commensurable for any $g \in G$, that is, $\Gamma \cap g\Gamma g^{-1}$ is a subgroup of $\Gamma$ of finite index. Equivalently, every double coset of $\Gamma$ contains finitely many right (and left) cosets of $\Gamma$, so that

$$R_{\Gamma}(g) := |\Gamma \backslash \Gamma g\Gamma| < \infty \text{ for any } g \in G.$$ 

Then the space $\mathcal{H}(G, \Gamma)$ of finitely supported functions on $\Gamma \backslash G / \Gamma$ is a *-algebra with product

$$(f_1 \ast f_2)(g) = \sum_{h \in \Gamma \backslash G} f_1(gh^{-1})f_2(h).$$
and involution $f^*(g) = \overline{f(g^{-1})}$, see e.g. [13]. This algebra is represented on $\ell^2(\Gamma \backslash G)$ by

$$f \delta_{\Gamma h} = \sum_{g \in \Gamma \backslash G} f(gh^{-1}) \delta_{\Gamma g},$$

see [3]. The corresponding completion is called the reduced Hecke C*-algebra of $(G, \Gamma)$ and denoted by $C_\text{r}(G, \Gamma)$. We shall denote by $[g]$ the characteristic function of the double coset $\Gamma g \Gamma$ considered as an element of the Hecke algebra.

We may consider elements of $\mathcal{H}(G, \Gamma)$ as continuous functions on $\Gamma \backslash G \times \Gamma X$. Although these functions are not compactly supported in general, the formulas defining the *-algebra structure and the regular representation of $\mathcal{H}(G, \Gamma)$ coincide with (1.2)–(1.4). Furthermore, the convolution of an element of $\mathcal{H}(G, \Gamma)$ with a compactly supported function on $\Gamma \backslash G \times \Gamma X$ gives a compactly supported function. Indeed, if $f = [g_1]$ and the support of $f_2 \in C_c(\Gamma \backslash G \times \Gamma X)$ is contained in $(\Gamma \times \Gamma)(\{g_2\} \times U)$ for a compact $U \subset X$, then the support of $f_1 \ast f_2$ is contained in $(\Gamma \times \Gamma)(g_2 \Gamma g_2 \times U)$. Since $\Gamma g_1 \Gamma g_2$ is finite, we see that $f_1 \ast f_2$ is compactly supported on $\Gamma \backslash G \times X$. We may therefore conclude the following.

**Lemma 1.3.** If $(G, \Gamma)$ is a Hecke pair, then the reduced Hecke C*-algebra $C_\text{r}(G, \Gamma)$ is contained in the multiplier algebra of the C*-algebra $C_\text{r}(\Gamma \backslash G \times \Gamma X)$.

It is then tempting to think of $C_\text{r}(\Gamma \backslash G \times \Gamma X)$ as a crossed product of $C_\text{r}(\Gamma \backslash X)$ by an action of the Hecke pair $(G, \Gamma)$. This point of view has been formalized by Tzanev [21] who introduced a notion of a crossed product of an algebra by an action of a Hecke pair.

**Remark 1.4.** We defined $C_\text{r}(\Gamma \backslash G \times \Gamma X)$ assuming that the action of $\Gamma$ on $X$ is proper. It is however easy to see that the construction makes sense under the following weaker assumptions: $\Gamma \backslash G \times \Gamma X$ is Hausdorff, and if for a compact set $K \subset X$ we put $\Gamma K = \{\gamma \in \Gamma \mid \gamma K \cap K \neq \emptyset\}$ then the set $\Gamma \backslash G \Gamma K$ is finite for any $g \in G$. Note that the second assumption is automatically satisfied when $(G, \Gamma)$ is a Hecke pair.

2. Dynamics and KMS-states

Assume as above that we have an action of $G$ on $X$ such that the action of $\Gamma \subset G$ is proper, and $Y \subset X$ is a $\Gamma$-invariant clopen set. Assume now that we are given a homomorphism

$$N: G \to \mathbb{R}^*_+ = (0, +\infty)$$

such that $\Gamma$ is contained in the kernel of $N$. Then we define a one-parameter group of automorphisms of $C_\text{r}(\Gamma \backslash G \times \Gamma X)$ by

$$\sigma_t(f)(g, x) = N(g)^{it} f(g, x) \quad \text{for} \quad f \in C_c(\Gamma \backslash G \times \Gamma X).$$

More precisely, if we denote by $\tilde{N}$ the selfadjoint operator on $\ell^2(\Gamma \backslash G)$ defined by

$$\tilde{N} \delta_{hg} = N(g) \delta_{\Gamma g},$$

then the dynamics $\sigma_t$ is spatially implemented by the unitary operator $\oplus_{x \in X} \tilde{N}^{it}$ on $\oplus_{x \in X} \ell^2(\Gamma \backslash G)$. In other words,

$$\pi_x(\sigma_t(a)) = \tilde{N}^{it} \pi_x(a) \tilde{N}^{-it} \quad \text{for all} \quad x \in X.$$

Recall, see e.g. [14], that a semifinite $\sigma$-invariant weight $\varphi$ is called a $\sigma$-KMS$_\beta$-weight if

$$\varphi(aa^*) = \varphi(\sigma_{i\beta/2}(a)\sigma_{i\beta/2}(a))$$

for any $\sigma$-analytic element $a$. The following result will be the basis of our analysis of KMS-weights.
Proposition 2.1. Assume the action of $G$ on $X$ is free, so that in particular $\Gamma \setminus G \bowtie Y$ is a genuine groupoid. Then for any $\beta \in \mathbb{R}$ there exists a one-to-one correspondence between $\sigma$-KMS$_{\beta}$ weights $\varphi$ on $C_r^*(\Gamma \setminus G \bowtie Y)$ with domain of definition containing $C_\sigma(\Gamma \setminus Y)$ andRadon measures $\mu$ on $Y$ such that
$$\mu(gZ) = N(g)^{-\beta} \mu(Z)$$
(2.1)
for every $g \in G$ and every compact subset $Z \subset Y$ such that $gZ \subset Y$. Namely, such a measure $\mu$ is $\Gamma$-invariant, so it determines a measure $\nu$ on $\Gamma \setminus Y$ such that
$$\int_Y f(y) \, d\mu(y) = \int_{\Gamma \setminus Y} \left( \sum_{y \in p^{-1}(\{t\})} f(y) \right) \, d\nu(t) \quad \text{for} \quad f \in C_\sigma(\Gamma \setminus Y),$$
(2.2)
where $p: Y \to \Gamma \setminus Y$ is the quotient map, and the associated weight $\varphi$ is given by
$$\varphi(a) = \int_{\Gamma \setminus Y} E(a)(x) \, d\nu(x),$$
where $E$ is the conditional expectation defined in Lemma 1.2.

Proof. For $\Gamma = \{e\}$ the result is well-known, see e.g. [19] Proposition II.5.4. For arbitrary $\Gamma$ the result can be deduced from the fact that the $C^*$-algebra $C_r^*(\Gamma \setminus G \bowtie Y)$ is Morita equivalent to the $C^*$-algebra $1_Y (C_0(X) \rtimes G) 1_Y$ and general results on KMS-weights on Morita equivalent algebras, see [16] Theorem 3.2. However, a more elementary way is to argue as follows.

Since the action of $\Gamma$ on $Y$ is free, the quotient space $\Gamma \setminus G \bowtie Y$ is an etale groupoid. In fact it is an etale equivalence relation on $\Gamma \setminus Y$, or an $\Gamma$-discrete principal groupoid in the terminology of [19]. To see this we have to check that the isotropy group of every point in $\Gamma \setminus Y$ is trivial, that is, if $g \in G$ is such that $gy \in Y$ and $p(gy) = p(y)$ for some $y \in Y$ then $(g, y)$ belongs to the $(\Gamma \times \Gamma)$-orbit of $(e, y)$.

But if $p(gy) = p(y)$, there exists $\gamma \in \Gamma$ such that $\gamma g y = y$. Then $\gamma g = e$, since the action of $G$ is free, and therefore $(g, y) = (\gamma^{-1}, e)(e, y)$.

It is then standard to show using [19] Proposition II.5.4 that $\sigma$-KMS$_{\beta}$ weights (with domain of definition containing $C_\sigma(\Gamma \setminus Y)$) on the $C^*$-algebra $C_r^*(\Gamma \setminus G \bowtie Y)$ of the etale equivalence relation are in one-to-one correspondence with measures $\nu$ on $\Gamma \setminus Y$ with Radon-Nikodym cocycle $(p(y), p(gy)) \mapsto N(g)^{\beta}$. The latter means the following, see [19] Definition I.3.4. Assume $Y_0$ is an open subset of $Y$ such that the map $p: Y \to \Gamma \setminus Y$ is injective on $Y_0$, and $g \in G$ is such that $gY_0 \subset Y$. Define an injective map $\tilde{g}: p(Y_0) \to p(gY_0)$ by $\tilde{g}p(y) = p(gy)$ for $y \in Y_0$, and let $\tilde{g}_\nu$ be the push-forward of the measure $\nu$ under the map $\tilde{g}$, that is, $\tilde{g}_\nu(Z) = \nu(\tilde{g}^{-1}(Z))$ for $Z \subset p(gY_0)$. Then
$$\frac{d\tilde{g}_\nu}{d\nu} = N(g)^{\beta} \quad \text{on} \quad p(gY_0).$$

If we denote by $\mu$ the $\Gamma$-invariant measure on $Y$ corresponding to $\nu$ via (2.2), then to say that the Radon-Nikodym cocycle of $\nu$ is $(p(y), p(gy)) \mapsto N(g)^{\beta}$ is the same as saying that $\mu$ satisfies the scaling condition (2.1).

It will be convenient to extend the measure $\mu$ to the set $G Y$.

Lemma 2.2. If $\mu$ is a measure on $Y$ as in Proposition 2.1 then it extends uniquely to a Radon measure on $G Y \subset X$ satisfying (2.1) for $Z \subset G Y$ and $g \in G$.

Proof. A more general result on extensions of KMS-weights is proved in [16], but the present particular case has the following elementary proof. Choose Borel subsets $Y_i \subset Y$ and elements $g_i \in G$ such that $G Y$ is the disjoint union of the sets $g_i^{-1}Y_i$. There is only one choice for a measure extending $\mu$ and satisfying (2.1) on $G Y$, namely, for a Borel subset $Z \subset G Y$ let
$$\mu(Z) = \sum_i N(g_i)^{\beta} \mu(g_i Z \cap Y_i).$$
To show that \( \mu(Z) \) is independent of any choices and that the extension satisfies (2.1), assume \( GY \)

\[
\sum_i N(g_i)^\beta \mu(g_i gZ \cap Y_i) = \sum_i N(g_i)^\beta \sum_j \mu(g_i gZ \cap Y_i \cap g_i g h_j^{-1} Z_j) = \sum_i N(g_i)^\beta \sum_j N(g_i g h_j^{-1})^{-\beta} \mu(h_j Z \cap h_j g^{-1} h_j^{-1} Y_i \cap Z_j) = N(g)^{-\beta} \sum_j N(h_j)^\beta \sum_i \mu(h_j Z \cap h_j g^{-1} h_j^{-1} Y_i \cap Z_j) = N(g)^{-\beta} \sum_j N(h_j)^\beta \mu(h_j Z \cap Z_j).
\]

Taking \( g = e \) we see that the extension of \( \mu \) to \( GY \) is well-defined. But then for arbitrary \( g \) the above identity reads as \( \mu(gZ) = N(g)^{-\beta} \mu(Z) \).

**Remark 2.3.** In the notation of Proposition 2.1 choose a \( \mu \)-measurable subset \( U \) of \( Y \) such that \( p: Y \to \Gamma \setminus Y \) is injective on \( U \) and \( p(U) = \Gamma \setminus Y \). Then the map \( p \) induces an isomorphism between the restriction \( R_{G,U} \) of the \( G \)-orbit equivalence relation on \( X \) to \( U \) and the principal groupoid \( \Gamma \setminus G \wr E_Y \). Hence \( \pi_p(C^*_r(\Gamma \setminus G \wr E_Y))' \) is isomorphic to the von Neumann algebra \( W^*(R_{G,U}) \) of \( (R_{G,U}, \mu) \), see [11]. Extend the measure \( \mu \) to a \( G \)-quasi-invariant measure on \( GY \), which we still denote by \( \mu \). Then \( W^*(R_{G,U}) \) is the reduction of the von Neumann algebra of the \( G \)-orbit equivalence relation on \( (GY, \mu) \) by the projection \( 1_U \). Therefore

\[
\pi_p(C^*_r(\Gamma \setminus G \wr E_Y))' \cong 1_U(L^\infty(GY, \mu) \times G)1_U.
\]

In some cases an argument similar to the proof of Lemma 2.2 allows us to describe all measures satisfying (2.1).

**Lemma 2.4.** Let \( Y_0 \) be a \( \Gamma \)-invariant Borel subset of \( Y \) such that

(i) if \( gY_0 \cap Y_0 \neq \emptyset \) for some \( g \in G \) then \( g \in \Gamma \);

(ii) for any \( y \in Y \) there exists \( g \in G \) such that \( gy \in Y_0 \).

Then any \( \Gamma \)-invariant Borel measure on \( Y_0 \) extends uniquely to a Borel measure on \( Y \) satisfying (2.1).

**Proof.** Let \( \mu_0 \) be a \( \Gamma \)-invariant measure on \( Y_0 \). Since the assumptions imply that \( Y \) is a disjoint union of translates of \( Y_0 \) by representatives of the right cosets of \( \Gamma \), that is, \( Y = \bigsqcup_{h \in \Gamma \setminus G} (h^{-1}Y_0 \cap Y) \), there is only one choice for a measure \( \mu \) extending \( \mu_0 \) and satisfying (2.1), namely,

\[
\mu(Z) = \sum_{h \in \Gamma \setminus G} N(h)^\beta \mu_0(hZ \cap Y_0).
\]

Since \( \mu_0 \) is \( \Gamma \)-invariant, \( \mu(Z) \) is independent of the choice of representatives, so all we need to check is that (2.1) holds. Let \( g \in G \). Then

\[
\mu(gZ) = \sum_{h \in \Gamma \setminus G} N(h)^\beta \mu_0(hgZ \cap Y_0) = N(g)^{-\beta} \sum_{h \in \Gamma \setminus G} N(hg)^\beta \mu_0(hgZ \cap Y_0) = N(g)^{-\beta} \mu(Z),
\]

and the proof is complete. \( \square \)

Although the condition for a measure \( \nu \) on \( \Gamma \setminus Y \) to define a KMS-weight is easier to formulate in terms of the corresponding \( \Gamma \)-invariant measure on \( Y \), it will also be important to work directly with \( \nu \). For this we introduce the following operators on functions on \( \Gamma \setminus X \). We shall often consider functions on \( \Gamma \setminus X \) as \( \Gamma \)-invariant functions on \( X \).
Definition 2.5. Let $G$ act on a set $X$ and suppose $(G, \Gamma)$ is a Hecke pair. The Hecke operator associated to $g \in G$ is the operator $T_g$ on $\Gamma$-invariant functions on $X$ defined by

$$(T_g f)(x) = \frac{1}{R_\Gamma(g)} \sum_{h \in \Gamma \backslash \Gamma g \Gamma} f(hx).$$

Clearly $T_g f$ is again $\Gamma$-invariant. It is not difficult to check that the map $[g^{-1}] \to R_\Gamma(g)T_g$ is a representation of the Hecke algebra $H(G, \Gamma)$ on the space of $\Gamma$-invariant functions (notice that for $X = G$ this is exactly the way we defined the regular representation of $H(G, \Gamma)$, so by decomposing an arbitrary $X$ into $G$-orbits one can obtain the general case without any computations).

The following three lemmas will be our main computational tools.

Lemma 2.6. Suppose $\mu$ is as in Proposition 2.4 and $\nu$ is the measure on $\Gamma \backslash Y$ determined by (2.2).

Assume further that $Y = X$, the action of $G$ on $X$ is free and that $(G, \Gamma)$ is a Hecke pair with modular function $\Delta_\Gamma(g) := R_\Gamma(g^{-1})/R_\Gamma(g)$. Then for any positive measurable function $f$ on $\Gamma \backslash X$ and $g \in G$ we have

$$\int_{\Gamma \backslash X} T_g f d\nu = \Delta_\Gamma(g) N(g)^{\beta} \int_{\Gamma \backslash X} f d\nu.$$ 

Proof. Fix a point $x \in X$. We claim that there exists a neighbourhood $U$ of $x$ such that the sets $hU$ are disjoint for different $h \in \Gamma g^{-1} \Gamma$. Indeed, choose representatives $h_1, \ldots, h_n$ of the right $\Gamma$-cosets contained in $\Gamma g^{-1} \Gamma$. Since the action of $\Gamma$ is proper, there exists a neighbourhood $U$ of $x$ such that $h_i U \cap \gamma h_j U \neq \emptyset$ for some $i$, $j$ and $\gamma \in \Gamma$ then $h_i x = \gamma h_j x$. But since the action of $G$ is free, the latter equality is possible only when $h_i = \gamma h_j$, so that $i = j$ and $\gamma = e$. Thus $h_i U \cap \gamma h_i U = \emptyset$ if $i \neq j$ or $\gamma \neq e$. Since $\Gamma g^{-1} \Gamma = \bigcup_{k=1}^n \Gamma h_k$, this proves the claim.

The set $\Gamma g^{-1} \Gamma U$ is therefore a disjoint union of the sets $hU$, $h \in \Gamma g^{-1} \Gamma$. So we can write

$$\sum_{h \in \Gamma \backslash \Gamma g^{-1} \Gamma} 1_{h^{-1} \Gamma U} = 1_{\Gamma g^{-1} \Gamma U} = \sum_{h \in \Gamma \backslash \Gamma g^{-1} \Gamma} 1_{\Gamma h U}.$$

Denoting by $p : X \to \Gamma \backslash X$ the quotient map, we can rewrite the above in terms of functions on $\Gamma \backslash X$ as

$$R_\Gamma(g) T_g (1_{p(U)}) = 1_{p(\Gamma g^{-1} \Gamma U)} = \sum_{h \in \Gamma \backslash \Gamma g^{-1} \Gamma} 1_{p(hU)}.$$

It follows that

$$R_\Gamma(g) \int_{\Gamma \backslash X} T_g (1_{p(U)}) d\nu = \sum_{h \in \Gamma \backslash \Gamma g^{-1} \Gamma} \nu(p(hU)) = \sum_{h \in \Gamma \backslash \Gamma g^{-1} \Gamma} \mu(hU) = R_\Gamma(g^{-1}) N(g)^{\beta} \nu(p(U)).$$

In other words, the identity in the lemma holds for $f = 1_{p(U)}$. Since this is true for any $x$ and sufficiently small neighbourhood $U$ of $x$, we get the result.

Notice that by applying the above lemma to the characteristic function of $X$ we get the following: if a group $G$ acts freely on a space $X$ with a $G$-invariant measure $\mu$, and $\Gamma$ is an almost normal subgroup of $G$ (that is, $(G, \Gamma)$ is a Hecke pair) such that the action of $\Gamma$ on $X$ is proper and $0 < \mu(\Gamma \backslash X) < \infty$, then $\Delta_\Gamma(g) = 1$ for any $g \in G$. The same is true if we assume that the action of $G$ on $(X, \mu)$ is only essentially free.

Lemma 2.7. Suppose $\mu$ is as in Proposition 2.4 and $\nu$ is the measure on $\Gamma \backslash Y$ determined by (2.2).

Assume the action of $G$ on $X$ is free and that $(G, \Gamma)$ is a Hecke pair. Assume further that $Y_0$ is a $\Gamma$-invariant measurable subset of $Y$ such that if $gY_0 \cap Y_0 \neq \emptyset$ for some $g \in G$ then $g \in \Gamma$. Then for any $g \in G$ such that $gY_0 \subset Y$, measurable $Z \subset \Gamma \backslash Y_0$ and positive measurable function $f$ on $\Gamma \backslash Y$ we have

$$\int_{\Gamma \backslash Z} f d\nu = N(g)^{-\beta} R_\Gamma(g) \int_{Z} T_g f d\nu,$$
where $\Gamma gZ = p(\Gamma gp^{-1}(Z))$ and $p: X \rightarrow \Gamma \backslash X$ is the quotient map. In particular, $\nu(\Gamma gZ) = N(g)^{-\beta} R_\Gamma(g) \nu(Z)$.

Proof. Suppose $Z \subset \Gamma \backslash Y_0$ is measurable, and choose $U \subset Y_0$ measurable such that $Z = p(U)$ and $p$ is injective on $U$. For $g \in G$ let $h_1, \ldots, h_n$ be representatives of the right $\Gamma$-cosets contained in $\Gamma g \Gamma$. We claim that the map $p$ is injective on $h_1 U, \ldots, h_n U$, and the images of these sets are disjoint. Indeed, assume $p(h_i x) = p(h_j y)$ for some $i, j$ and $x, y \in U$, so that $\gamma h_i x = h_j y$ for some $\gamma \in \Gamma$. Since $U \subset Y_0$, our assumption on $Y_0$ implies $h_j^{-1} \gamma h_i = e$. But then, since $p$ is injective on $U$, we get $x = y$, and since the action of $\Gamma$ is free, we conclude that $h_j^{-1} \gamma h_i = e$. It follows that $i = j$ and $h_i x = h_j y$, which proves the claim.

Furthermore, the union of the disjoint sets $p(h_1 U), \ldots, p(h_n U)$ is the set $\Gamma g Z = p(\Gamma gp^{-1}(Z))$. Hence, since $N(h_i) = N(g)$ for $i = 1, \ldots, n$,

$$\int_{\Gamma g Z} f \, d\nu = \sum_{i=1}^{n} \int_{h_i U} f \circ p \, d\mu = N(g)^{-\beta} \sum_{i=1}^{n} \int_{U} f(p(h_i^{-1} \cdot)) \, d\mu = N(g)^{-\beta} R_\Gamma(g) \int_{Z} T_g f \, d\nu.$$ 

The last assertion of the lemma follows by taking $f = 1_{\Gamma g Z}$ and observing that then $(T_g f)(z) = 1$ for $z \in Z$. \hfill $\square$

To formulate the next lemma we introduce the following notation.

**Definition 2.8.** If $\beta \in \mathbb{R}$ and $S$ is a subsemigroup of $G$ containing $\Gamma$, then we define

$$\zeta_{S, \Gamma} (\beta) := \sum_{s \in \Gamma \backslash S} N(s)^{-\beta} = \sum_{s \in \Gamma \backslash S / \Gamma} N(s)^{-\beta} R_\Gamma(s).$$

**Lemma 2.9.** Suppose $\mu$ is as in Proposition 2.7 and $\nu$ is the measure on $\Gamma \backslash Y$ determined by (2.2). Assume that the action of $G$ on $X$ is free and that $(G, \Gamma)$ is a Hecke pair. Assume further that $Y_0$ is a measurable $\Gamma$-invariant subset of $Y$, and $S$ a subsemigroup of $G$ containing $\Gamma$ such that

(i) if $gY_0 \cap Y_0 \neq \emptyset$ for some $g \in G$ then $g \in \Gamma$;

(ii) $\cup_{s \in S} sY_0$ is a subset of $Y$ of full measure;

(iii) $\zeta_{S, \Gamma}(\beta) < \infty$.

Let $H_S$ be the subspace of $S$-invariant functions in $L^2(\Gamma \backslash Y, \nu)$, that is, functions $f$ such that $f(y) = f(sy)$ for all $s \in S$ and a.a. $y \in Y$. Then

1. if $f \in H_S$ then $\|f\|_2^2 = \zeta_{S, \Gamma}(\beta) \int_{\Gamma \backslash Y_0} |f(t)|^2 \, d\nu(t)$;

2. the orthogonal projection $P: L^2(\Gamma \backslash Y, d\nu) \rightarrow H_S$ is given by

$$Pf|_{S} = \zeta_{S, \Gamma}(\beta)^{-1} \sum_{s \in \Gamma \backslash S / \Gamma} N(s)^{-\beta} R_\Gamma(s) (T_s f)(y) \quad \text{for} \quad y \in Y_0.$$  

**Proof.** By condition (i) the sets $\Gamma s Y_0$ are disjoint for $s$ in different double cosets of $\Gamma$. Since the union of such sets is the whole space $Y$ (modulo a set of measure zero), by Lemma 2.7 applied to $Z = \Gamma \backslash Y_0$ for any $f \in L^2(\Gamma \backslash Y, d\nu)$ we get

$$\|f\|_2^2 = \sum_{s \in \Gamma \backslash S / \Gamma} \int_{\Gamma \backslash S Z} |f|^2 \, d\nu = \sum_{s \in \Gamma \backslash S / \Gamma} N(s)^{-\beta} R_\Gamma(s) \int_{\Gamma \backslash Y_0} T_s (|f|^2) \, d\nu.$$  

Since $T_s (|f|^2) = |f|^2$ for $f \in H_S$, this gives (1).

Turning to (2), denote by $T$ the operator on $L^2(\Gamma \backslash Y, d\nu)$ defined by the asserted formula for $P$. To see that it is well-defined, notice first that the summation in the right hand side of (2.3) is finite for $f$ in the subspace of $L^2$-functions supported on a finite collection of sets of the form $p(sY_0)$,
by Möbius transformations on the upper halfplane of \( \text{GL}_2 \) on the left. Moreover, by considering the diagonal embedding of a subgroup \( \text{GL}_2^+ \) of \( \text{GL}_2(Q) \) into \( \text{SL}_2 \) of adeles of \( Q \), we get an embedding of \( \text{GL}_2^+ \) into \( \text{GL}_2(Q) \), and thus an action of \( \text{GL}_2(Q) \) on \( \text{Mat}_2(\mathbb{A}_f) \). In addition, \( \text{GL}_2(Q) \) acts on the upper halfplane \( \mathbb{H} \). Therefore we have an action of \( \text{GL}_2(Q) \) on \( \mathbb{H} \times \text{Mat}_2(\mathbb{A}_f) \) such that for \( g = \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \), \( \tau \in \mathbb{H} \) and \( m = (m_p)_p \in \text{Mat}_2(\mathbb{A}_f) \),

\[
g(\tau, (m_p)_p) = \left( \begin{array}{c} a\tau + b \\ c\tau + d \end{array} \right)^p \left( gm_p \right)_p.
\]

Note that the action of \( \text{SL}_2(Q) \) is proper, since already the action of \( \text{SL}_2(Q) \) on \( \mathbb{H} \) is proper.

The \( \text{GL}_2 \)-system of Connes and Marcolli is now defined as follows, see [5, Section 1.8].

**Definition 3.1.** The Connes-Marcolli algebra is the \( C^* \)-algebra \( A = C^*_r(\Gamma \setminus \mathbb{H} \times \mathbb{R} \times Y) \), where \( G = \text{GL}_2(Q) \), \( \Gamma = \text{SL}_2(Z) \), \( G \) acts diagonally on \( X = \mathbb{H} \times \text{Mat}_2(\mathbb{A}_f) \), and \( Y = \mathbb{H} \times \text{Mat}_2(\mathbb{Z}) \). The dynamics \( \sigma \) on \( A \) is defined by the homomorphism \( N : \text{GL}_2(Q) \to \mathbb{R}_+^*, N(g) = |\det(g)| \).

Notice that since \( \Gamma \setminus \mathbb{H} \) is not compact, the algebra \( A \) is nonunital.

By [5] Lemma 1.28 the action of \( \text{GL}_2^+(Q) \) on \( X \setminus (\mathbb{H} \times \{0\}) \) is free. Recall briefly the reason. If \( gm = m \) for some prime number \( p \) and nonzero \( m \in \text{Mat}_2(Q_p) \) then the spectrum of the matrix \( g \) contains 1, and hence \( g \) is conjugate in \( \text{GL}_2^+(Q) \) to an upper-triangular matrix. But then \( g \) has no fixed points in \( \mathbb{H} \).

Although the action of \( \text{GL}_2(Q) \) on \( \mathbb{H} \times \{0\} \) is not free, this set can be ignored in the analysis of KMS\( _\beta \)-states for \( \beta \neq 0 \), see the proof of [5, Proposition 1.30]. Again, recall briefly what happens. Consider the action of \( G \) on \( \tilde{X} = X \setminus (\mathbb{H} \times \{0\}) \), put \( \tilde{Y} = Y \setminus (\mathbb{H} \times \{0\}) \subset \tilde{X} \), and then define \( I = C^*_r(\Gamma \setminus G \setminus \tilde{X} \setminus \tilde{Y}) \). Then \( I \) can be considered as an ideal in \( A \), and the quotient algebra \( A/I \) is isomorphic to \( C^*_r(\Gamma \setminus G \setminus \mathbb{H}) \). Now if \( \varphi \) is a \( \sigma \)-KMS\( _\beta \)-state on \( A \), the restriction \( \varphi|_I \) canonically extends to a KMS-functional on the multiplier algebra of \( I \). Thus we get a KMS-functional \( \tilde{\varphi} \leq \varphi \) on \( A \). If \( \tilde{\varphi} \neq \varphi \) then \( \varphi - \tilde{\varphi} \) is a positive nonzero KMS-functional on \( A \) which vanishes on \( I \). Hence we get a KMS-state on \( A/I \cong C^*_r(\Gamma \setminus G \times \mathbb{R} \setminus \mathbb{H}) \). By Lemma 1.3 the multiplier algebra of \( C^*_r(\Gamma \setminus G \times \mathbb{R} \setminus \mathbb{H}) \) contains the reduced Hecke \( C^* \)-algebra \( C^*_p(G, \Gamma) \). The latter algebra contains in turn the \( C^* \)-algebra of \( \mathbb{Z}(G)/\mathbb{Z}(G \cap \Gamma) \), where \( \mathbb{Z}(G) \) is the center of \( \text{GL}_2^+(Q) \), that is, the group of scalar matrices. But since the dynamics scales nontrivially some unitaries in this algebra, the algebra can not have any
Lemma 3.3. Every double coset of $$g$$ concludes that $$a, d$$ for any $$g$$ that if $$p$$ prime of $$p$$ of $$p$$, we can apply Proposition 3.1 and conclude that there is a one-to-one correspondence between $$\text{KMS}_3$$-weights on $$I$$ with domain of definition containing $$C_c(\Gamma \setminus \hat{Y})$$ and measures $$\mu$$ on $$\hat{Y} = \mathbb{H} \times \text{Mat}_2(\mathbb{Z})^\times$$ such that $$\mu(gZ) = \det(g)^{-\beta} \mu(Z)$$ if both $$Z$$ and $$gZ$$ are subsets of $$\hat{Y}$$. By Lemma 3.2, we can uniquely extend any such measure to a measure on $$X = G\hat{Y} = \mathbb{H} \times \text{Mat}_2(\mathbb{Z})^\times$$ such that $$\mu(gZ) = \det(g)^{-\beta} \mu(Z)$$ for $$Z \subset X$$. To get a state on $$I = C_c^*(\Gamma \setminus G \mathbb{H}\setminus \hat{Y})$$ we need the normalization condition $$\mu(\Gamma \setminus \hat{Y}) = 1$$ (that is, the $$\Gamma$$-invariant measure $$\mu$$ on $$\hat{Y}$$ defines a probability measure on $$\Gamma \setminus \hat{Y}$$). Note also that if $$\beta \neq 0$$ and we have a measure on $$X = \mathbb{H} \times \text{Mat}_2(\mathbb{A}_f)$$ with the same properties as above, then $$\mathbb{H} \times \text{Mat}_2(\mathbb{A}_f)^\times$$ is a subset of full measure, since scalar matrices act trivially on $$\mathbb{H}$$ and so $$\mathbb{H}$$ cannot support a measure scaled nontrivially by them.

Summarizing the above discussion we get the following.

Proposition 3.2. For $$\beta \neq 0$$ there is a one-to-one correspondence between $$\sigma$$-$$\text{KMS}_3$$-states on the Connes-Marcolli system and $$\Gamma$$-invariant measures $$\mu$$ on $$\mathbb{H} \times \text{Mat}_2(\mathbb{A}_f)$$ such that

$$\mu(\Gamma \setminus (\mathbb{H} \times \text{Mat}_2(\mathbb{Z}))) = 1$$ and $$\mu(gZ) = \det(g)^{-\beta} \mu(Z)$$

for any $$g \in \text{GL}_2^+(\mathbb{Q})$$ and compact $$Z \subset \mathbb{H} \times \text{Mat}_2(\mathbb{A}_f)$$.

Denote by $$\text{Mat}_2^+(\mathbb{A}_f)$$ the set of matrices $$m = (m_p)_p \in \text{Mat}_2(\mathbb{A}_f)$$ such that $$\det(m_p) \neq 0$$ for every prime $$p$$. Notice that $$\text{Mat}_2^+(\mathbb{A}_f)$$ is the set of non zero-divisors in $$\text{Mat}_2(\mathbb{A}_f)$$. Our next goal is to show that if $$\beta \neq 0$$, then $$\mathbb{H} \times \text{Mat}_2^+(\mathbb{A}_f)$$ is a subset of full measure for any measure $$\mu$$ as in Proposition 3.2.

First let us recall the following simple properties of the Hecke pair $$(G, \Gamma) = (\text{GL}_2^+(\mathbb{Q}), \text{SL}_2(\mathbb{Z}))$$.

Put $$\text{Mat}_2^+(\mathbb{Z}) = \text{GL}_2^+(\mathbb{Q}) \cap \text{Mat}_2(\mathbb{Z})$$.

Lemma 3.3. Every double coset of $$\Gamma$$ in $$\text{Mat}_2^+(\mathbb{Z})$$ has a unique representative of the form

$$\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}$$

with $$a, d \in \mathbb{N}$$ and $$a|d$$. Furthermore,

$$R_\Gamma \begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix} = \frac{d}{a} \prod_{p \text{ prime: } pa|d} (1 + p^{-1}),$$

and as representatives of the right cosets of $$\Gamma$$ contained in $$\Gamma \begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix} \Gamma$$ we can take the matrices

$$\begin{pmatrix} ak & am \\ 0 & ad \end{pmatrix}$$

with $$k, l \in \mathbb{N}$$ and $$m \in \mathbb{Z}$$ such that $$kl = d/a$$, $$0 \leq m < l$$ and $$\gcd(k, l, m) = 1$$.

In particular, $$R_\Gamma(g) = R_\Gamma(g^{-1})$$ for every $$g \in \text{GL}_2^+(\mathbb{Q})$$.

Proof. See e.g. [13 Chapter IV].

For a prime $$p$$ put $$G_p = \text{GL}_2^+(\mathbb{Z}[p^{-1}]) \subset \text{GL}_2^+(\mathbb{Q})$$. Observe that if $$g \in G_p$$ then $$\det(g)$$ is a power of $$p$$, and if we multiply $$g$$ by a sufficiently large power of $$\begin{pmatrix} p & 0 \\ 0 & p \end{pmatrix}$$, we get an element in $$\text{Mat}_2^+(\mathbb{Z})$$ with determinant a power of $$p$$. But by Lemma 3.3 the double coset of $$\Gamma$$ containing such an element has a representative of the form $$\begin{pmatrix} p^k & 0 \\ 0 & p^l \end{pmatrix}$$, $$0 \leq k \leq l$$. We may therefore conclude that $$G_p$$ is the subgroup of $$\text{GL}_2^+(\mathbb{Q})$$ generated by $$\Gamma$$ and $$\begin{pmatrix} 1 & 0 \\ 0 & p \end{pmatrix}$$. Using that a positive rational number is a power of $$p$$ if and only if it belongs to the group of units $$\mathbb{Z}_q^\times$$ of the ring $$\mathbb{Z}_q$$ for all primes $$q \neq p$$, we may also conclude that $$g \in \text{GL}_2^+(\mathbb{Q})$$ belongs to $$G_p$$ if and only if it belongs to $$\text{GL}_2(\mathbb{Z}_q)$$ for all $$q \neq p$$. \hfill \square
Lemma 3.4. We have $GL_2(Q_p) = G_pGL_2(Z_p)$.

Proof. Let $r \in GL_2(Q_p)$. Then $rZ_p^2$ is a $Z_p$-lattice in $Q_p^2$, that is, an open compact $Z_p$-submodule. By [22, Theorem V.2] there exists a subgroup $L \cong Z^2$ of $Q^2$ such that the closure of $L$ in $Q_p^2$ coincides with $rZ_p^2$, and the closure of $L$ in $Z_q^2$ for $q \neq p$. Choose $g \in GL_2^+(Q)$ such that $gZ^2 = L$. Since $gZ_q^2 = rZ_p^2$, we have $g^{-1}r \in GL_2(Z_p)$. Since $gZ_q^2 = Z_q^2$ for $q \neq p$, we also have $g \in GL_2(Z_q)$. Hence $g \in G_p$. 

It is also possible to give an elementary proof of Lemma 3.4 using matrix factorization and density of $Z[p^{-1}]$ in $Q_p$.

Lemma 3.5. Let $p$ be a prime and $\mu_p$ a $\Gamma$-invariant measure on $\mathbb{H} \times Mat_2(Q_p)$ such that

$$\mu_p(\mathbb{H} \times \{0\}) = 0, \quad \mu_p(\Gamma \setminus (\mathbb{H} \times Mat_2(Z_p))) < \infty \quad \text{and} \quad \mu_p(gZ) = \det(g)^{-\beta} \mu_p(Z)$$

for $g \in G_p$ and $Z \subset \mathbb{H} \times Mat_2(Q_p)$. If $\beta \neq 1$, then the set $\mathbb{H} \times GL_2(Q_p)$ is a subset of full measure in $\mathbb{H} \times Mat_2(Q_p)$.

Proof. Denote by $\tilde{\nu}$ the measure on $\Gamma \setminus (\mathbb{H} \times Mat_2(Q_p))$ defined by the $\Gamma$-invariant measure $\mu_p$. For a $\Gamma$-invariant subset $Z$ of $Mat_2(Q_p)$, the set $\mathbb{H} \times Z$ is $\Gamma$-invariant. We can thus define a measure $\nu$ on the $\sigma$-algebra of $\Gamma$-invariant Borel subsets of $Mat_2(Q_p)$ by $\nu(Z) = \tilde{\nu}(\Gamma \setminus (\mathbb{H} \times Z))$. Note that since the action of $\Gamma$ on $Mat_2(Q_p)$ is not proper and, accordingly, the quotient space $\Gamma \setminus Mat_2(Q_p)$ is quite bad, we do not want to consider $\Gamma$-invariant subsets of $Mat_2(Q_p)$ as subsets of this quotient space, and do not try to define a measure on all Borel subsets of $Mat_2(Q_p)$ out of $\nu$.

If $g \in G_p$ and $f$ is a positive Borel $\Gamma$-invariant function on $Mat_2(Q_p)$ then by Lemma 2.6 applied to the function $F: (\tau, m) \mapsto f(m)$ on $\Gamma \setminus (\mathbb{H} \times Mat_2(Q_p))$ we conclude that

$$\int_{Mat_2(Q_p)} T_g f d\nu = \int_{\Gamma \setminus (\mathbb{H} \times Mat_2(Q_p))} T_g F d\tilde{\nu} = \det(g)^{\beta} \int_{\Gamma \setminus (\mathbb{H} \times Mat_2(Q_p))} F d\tilde{\nu} = \det(g)^{\beta} \int_{Mat_2(Q_p)} f d\nu.$$ (3.1)

By assumption we also have $\nu(Mat_2(Z_p)) < \infty$. We have to show that the measure of the set of nonzero singular matrices is zero.

We claim that the set of nonzero singular matrices with coefficients in $Q_p$ is the disjoint union of the sets

$$Z_k = SL_2(Z_p) \left( \begin{array}{cc} 0 & 0 \\ 0 & p^k \end{array} \right) GL_2(Z_p), \quad k \in \mathbb{Z}.$$ 

This is proved in a standard way: given a nonzero singular matrix we use multiplication by elements of $GL_2(Z_p)$ on the right to get a matrix with zero first column, and then multiplication by elements of $SL_2(Z_p)$ on the left to get the required form. To show that the sets do not intersect, observe that the maximum of the $p$-adic valuations of the coefficients of a matrix does not change under multiplication by elements of $GL_2(Z_p)$ on either side.

Consider the functions $f_k = 1_{Z_k}, \quad k \in \mathbb{Z}. \quad \text{For} \quad g = \left( \begin{array}{cc} 1 & 0 \\ 0 & p^{-1} \end{array} \right) \quad \text{we claim that} \quad T_g f_0 = \frac{1}{p+1} f_0 + \frac{p}{p+1} f_1.$

Indeed, since the action of $G_p$ commutes with the right action of $GL_2(Z_p)$, the function $T_g f_0$ is $GL_2(Z_p)$-invariant. On the other hand, the sets $Z_k$ are clopen subsets of the set of singular matrices, so that the function $f_0$ is continuous on this set. But then $T_g f_0$ is also continuous. Since $T_g f_0$ is $\Gamma$-invariant, and $\Gamma$ is dense in $SL_2(Z_p)$ (see e.g. [20, Lemma 1.38] for an elementary proof of a stronger result: $\Gamma$ is dense in $SL_2(\mathbb{Z})$), we conclude that $T_g f_0$ is left $SL_2(Z_p)$-invariant. Hence $T_g f_0$
is constant on the sets $Z_k$. So to prove the above identity it suffices to check it on the matrices 
\[
\begin{pmatrix} 0 & 0 \\ 0 & p^k \end{pmatrix}.
\]
Since $g = \begin{pmatrix} p^{-1} & 0 \\ 0 & p \end{pmatrix} \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix}$, by Lemma 3.3 we can take the matrices 
\[
\begin{pmatrix} 1 & 0 \\ 0 & p^{-1} \end{pmatrix}, \quad \begin{pmatrix} p^{-1} & np^{-1} \\ 0 & 1 \end{pmatrix}, \quad 0 \leq n \leq p - 1,
\]
as representatives of the right cosets of $\Gamma$ contained in $\Gamma$. Then 
\[
(T_g f_0) \begin{pmatrix} 0 & 0 \\ 0 & p^k \end{pmatrix} = \frac{1}{p+1} f_0 \begin{pmatrix} 0 & 0 \\ 0 & p^{k-1} \end{pmatrix} + \frac{1}{p+1} \sum_{n=0}^{p-1} f_0 \begin{pmatrix} 0 & np^{k-1} \\ 0 & p^k \end{pmatrix}.
\]
Since the matrices 
\[
\begin{pmatrix} 0 & 0 \\ 0 & p^{k-1} \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & np^{k-1} \\ 0 & p^k \end{pmatrix}, \quad 1 \leq n \leq p - 1,
\]
belong to $Z_{k-1}$, we see that 
\[
T_g f_0|_{Z_1} = \frac{p}{p+1}, \quad T_g f_0|_{Z_0} = \frac{1}{p+1}, \quad T_g f_0|_{Z_k} = 0 \quad \text{for} \quad k \neq 0, 1,
\]
and this is exactly what we claimed.

It follows from (3.1) that 
\[
p^{-\beta} \nu(Z_0) = \frac{1}{p+1} \nu(Z_0) + \frac{p}{p+1} \nu(Z_1).
\]
On the other hand, for $g = \begin{pmatrix} p^{-1} & 0 \\ 0 & p^{-1} \end{pmatrix}$ we get $T_g f_k = f_{k+1}$, so that 
\[
p^{-2\beta} \nu(Z_k) = \nu(Z_{k+1}).
\]
If $\nu(Z_0) \neq 0$ this implies that $p^{-\beta}$ is a solution of the quadratic equation 
\[
(p+1)x = 1 + px^2,
\]
Thus either $p^{-\beta} = p^{-1}$ or $p^{-\beta} = 1$. Since $\beta \neq 1$ we get $\beta = 0$. But then $\nu(Z_k) = \nu(Z_0)$ for any $k$, and this contradicts $\nu(\text{Mat}_2(\mathbb{Z}_p)) < \infty$. The contradiction shows that $\nu(Z_0) = 0$. Hence $\nu(Z_k) = 0$ for any $k$, and we conclude that the measure of the set of singular matrices is zero.

We are now ready to show that for $\beta \neq 0, 1$ the set $\text{Mat}_2(\mathbb{A}_f) \setminus \text{Mat}_2(\mathbb{A}_f)$ of zero-divisors has measure zero.

**Corollary 3.6.** Assume $\beta \neq 0, 1$ and $\mu$ is a measure with properties as in Proposition 3.2. Then $\mathbb{H} \times \text{Mat}_2(\mathbb{A}_f)$ is a subset of full measure in $\mathbb{H} \times \text{Mat}_2(\mathbb{A}_f)$.

**Proof.** Fix a prime $p$. First of all note that the set 
\[
\{ (\tau, m) \in \mathbb{H} \times \text{Mat}_2(\mathbb{A}_f) \mid m_p = 0 \}
\]
has measure zero. Indeed, as we already remarked before Proposition 3.2 the set $\mathbb{H} \times \{0\}$ has measure zero. So if our claim is not true, the set 
\[
\{ (\tau, m) \in \mathbb{H} \times \text{Mat}_2(\mathbb{Z})_\infty \mid m_p = 0 \}
\]
has positive measure. Since the action of $\Gamma$ on this set is free, there is a subset $U$ of positive measure such that $\gamma U \cap U = \emptyset$ for $\gamma \in \Gamma$, $\gamma \neq e$. Then for $g = \begin{pmatrix} p & 0 \\ 0 & p \end{pmatrix}$ the set $U_k = g^k U$, $k \in \mathbb{Z}$, still has the property that $\gamma U_k \cap U_k = \emptyset$ for $\gamma \in \Gamma$, $\gamma \neq e$, since $g$ commutes with $\Gamma$. As $U_k$ is contained in $\mathbb{H} \times \text{Mat}_2(\mathbb{Z})_\infty$, it follows that $\mu(U_k) \leq 1$. On the other hand, $\mu(U_k) = p^{-2\beta k} \mu(U)$. Letting $k \to -\infty$ if $\beta > 0$ and $k \to +\infty$ if $\beta < 0$, we get a contradiction.

Consider now the restriction of $\mu$ to the set 
\[
\mathbb{H} \times \text{Mat}_2(\mathbb{Q}_p) \times \prod_{q \neq p} \text{Mat}_2(\mathbb{Z}_q),
\]
and use the projection onto the first two factors to get a measure $\mu_p$ on $H \times \text{Mat}_2(\mathbb{Q}_p)$. By the first part of the proof the set $H \times \{0\}$ has $\mu_p$-measure zero. Since the image of $G_p$ in $GL_2(\mathbb{Q}_q)$ lies in $GL_2(\mathbb{Z}_q)$ for $q \neq p$, the scaling property of $\mu$ implies that

$$\mu_p(gZ) = \det(g)^{-\beta}\mu_p(Z) \quad \text{for} \quad Z \subset H \times \text{Mat}_2(\mathbb{Q}_p), \ g \in G_p.$$ 

Since the action of $\Gamma$ on $H \times \text{Mat}_2(\mathbb{Q}_p)^\times$ is free, the normalization condition on $\mu$ implies that $\mu_p(\Gamma \backslash (H \times \text{Mat}_2(\mathbb{Z}_P))) = 1$. Thus $\mu_p$ satisfies the assumptions of Lemma 3.3. Hence $H \times GL_2(\mathbb{Q}_p)$ is a set of full $\mu_p$-measure. This means that the set of points $(\tau, m) \in H \times \text{Mat}_2(\hat{\mathbb{Z}})$ with $\det(m_p) = 0$ has $\mu$-measure zero. By taking the union of such sets for all primes $p$ and multiplying it by elements of $GL_2^+(\mathbb{Q})$ we get a set of measure zero, which is the complement of the set $H \times \text{Mat}_2^+(\mathbb{A}_f)$.  

To get further properties of a measure $\mu$ as above, let us recall the following well-known computation, see e.g. [20, Section 3.2] for more general results on formal Dirichlet series. Denote by $S_p$ the semigroup $G_p \cap \text{Mat}_2^+(\mathbb{Z})$. Alternatively, $S_p$ is the set of elements $m \in \text{Mat}_2^+(\mathbb{Z})$ with determinant a nonnegative power of $p$. Then from Lemma 3.3 we know that as representatives of the right cosets of $\Gamma$ in $S_p$ we can take the matrices $\left(\begin{array}{cc} p^k & m \\ 0 & p^l \end{array}\right)$, $k, l \geq 0$, $0 \leq m < p^l$. Therefore

$$\zeta_{S_p, \Gamma}(\beta) = \sum_{s \in \Gamma \backslash S_p} \frac{\det(s)^{-\beta}}{s} = \sum_{k, l = 0}^{\infty} p^{-\beta(k+l)}p^l = \begin{cases} +\infty, & \text{if } \beta \leq 1, \\ (1-p^{-\beta})^{-1}(1-p^{-\beta+1})^{-1}, & \text{if } \beta > 1. \end{cases} \quad (3.2)$$

Since $\Gamma = G_p \cap GL_2(\mathbb{Z}_p)$, we can apply Lemma 2.3 to the group $G_p$ acting on $H \times \text{Mat}_2(\mathbb{A}_f)^\times$ and the set

$$Y_0 = H \times GL_2(\mathbb{Z}_p) \times \prod_{q \neq p} \text{Mat}_2(\mathbb{Z}_q).$$

Then for any $s \in S_p$ we get

$$\mu(\Gamma \backslash GsY_0) = \det(s)^{-\beta} R_\Gamma(s) \mu(\Gamma \backslash Y_0).$$

The sets $\Gamma sY_0$ are disjoint for $s$ in different double cosets of $\Gamma$, and their union is the set

$$H \times \text{Mat}_2^+(\mathbb{Z}_p) \times \prod_{q \neq p} \text{Mat}_2(\mathbb{Z}_q),$$

where $\text{Mat}_2^+(\mathbb{Z}_p) = \text{Mat}_2(\mathbb{Z}_p) \cap GL_2(\mathbb{Q}_p)$. By Corollary 3.6 the above set is a subset of $H \times \text{Mat}_2(\hat{\mathbb{Z}})$ of full measure for $\beta \neq 0, 1$. Therefore we obtain

$$1 = \sum_{s \in \Gamma \backslash S_p/\Gamma} \mu(\Gamma \backslash GsY_0) = \sum_{s \in \Gamma \backslash S_p/\Gamma} \det(s)^{-\beta} R_\Gamma(s) \mu(\Gamma \backslash Y_0) = \zeta_{S_p, \Gamma}(\beta) \mu(\Gamma \backslash Y_0). \quad (3.3)$$

This gives a contradiction if $\beta < 1$. Thus for $\beta < 1$, $\beta \neq 0$, there are no KMS$_\beta$-states. On the other hand, for $\beta > 1$ we get

$$\mu(\Gamma \backslash Y_0) = \zeta_{S_p, \Gamma}(\beta)^{-1} = (1-p^{-\beta})(1-p^{-\beta+1}).$$

Assuming now that $\beta > 1$ we can perform a similar computation for any finite set of primes instead of just one prime. Given a finite set $F$ of primes consider the group $G_F$ generated by $G_p$ for all $p \in F$. Put also $S_F = \text{Mat}_2^+(\mathbb{Z}) \cap G_F$. Then $S_F$ is the set of matrices $m \in \text{Mat}_2^+(\mathbb{Z})$ such that all prime divisors of $\det(m)$ belong to $F$. Let

$$Y_F = H \times \left(\prod_{p \in F} GL_2(\mathbb{Z}_p)\right) \times \left(\prod_{q \notin F} \text{Mat}_2(\mathbb{Z}_q)\right).$$

Then a computation similar to (3.2) and (3.3) yields

$$\zeta_{S_F, \Gamma}(\beta) = \prod_{p \in F} (1-p^{-\beta})^{-1}(1-p^{-\beta+1})^{-1} \quad \text{and} \quad \mu(\Gamma \backslash Y_F) = \prod_{p \in F} (1-p^{-\beta})(1-p^{-\beta+1}). \quad (3.4)$$
The intersection of the sets $Y_F$ over all finite subsets $F$ of prime numbers is the set $\mathbb{H} \times \text{GL}_2(\mathbb{Z})$. So for $\beta > 2$ we get

$$
\mu(\Gamma \setminus (\mathbb{H} \times \text{GL}_2(\mathbb{Z}))) = \prod_p (1 - p^{-\beta})(1 - p^{-\beta+1}) = \zeta(\beta)^{-1}\zeta(\beta - 1)^{-1},
$$

where $\zeta$ is the Riemann $\zeta$-function. On the other hand, for $\beta \in (1, 2]$ we get $\mu(\Gamma \setminus (\mathbb{H} \times \text{GL}_2(\mathbb{Z}))) = 0$.

Assume now that $\beta > 2$. In this case similarly to (3.2) we have

$$
\zeta_{\text{Mat}^+_2}(Z,\Gamma(\beta)) = \zeta(\beta)\zeta(\beta - 1).
$$

So analogously to (3.3) we get

$$
\mu(\Gamma \setminus \text{Mat}^+_2(Z)(\mathbb{H} \times \text{GL}_2(\mathbb{Z}))) = \zeta_{\text{Mat}^+_2}(Z,\Gamma)\mu(\Gamma \setminus (\mathbb{H} \times \text{GL}_2(\mathbb{Z}))) = 1.
$$

We thus see that $\text{Mat}^+_2(Z)(\mathbb{H} \times \text{GL}_2(\mathbb{Z}))$ is a subset of $\mathbb{H} \times \text{Mat}_2(\mathbb{Z})$ of full measure. Hence $\text{GL}_2^+(\mathbb{Q})(\mathbb{H} \times \text{GL}_2(\mathbb{Z}))$ is a subset of $\mathbb{H} \times \text{Mat}_2(A_f)$ of full measure. By Lemma 3.4 the set $\text{GL}_2^+(\mathbb{Q})(\mathbb{H} \times \text{GL}_2(\mathbb{Z}))$ is nothing but $\mathbb{H} \times \text{GL}_2(A_f)$.

To summarize, we have shown that for $\beta > 2$ the problem of finding all measures $\mu$ on $\mathbb{H} \times \text{Mat}_2(A_f)$ satisfying the conditions in Proposition 3.2 reduces to finding all measures on $\mathbb{H} \times \text{GL}_2(A_f)$ such that

$$
\mu(gZ) = \det(g)^{-\beta}\mu(Z) \quad \text{and} \quad \mu(\Gamma \setminus (\mathbb{H} \times \text{GL}_2(\mathbb{Z}))) = \zeta(\beta)^{-1}\zeta(\beta - 1)^{-1}.
$$

By Lemma 2.4 any $\Gamma$-invariant measure on $\mathbb{H} \times \text{GL}_2(\mathbb{Z})$ extends uniquely to a measure on $\mathbb{H} \times \text{GL}_2(A_f)$ satisfying the scaling condition. Thus we get a one-to-one correspondence between measures $\mu$ with properties as in Proposition 3.2 and measures on $\Gamma \setminus (\mathbb{H} \times \text{GL}_2(\mathbb{Z}))$ of total mass $\zeta(\beta)^{-1}\zeta(\beta - 1)^{-1}$. Clearly, extremal measures $\mu$ correspond to point masses.

We have thus recovered the following result of Connes and Marcolli [5, Theorem 1.26 and Corollary 1.32].

**Theorem 3.7.** For the Connes-Marcolli $\text{GL}_2$-system we have:

(i) for $\beta \in (-\infty, 0) \cup (0, 1)$ there are no $\text{KMS}_3$-states;

(ii) for $\beta > 2$ there is a one-to-one affine correspondence between $\text{KMS}_3$-states and probability measures on $\Gamma \setminus (\mathbb{H} \times \text{GL}_2(\mathbb{Z}))$; in particular, extremal $\text{KMS}_3$-states are in bijection with $\Gamma$-orbits in $\mathbb{H} \times \text{GL}_2(\mathbb{Z})$.

**Remark 3.8.** This is not exactly what is stated in [5]. First of all, the cases $\beta = 0, 1$ require considerations with singular matrices, and in these cases we do have $\text{KMS}$-states, see Remark 1.8 below. Secondly, the classification of extremal $\text{KMS}_3$-states for $\beta > 2$ in [5, Theorem 1.26] is in terms of invertible $\mathbb{Q}$-lattices up to scaling. To see that our Theorem 3.7(ii) says the same, recall that the isomorphism from [5, Equation (1.87)] identifies $\Gamma \setminus (\mathbb{H} \times \text{GL}_2(\mathbb{Z}))$ with the set of invertible $\mathbb{Q}$-lattices in $\mathbb{C}$ up to scaling, and observe that the state $\varphi_{\beta, l}$ defined in [5, Theorem 1.26(ii)] associated with $l = (\tau, \rho) \in \mathbb{H} \times \text{GL}_2(\mathbb{Z})$ is exactly the $\text{KMS}_3$-state corresponding to the orbit $\Gamma(\tau, \rho)$. Since the $\mathbb{Q}$-lattice picture will not be used in the remaining part of the paper, we omit the details.

4. **Uniqueness of the $\text{KMS}_3$-state in the critical region $1 < \beta \leq 2$**

In this section we analyze the Connes-Marcolli system in the region $\beta \in (1, 2]$.

For each such $\beta$ let us first construct a $\text{KMS}_3$-state, or equivalently, a measure $\mu_\beta$ on $\mathbb{H} \times \text{Mat}_2(A_f)$ satisfying the conditions in Proposition 3.2.
For each prime number $p$ consider the Haar measure on $GL_2(\mathbb{Z}_p)$ normalized such that the total mass is $(1 - p^{-\beta})(1 - p^{-\beta + 1})$. By the same argument as in the proof of Lemma 2.4 this measure extends to a unique measure $\mu_{\beta,p}$ on $GL_2(\mathbb{Q}_p)$ such that

$$\mu_{\beta,p}(Z) = \sum_{g \in GL_2(\mathbb{Z}_p) \setminus GL_2(\mathbb{Q}_p)} |\det(g)|_p^{-\beta} \mu_{\beta,p}(gZ \cap GL_2(\mathbb{Z}_p))$$

for compact $Z \subset GL_2(\mathbb{Q}_p)$, where $|a|_p$ denotes the $p$-adic valuation of $a$. The measure $\mu_{\beta,p}$ satisfies

$$\mu_{\beta,p}(gZ) = |\det(g)|_p^{\beta} \mu_{\beta,p}(Z) \quad \text{for} \quad g \in GL_2(\mathbb{Q}_p).$$

Since $|\det(g)|_p = 1$ for $g \in GL_2(\mathbb{Z}_p)$, it is clear that $\mu_{\beta,p}$ is left $GL_2(\mathbb{Z}_p)$-invariant. But since the Haar measure on $GL_2(\mathbb{Z}_p)$ is biinvariant, we conclude that $\mu_{\beta,p}$ is also right $GL_2(\mathbb{Z}_p)$-invariant. By setting $\mu_{\beta,p}(Z) = \mu_{\beta,p}(Z \cap GL_2(\mathbb{Q}_p))$ for Borel $Z \subset Mat_2(\mathbb{Q}_p)$ we extend $\mu_{\beta,p}$ to a measure on $Mat_2(\mathbb{Q}_p)$. Using that $Mat_2(\mathbb{Z}_p) = S_pGL_2(\mathbb{Z}_p)$, similarly to (3.3) we find

$$\mu_{\beta,p}(Mat_2(\mathbb{Z}_p)) = \zeta S_p(\beta) \mu_{\beta,p}(GL_2(\mathbb{Z}_p)) = 1.$$

Hence we can define a measure on $Mat_2(\mathcal{A}_f)$ by $\mu_{\beta,f} = \prod_p \mu_{\beta,p}$. By construction and Lemma 3.3 this is the unique product-measure such that $\mu_{\beta,f}(Mat_2(\mathbb{Z})) = 1$ and

$$\mu_{\beta,f}(gZr) = \left(\prod_p |\det(gp)|_p\right)^{\beta} \mu_{\beta,f}(Z) \quad (4.1)$$

for $Z \subset Mat_2(\mathcal{A}_f)$, $g = (gp) \in GL_2(\mathcal{A}_f)$ and $r \in GL_2(\mathbb{Z})$. Note that since a Haar measure on the additive group $Mat_2(\mathcal{A}_f)$ is a product-measure satisfying (1.1) with $\beta = 2$, we see that $\mu_{2,f}$ is a Haar measure on $Mat_2(\mathcal{A}_f)$.

Denote by $\mu_\infty$ the unique $GL_2^+(\mathbb{Q})$-invariant measure on $\mathbb{H}$ such that $\mu_\infty(\Gamma \setminus \mathbb{H}) = 1$.

Now put $\mu_\beta = 2\mu_\infty \times \mu_{\beta,f}$. Then $\mu_\beta$ satisfies the conditions in Proposition 3.2 so it corresponds to a KMS$_\beta$-state on the Connes-Marcolli $C^*$-algebra. Indeed, the scaling condition is satisfied since $\prod_p |q|_p = q^{-1}$ for $q \in \mathbb{Q}_+$. The factor 2 is needed for the normalization condition, since the element $-1 \in \Gamma$ acts trivially on $\mathbb{H}$, while $\mu_{\beta,f}(\{\pm 1\} \setminus Mat_2(\mathbb{Z})) = 1/2$.

Note that the construction of $\mu_\beta$ makes sense for all $\beta > 1$.

We can now formulate our main result.

**Theorem 4.1.** For each $\beta \in (1,2]$ the state corresponding to the measure $\mu_\beta$ is the unique KMS$_\beta$-state on the Connes-Marcolli system.

We shall prove a slightly stronger result which may look more natural if one leaves aside the motivation for the Connes-Marcolli system. Namely, we replace $\mathbb{H}$ by $PGL_2^+(\mathbb{R}) = GL_2^+(\mathbb{R})/\mathbb{R}^*$. Recall that $PGL_2^+(\mathbb{R})$ acts transitively on $\mathbb{H}$, and $SO_2(\mathbb{R})/\{\pm 1\}$ is the stabilizer of the point $i \in \mathbb{H}$, so that $\mathbb{H} = PGL_2^+(\mathbb{R})/PSO_2(\mathbb{R})$. Denote by $\bar{\mu}_\infty$ the Haar measure on $PGL_2^+(\mathbb{R})$ normalized such that $\bar{\mu}_\infty(\Gamma \setminus PGL_2^+(\mathbb{R})) = 1$. Define then a measure on $PGL_2^+(\mathbb{R}) \times Mat_2(\mathcal{A}_f)$ by $\bar{\mu}_\beta = 2\bar{\mu}_\infty \times \mu_{\beta,f}$.

**Theorem 4.2.** For $\beta \in (1,2]$ the measure $\bar{\mu}_\beta$ is the unique $\Gamma$-invariant measure on the space $PGL_2^+(\mathbb{R}) \times Mat_2(\mathcal{A}_f)$ such that

$$\bar{\mu}_\beta(\Gamma \setminus (PGL_2^+(\mathbb{R}) \times Mat_2(\mathbb{Z}))) = 1 \quad \text{and} \quad \bar{\mu}_\beta(gZ) = |\det(g)|^{-\beta} \bar{\mu}_\beta(Z)$$

for compact $Z \subset PGL_2^+(\mathbb{R}) \times Mat_2(\mathcal{A}_f)$ and $g \in GL_2^+(\mathbb{Q})$.

Theorem 4.1 follows from the above theorem since every measure $\mu$ on $\mathbb{H} \times Mat_2(\mathcal{A}_f)$ satisfying the conditions in Proposition 3.2 gives rise to a measure $\bar{\mu}$ on $PGL_2^+(\mathbb{R}) \times Mat_2(\mathcal{A}_f)$ satisfying the conditions in Theorem 4.2 by the formula

$$\int_{PGL_2^+(\mathbb{R}) \times Mat_2(\mathcal{A}_f)} f d\bar{\mu} = \int_{\mathbb{H} \times Mat_2(\mathcal{A}_f)} \left(\int_{PSO_2(\mathbb{R})} f(g)dg\right) d\mu,$$
where for \( x = (h, m) \in \text{PGL}_2^+(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f) \) and \( g \in \text{PSO}_2(\mathbb{R}) \) we put \( xg = (hg, m) \), and different measures \( \mu \) give rise to different \( \tilde{\mu} \)'s.

Turning to the proof of Theorem 4.2 our first goal is to show uniqueness of \( \tilde{\mu}_\beta \) under the additional assumption of invariance under the right action of \( \text{GL}_2(\hat{\mathbb{Z}}) \) on \( \text{Mat}_2(\mathbb{A}_f) \).

Let \( F \) be a finite set of prime numbers. Recall that we denote by \( S_F \) the semigroup of matrices \( m \in \text{Mat}_2^+(\mathbb{Z}) \) such that all prime divisors of \( \det(m) \) belong to \( F \). We then introduce an operator \( T_F \) on the space of bounded functions on \( \Gamma \setminus \text{PGL}_2^+(\mathbb{R}) \) by

\[
(T_F f)(\tau) = \zeta_{S_F, \Gamma}(\beta)^{-1} \sum_{s \in \Gamma \setminus S_F / \Gamma} \det(s)^{-\beta} R_\Gamma(s)(T_s f)(\tau). \tag{4.2}
\]

Denote by \( \tilde{\nu}_\infty \) the measure on \( \Gamma \setminus \text{PGL}_2^+(\mathbb{R}) \) defined by \( \bar{\mu}_\infty \). The following result is a key point in our argument for uniqueness of the \( \text{GL}_2(\hat{\mathbb{Z}}) \)-invariant measure.

**Lemma 4.3.** For any finite set \( J \) of prime numbers, \( f \in C_c(\Gamma \setminus \text{PGL}_2^+(\mathbb{R})), \varepsilon > 0 \) and compact subset \( \Omega \subset \Gamma \setminus \text{PGL}_2^+(\mathbb{R}) \), there exists a finite set \( F \) of prime numbers that is disjoint from \( J \) and satisfies

\[
\left| (T_F f)(\tau) - \int_{\Gamma \setminus \text{PGL}_2^+(\mathbb{R})} f d\tilde{\nu}_\infty \right| < \varepsilon \quad \text{for all} \quad \tau \in \Omega.
\]

**Proof.** By [1] Theorem 1.7 and Remark (3) following it, see also [10] for an alternative proof of a slightly weaker result, there exists a constant \( M \) such that

\[
\left| (T_g f)(\tau) - \int_{\Gamma \setminus \text{PGL}_2^+(\mathbb{R})} f d\tilde{\nu}_\infty \right| < \frac{\varepsilon}{2}
\]

for \( \tau \in \Omega \) and any \( g \in \text{GL}_2^+(\mathbb{Q}) \) with \( R_\Gamma(g) > M \). We may assume that \( M \) is such that \( p < M \) for any \( p \in J \). Let \( F \) be a finite set of prime numbers greater than \( M \). Then from Lemma 4.3 we see that \( R_\Gamma(s) > M \) for any \( s \in S_F \) such that \( \Gamma s \Gamma \) contains a nonscalar diagonal matrix. On the other hand,

\[
\sum_{s \in \Gamma \setminus S_F / \Gamma: \text{scalar}} \det(s)^{-\beta} = \prod_{p \in F} \left( \sum_{k=0}^{\infty} p^{-2\beta k} \right) = \prod_{p \in F} (1 - p^{-2\beta})^{-1} \leq \zeta(2\beta).
\]

Since the operators \( T_g \) are contractions in the supremum-norm, we can find \( C > 0 \) such that

\[
\left| (T_g f)(\tau) - \int_{\Gamma \setminus \text{PGL}_2^+(\mathbb{R})} f d\tilde{\nu}_\infty \right| \leq C \quad \text{for} \quad \tau \in \Omega \quad \text{and} \quad g \in \text{GL}_2^+(\mathbb{Q}).
\]

Therefore by considering separately the summation over double cosets with nonscalar and scalar representatives we get

\[
\left| (T_F f)(\tau) - \int_{\Gamma \setminus \text{PGL}_2^+(\mathbb{R})} f d\tilde{\nu}_\infty \right| \leq \frac{\varepsilon}{2} + \frac{\zeta(2\beta)}{\zeta_{S_F, \Gamma}(\beta)} C \quad \text{for any} \quad \tau \in \Omega.
\]

Recall that by [34]

\[
\zeta_{S_F, \Gamma}(\beta) = \prod_{p \in F} (1 - p^{-\beta})^{-1}(1 - p^{-\beta+1})^{-1}.
\]

Since for \( \beta \leq 2 \) this product diverges as \( F \) increases, we see that by choosing sufficiently large \( F \) we can make the second summand in the estimate above arbitrarily small, hence we are done. \( \square \)

We can now analyze the case of measures on \( \text{PGL}_2^+(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f) \) that are invariant under the right action of \( \text{GL}_2(\hat{\mathbb{Z}}) \) on the second factor.
Lemma 4.4. The measure $\mu_\beta$ is the unique right $GL_2(\widehat{\mathbb{Z}})$-invariant measure on $PGL_2^+(\mathbb{R}) \times Mat_2(A_f)$ that satisfies the conditions in Theorem 4.2. Furthermore, the action of $GL_2^+(\mathbb{Q})$ on the space $(PGL_2^+(\mathbb{R}) \times (Mat_2(A_f)/GL(2,\mathbb{Z})), \mu_\beta)$ is ergodic.

Proof. The measure $\mu_\beta$ is right $GL_2(\widehat{\mathbb{Z}})$-invariant and satisfies the conditions in Theorem 4.2 by construction. Suppose $\tilde{\nu}$ is another such measure. Let $\nu$ and $\nu_\beta$ be the measures on the quotient space $\Gamma \backslash (PGL_2^+(\mathbb{R}) \times Mat_2(A_f))$ defined by $\mu$ and $\mu_\beta$, respectively. Let $H$ be the subspace of $Mat_2(\mathbb{Z})$-invariant functions in $L^2(\Gamma \backslash (PGL_2^+(\mathbb{R}) \times Mat_2(\widehat{\mathbb{Z}))$, $d\nu_0$), and denote by $P$ the orthogonal projection onto $H$. Our first goal is to compute how $P$ acts on $GL_2(\widehat{\mathbb{Z}})$-invariant functions.

Let $F$ be a nonempty finite set of prime numbers. Apply Lemma 2.9(2) to the group $G_F$, the semigroup $S_F$, the set $Y = PGL_2^+(\mathbb{R}) \times Mat_2(\widehat{\mathbb{Z}})$ and the subset $Y_F = PGL_2^+(\mathbb{R}) \times \prod_{p \in F} GL_2(\mathbb{Z}_p) \times \prod_{q \notin F} Mat_2(\mathbb{Z}_q)$ in place of $Y_0$. Note that we can do this because $S_F Y_F$ coincides with $PGL_2^+(\mathbb{R}) \times \prod_{p \in F} Mat_2(\mathbb{Z}_p) \times \prod_{q \notin F} Mat_2(\mathbb{Z}_q)$, which by Corollary 3.6 (or rather its analogue with $\mathbb{H}$ replaced by $PGL_2^+(\mathbb{R})$) is a subset of $Y$ of full measure. Thus, denoting by $P_F$ the projection onto the subspace of $S_F$-invariant functions, for $f_0 \in L^2(\Gamma \backslash (PGL_2^+(\mathbb{R}) \times Mat_2(\widehat{\mathbb{Z}}), d\nu_0)$ we have

$$P_F f_0|_{S_F x} = \zeta_{S_F, \Gamma}(\beta)^{-1} \sum_{s \in \Gamma \backslash S_F / \Gamma} \det(s)^{-\beta} R_\Gamma(s)(T_s f_0)(x) \quad \text{for each } x \in Y_F. \quad (4.3)$$

Given a finite set $J$ of prime numbers which is disjoint from $F$, and a bounded Borel function $f$ on $\Gamma \backslash PGL_2^+(\mathbb{R})$, apply (4.3) to the function $f_0 = f_J$, where $f_J$ is defined by

$$f_J(x) = \begin{cases} f(\tau), & \text{if } x = (\tau, m) \in Y_J, \\ 0, & \text{otherwise.} \end{cases}$$

Then using the operator $T_F$ defined in (4.2), we can write

$$P_F f_J = (T_F f_J).$$

Assume now that $f$ is continuous and compactly supported. By Lemma 4.3 we can find a sequence $\{F_n\}_n$ of finite sets disjoint from $J$ such that $\{T_{F_n} f\}_n$ converges to $\int f d\nu_\infty$ uniformly on compact sets. Hence the sequence $\{P_{F_n} f_J\}_n$ converges weakly in $L^2$ to $\int f d\nu_\infty (1_{\Gamma \backslash PGL_2^+(\mathbb{R}))} j = \int f d\nu_\infty 1_{\Gamma \backslash Y_J}$. Since $PP_F = P$ for every $F$, we get

$$P f_J = \int f d\nu_\infty P 1_{\Gamma \backslash Y_J}.$$ 

Using formula (4.3) for the set $J$ instead of $F$, we also see that $P_J 1_{\Gamma \backslash Y_J}$ is the constant function $\zeta_{S_J, \Gamma}(\beta)^{-1}$. Using again that $PP_J = P$, we therefore obtain

$$P f_J = \zeta_{S_J, \Gamma}(\beta)^{-1} \int_{\Gamma \backslash PGL_2^+(\mathbb{R})} f d\nu_\infty. \quad (4.4)$$

Since the space $H$ contains nonzero constant functions, this in particular implies that

$$\int f_J d\nu = \zeta_{S_J, \Gamma}(\beta)^{-1} \int_{\Gamma \backslash PGL_2^+(\mathbb{R})} f d\nu_\infty,$$

so that $\int f_J d\nu$ is the same for every $\mu$. 

To extend the result to all $GL_2(\hat{\mathbb{Z}})$-invariant functions, fix a finite nonempty set $J$ of prime numbers, and consider a right $\prod_{p \in J} GL_2(\mathbb{Z}_p)$-invariant bounded Borel function $f$ on

$$\Gamma \backslash \left( PGL_2^+(\mathbb{R}) \times \prod_{p \in J} Mat_2(\mathbb{Z}_p) \right).$$

We may consider $f$ as a function on $\Gamma \backslash (PGL_2^+(\mathbb{R}) \times Mat_2(\hat{\mathbb{Z}}))$. Then $f$ is right $GL_2(\hat{\mathbb{Z}})$-invariant, and the space spanned by such functions for all $J$'s is dense in the space of square integrable $GL_2(\hat{\mathbb{Z}})$-invariant functions. Applying again formula (4.3) for the projection $P_J$ (for $J$ in place of $F$), we see that $P_Jf$ is again a function whose value at $(\tau, m) \in PGL_2^+(\mathbb{R}) \times Mat_2(\hat{\mathbb{Z}})$ depends only on $\tau$ and $m_p$ with $p \in J$. The formula also shows that $P_Jf$ is right $GL_2(\hat{\mathbb{Z}})$-invariant. Since $GL_2(\mathbb{Z}_p)$ acts transitively on itself, this shows that the value of $P_Jf$ at $(\tau, m)$ with $m_p \in GL_2(\mathbb{Z}_p)$ for $p \in J$ depends only on $\tau$. In other words, on the space $\Gamma \backslash Y_J$ introduced above, the function $P_Jf$ is a bounded Borel function of the form $\tilde{f}_J$ for some function $\tilde{f}$ on $\Gamma \backslash PGL_2^+(\mathbb{R})$. An important point is that $\tilde{f}$ depends on $f$ but not on $\tilde{\mu}$. By Lemma 2.3(1) and the polarization identity we have

$$\int P_Jf \, d\tilde{\nu} = \int \zeta_{J, \Gamma}(\beta) \int_{\Gamma \backslash Y_J} P_Jf \, d\tilde{\nu} = \int \zeta_{J, \Gamma}(\beta) \int_{\Gamma \backslash Y_J} \tilde{f}_J \, d\tilde{\nu} = \int \int_{\Gamma \backslash PGL_2^+(\mathbb{R})} \tilde{f} \, d\tilde{\nu}_{\infty}.$$  

Since $\int f \, d\tilde{\nu} = \int P_Jf \, d\tilde{\nu}$, we see again that $\int f \, d\tilde{\nu}$ is the same for any $\tilde{\mu}$. It therefore follows that $\int f \, d\tilde{\nu} = \int f \, d\tilde{\nu}_{\beta}$ for any bounded Borel $GL_2(\hat{\mathbb{Z}})$-invariant function on $\Gamma \backslash (PGL_2^+(\mathbb{R}) \times Mat_2(\hat{\mathbb{Z}}))$. Since $\tilde{\nu}$ is $GL_2(\hat{\mathbb{Z}})$-invariant by assumption, we have $\tilde{\nu} = \tilde{\nu}_{\beta}$ and hence $\tilde{\nu} = \tilde{\mu}_{\beta}$.

To prove ergodicity assume $Z_0$ is a left $GL_2^+(\mathbb{Q})$-invariant and right $GL_2(\hat{\mathbb{Z}})$-invariant $\tilde{\mu}_{\beta}$-measurable subset of $PGL_2^+(\mathbb{R}) \times Mat_2(\mathbb{A}_f)$ of positive measure. Since $GL_2^+(\mathbb{Q})(PGL_2^+(\mathbb{R}) \times Mat_2(\hat{\mathbb{Z}})) = PGL_2^+(\mathbb{R}) \times Mat_2(\mathbb{A}_f)$, it follows that the set $Z_0 \cap (PGL_2^+(\mathbb{R}) \times Mat_2(\hat{\mathbb{Z}}))$ has positive measure. Hence $\lambda = \tilde{\mu}_{\beta}(\Gamma \backslash (Z_0 \cap (PGL_2^+(\mathbb{R}) \times Mat_2(\hat{\mathbb{Z}})))) > 0$. It follows that the measure $\tilde{\mu}$ defined by

$$\tilde{\mu}(Z) = \lambda^{-1} \tilde{\mu}_{\beta}(Z_0 \cap Z)$$

is right $GL_2(\hat{\mathbb{Z}})$-invariant and satisfies the conditions in Theorem 4.2. Hence $\tilde{\mu} = \tilde{\mu}_{\beta}$, and consequently the complement of $Z_0$ has $\tilde{\mu}_{\beta}$-measure zero.

We aim to prove that the action of $GL_2^+(\mathbb{Q})$ on $(PGL_2^+(\mathbb{R}) \times Mat_2(\mathbb{A}_f), \tilde{\mu}_{\beta})$ is ergodic. The next step is to consider the action on $Mat_2(\mathbb{A}_f)$ alone.

**Lemma 4.5.** The action of $GL_2^+(\mathbb{Q})$ on $(Mat_2(\mathbb{A}_f), \mu_{\beta})$ is ergodic.

**Proof.** The proof is similar to that of the previous lemma, but requires a much simpler result than Lemma 4.3.

Consider the space $L^2(Mat_2(\hat{\mathbb{Z}}), d\mu_{\beta,f})$ and the subspace $H$ of $Mat_2^+(\mathbb{Z})$-invariant functions. It suffices to show that $H$ consists of constant functions. Denote by $\tilde{P}$ the orthogonal projection onto $H$.

For a finite set $F$ of prime numbers denote by $P_F$ the projection onto the space of $S_F$-invariant functions. Put also

$$Y_F = \prod_{p \in F} GL_2(\mathbb{Z}_p) \times \prod_{q \notin F} Mat_2(\mathbb{Z}_q).$$

Then similarly to (4.3) for any $\Gamma$-invariant function $f \in L^2(Mat_2(\hat{\mathbb{Z}}), d\mu_{\beta,f})$ we have

$$P_Ff|_{S_F \cap \Gamma} = \zeta_{S_F \cap \Gamma}(\beta)^{-1} \sum_{s \in \Gamma \backslash S_F / \Gamma} \det(s)^{-\beta} R_{\Gamma}(s)(T_*f)(m) \text{ for } m \in Y_F. \quad (4.5)$$
This can be either proved similarly to Lemma 2.9(2) or deduced from that lemma by identifying the space of $\Gamma$-invariant functions with the subspace of $L^2(\Gamma \setminus (\text{PGL}_2^+ (\mathbb{R}) \times \text{Mat}_2(\hat{\mathbb{Z}})), d\nu_j)$ of functions depending only on the second coordinate.

For a finite set $J$ of primes disjoint from $F$, and a left $\Gamma$-invariant function $f$ on $\prod_{p \in J} \text{GL}_2(\mathbb{Z}_p)$ define a function $f_J$ by

$$f_J(m) = \begin{cases} f((m_p)_{p \in J}), & \text{if } m_p \in \text{GL}_2(\mathbb{Z}_p) \text{ for } p \in J, \\ 0, & \text{otherwise}. \end{cases}$$

Since $f$ is $\Gamma$-invariant and $\Gamma$ is dense in $\prod_{p \in J} \text{SL}_2(\mathbb{Z}_p)$, $f$ is invariant with respect to multiplication on the left by elements of the latter group. In other words, the value of $f$ at $m$ depends only on $\det(m) \in \prod_{p \in J} \mathbb{Z}_p^*$. Therefore, functions of the form $f(m) = \chi(\det(m))$, where $\chi$ is a character of the compact abelian group $\prod_{p \in J} \mathbb{Z}_p^*$, span a dense subspace of $\Gamma$-invariant functions on $\prod_{p \in J} \text{GL}_2(\mathbb{Z}_p)$.

But if $f = \chi \circ \det$, we have

$$(T_s f)(m) = \chi(\det(m))\chi(\det(s))$$

for $s \in S_F$ and $m \in \prod_{p \in J} \text{GL}_2(\mathbb{Z}_p)$. Applying now (4.5) to the function $f_J$ and using a calculation similar to (3.2) and (3.4), we get

$$P_F f_J |_{S_F m} = \chi(\det((m_p)_{p \in J})) \zeta_{S_F, \Gamma}(\beta)^{-1} \sum_{s \in \Gamma \setminus S_F/\Gamma} \det(s)^{-\beta} R_\Gamma(s) \chi(\det(s))$$

$$= \chi(\det((m_p)_{p \in J})) \prod_{p \in F} \frac{(1 - p^{-\beta})(1 - p^{-\beta + 1})}{(1 - \chi(p)p^{-\beta})(1 - \chi(p)p^{-\beta + 1})}.$$  

If the character $\chi$ is nontrivial, by choosing $F$ large enough the product above can be made arbitrarily small by elementary properties of Dirichlet series (this was used already for the classification of KMS-states of the Bost-Connes system in [3], see also [18]).

On the other hand, if $\chi$ is trivial then $f_J = 1_{Y_J}$. Then applying (4.5) with $J$ in place of $F$ we get $P_J f_J = \zeta_{S_J, \Gamma}(\beta)^{-1}$. In either case we see that $P_J f_J$ is constant.

Let now $f$ be a function on $\prod_{p \in J} \text{GL}_2(\mathbb{Z}_p)$ which is no longer left $\Gamma$-invariant. Since $\Gamma$ is dense in $\text{SL}_2(\hat{\mathbb{Z}})$, any function in $H$ is $\text{SL}_2(\hat{\mathbb{Z}})$-invariant. Hence to compute $P_J f_J$ we can first apply to $f_J$ the projection $Q$ onto the subspace of $\text{SL}_2(\hat{\mathbb{Z}})$-invariant functions. But $Q$ is given by averaging over $\text{SL}_2(\hat{\mathbb{Z}})$-orbits. We then see that $Q f_J = \tilde{f}_J$, where

$$\tilde{f}(m) = \int_{\prod_{p \in J} \text{SL}_2(\mathbb{Z}_p)} f(gm)dg.$$  

Hence $P f_J = P Q f_J = P \tilde{f}_J$ is again a constant function.

To extend the result to all functions on $\text{Mat}_2(\hat{\mathbb{Z}})$, for each $s \in \text{Mat}_2^+(\mathbb{Z})$ we introduce an operator $V_s$ on the space $L^2(\text{Mat}_2(\hat{\mathbb{Z}}), d\mu_{\beta,f})$ by letting $(V_s h)(m) = h(sm)$. Then $V_s P = P$. Using the scaling condition we see that $\det(s)^{-\beta/2} V_s$ is a coisometry with initial space $L^2(s \text{Mat}_2(\hat{\mathbb{Z}}), d\mu_{\beta,f})$. It follows that the adjoint operator is given by

$$(V_s^* h)(y) = \begin{cases} \det(s)^{-\beta} h(s^{-1}y), & \text{if } y \in s \text{Mat}_2(\hat{\mathbb{Z}}), \\ 0, & \text{otherwise}. \end{cases}$$

In particular, we see that if $s \in S_J$ for some finite set $J$ then both operators $V_s$ and $V_s^*$ preserve the space of functions $f$ such that $f(m)$ depends only on $m_p$ with $p \in J$. But then if $f$ is such a function with support on $Y_J$, the function $V_s^* f$ has support on $s Y_J$. Since $V_s P = P$, we have $PV_s^* f = P f$ is a constant. We thus see that the image of a dense space of functions consists of constant functions.
The following simple trick will allow us to combine the two previous lemmas. It expounds a remark in [18].

**Proposition 4.6.** Assume we have mutually commuting actions of locally compact second countable groups $G_1$, $G_2$ and $G_3$ on a Lebesgue space $(X, \mu)$. Suppose that

(i) the actions of $G_1$ on $(X/G_2, \mu)$ and $(X/G_3, \mu)$ are ergodic;

(ii) $G_2$ is connected and $G_3$ is compact totally disconnected.

Then the action of $G_1$ on $(X, \mu)$ is ergodic.

Here by quotient spaces we mean quotients in measure theoretic sense. So by definition

$$L^\infty(X/G_1, \mu) = L^\infty(X, \mu)^{G_1}.$$  

**Proof of Proposition 4.6.** By assumption the action of $G_1 \times G_3$ on $X$ is ergodic. In other words, the action of $G_3$ on $X/G_1$ is ergodic. Since $G_3$ is compact, we can then identify $X/G_1$ with a homogeneous space of $G_3$, say $G_3/H$, where $H$ is a closed subgroup of $G_3$, see e.g. [23, Section 2.1]. Since $G_1 \times G_2$ acts ergodically on $X$, we have an ergodic action of $G_2$ on $X/G_1 = G_3/H$. Since this action commutes with the action of $G_3$ on $G_3/H$ by left translations, it is given by right translations, that is, by a measurable homomorphism $G_2 \to N(H)/H$, where $N(H)$ is the normalizer of $H$ in $G_3$. Such a homomorphism is automatically continuous (see e.g. [23, Theorem B.3]), and since $G_2$ is connected and $N(H)/H$ is totally disconnected, the homomorphism must be trivial. But since the action of $G_2$ is ergodic this means that $H = G_3$, so that $X/G_1$ is a single point. Thus the action of $G_1$ is ergodic.

**Corollary 4.7.** The left action of $GL_2^+(\mathbb{Q})$ on $(PGL_2^+(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f), \bar{\mu}_\beta)$ is ergodic.

**Proof.** The proof is a straightforward application of Proposition 4.6 with $G_1 = GL_2^+(\mathbb{Q})$, $G_2 = PGL_2^+(\mathbb{R})$ and $G_3 = GL_2(\mathbb{Z})$, so that $G_1$ acts on $PGL_2^+(\mathbb{R})$ by multiplication on the left and $G_2$ and $G_3$ act by multiplication on the right on the corresponding factors. That the actions of $G_1$ on the quotient spaces are ergodic is given by Lemma 4.4 and Lemma 4.5.

**Proof of Theorem 4.2.** We follow an argument similar to that of [23, Theorem 25]. Note first that $\bar{\mu}_\beta$ is right $GL(2, \mathbb{Z})$-invariant and satisfies the conditions in Theorem 1.2 by construction. Denote by $K_\beta$ the affine set of measures on $PGL_2^+(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f)$ satisfying the conditions in Theorem 1.2. Let $C_\beta$ be a cone with base $K_\beta$. Denote by $v_0$ its vertex. The cone $C_\beta$ has the structure of a Choquet simplex. Namely, similarly to Proposition 3.6 it can be identified with the set of KMS$\beta$-states on $B^\sim$, where

$$B = C^*_\Gamma(\Gamma\backslash GL_2^+(\mathbb{Q}) \boxtimes \Gamma \times (PGL_2^+(\mathbb{R}) \times \text{Mat}_2(\mathbb{Z}))),$$

$B^\sim$ is obtained from $B$ by adjoining a unit, and $v_0$ corresponds to the state on $B^\sim$ with kernel $B$. Denote by $\bar{\varphi}$ the state corresponding to $\bar{\mu}_\beta$. Then by Remark 2.5 the algebra $\pi_{\bar{\varphi}}(B^\sim)''$ is a reduction of the von Neumann algebra of the orbit equivalence relation defined by the action of $GL_2^+(\mathbb{Q})$ on $(PGL_2^+(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f), \bar{\mu}_\beta)$. By Corollary 1.7 this von Neumann algebra is a factor. Hence $\pi_{\bar{\varphi}}(B^\sim)''$ is also a factor, and therefore $\bar{\mu}_\beta$ is an extremal point of $C_\beta$. The group $GL_2(\mathbb{Z})$ acts on $C_\beta$, and by virtue of Lemma 3.1 the segment $[\bar{\mu}_\beta, v_0]$ is the set of $GL_2(\mathbb{Z})$-invariant points. Suppose now $v \in C_\beta$ is an extremal point. Then $w = \int_{GL_2(\mathbb{Z})} gv dg \in C_\beta$ where each $gv$ is also an extremal point of $C_\beta$. But because of its $GL_2(\mathbb{Z})$ invariance, $w$ lies on $[\bar{\mu}_\beta, v_0]$ and hence is also a convex combination of the extremal points $\bar{\mu}_\beta$ and $v_0$. Since $w$ is the barycenter of a unique probability measure on the set of extremal points, we conclude that either $v = \bar{\mu}_\beta$ or $v = v_0$. Thus $C_\beta = [\bar{\mu}_\beta, v_0]$ and $K_\beta = \{\bar{\mu}_\beta\}$.

This completes the proof of Theorem 4.2.

**Remark 4.8.** We have classified KMS$\beta$-states of the Connes-Marcolli system for $\beta \neq 0, 1$. Let us now briefly discuss the cases $\beta = 0, 1$.

(i) If $\beta = 0$ then by Lemma 3.5 and the considerations following Corollary 3.6 one can conclude that
there are no nonzero finite traces on \( I = C^*_r(\Gamma\backslash \text{GL}^+_2(\mathbb{Q})) \otimes_{\Gamma} (\mathbb{H} \times \text{Mat}_2(\hat{\mathbb{Z}})^\times) \). Therefore the only KMS\(_0\)-states, that is, \( \sigma \)-invariant traces, are those coming from \( A/I = C^*_r(\Gamma\backslash \text{GL}^+_2(\mathbb{Q})) \times_{\Gamma} \mathbb{H} \).

There is a canonical trace defined by the \( \text{GL}^+_2(\mathbb{Q}) \)-invariant measure \( \mu_\infty \) on \( \mathbb{H} \). Notice that though the action of \( \text{GL}^+_2(\mathbb{Q}) \) on \( \mathbb{H} \) is not free and so Proposition \( \ref{prop:free} \) is not immediately applicable, the action of \( \text{GL}^+_2(\mathbb{Q})/\mathbb{Q}^* \) is free in the measure theoretic sense, and this is enough to check the trace property. This is probably the unique such trace.

(ii) If \( \beta = 1 \) then, as we know, KMS\(_1\)-states still correspond to measures satisfying the scaling condition. By the first part of the proof of Corollary \( \ref{cor:KMS} \) and our considerations following that corollary, the set of points \( (\tau, m) \in \mathbb{H} \times \text{Mat}_2(\mathbb{A}_f) \) with \( m_p \neq 0 \) for every \( p \), is a subset of full measure. Such measures indeed exist. Let \( \mu_f' \) be the Haar measure on the locally compact group \( \mathbb{A}_f^2 \) normalized such that \( \mu_f'(\mathbb{Z}^2) = 1 \). We may consider \( \mu_f' \) as a measure on \( \text{Mat}_2(\mathbb{A}_f) \) by identifying \( \mathbb{A}_f^2 \) with the set of matrices with zero first column. Then \( \mu_f = 2\mu_\infty \times \mu_f' \) is a measure with the required properties. Using the action of \( \text{GL}_2(\mathbb{Z}) \) by multiplication on the right we can then construct infinitely many such measures (notice that the stabilizer of \( \mu' \) in \( \text{GL}_2(\mathbb{Z}) \) is the group of upper triangular matrices). We conjecture that this way one gets all extremal KMS\(_1\)-states.

**Remark 4.9.** Let \( 1 < \beta \leq 2 \), and denote by \( \varphi_\beta \) the unique KMS\(_\beta\)-state on the Connes-Marcolli C*-algebra \( A \). It is easy to describe the flow of weights of the factor \( \pi_{\varphi_\beta}(A)' \). Let us first consider the algebra \( B = C^*_r(\Gamma\backslash \text{GL}^+_2(\mathbb{Q})) \otimes_{\Gamma} (\text{PGL}^+_2(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f)) \) and the state \( \varphi_\beta \) on \( B \) corresponding to \( \mu_\beta \), and describe the flow of weights of \( \pi_{\varphi_\beta}(B)' \). By Remark \( \ref{rem:free} \) equivalently we want to describe the flow of weights of the orbit equivalence relation defined by the ergodic action of \( \text{GL}^+_2(\mathbb{Q}) \) on \( (\text{PGL}^+_2(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f), \mu_\beta) \).

The group \( \mathbb{R}_+^* \) acts on the measure space \( (\mathbb{R}_+^* \times \text{PGL}^+_2(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f), \lambda \times \mu_\infty \times \mu_\beta) \), where \( \lambda \) is a measure in the Lebesgue measure class, by

\[
(t(s, h, \rho) = (t^{-1/\beta} s, h, \rho).
\]

The flow of weights is induced by this action on the quotient of the space by the action of \( \text{GL}^+_2(\mathbb{Q}) \) defined by

\[
g(s, h, \rho) = (\det(g)s, gh, g\rho).
\]

We have an isomorphism \( \text{GL}^+_2(\mathbb{R})/\{\pm 1\} \to \mathbb{R}_+^* \times \text{PGL}^+_2(\mathbb{R}), g \mapsto (\det(g), \bar{g}) \), where \( \bar{g} \) denotes the class of \( g \) in \( \text{PGL}^+_2(\mathbb{R}) \). So instead of the space \( \mathbb{R}_+^* \times \text{PGL}^+_2(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f) \) we may consider \( (\text{GL}^+_2(\mathbb{R})/\{\pm 1\}) \times \text{Mat}_2(\mathbb{A}_f) \). We may further replace \( \text{GL}^+_2(\mathbb{R}) \) by \( \text{GL}_2(\mathbb{R}) \), but instead of the action of \( \text{GL}^+_2(\mathbb{Q}) \) we then have to consider the action of \( \text{GL}_2(\mathbb{Q}) \). Finally, replace \( \text{GL}_2(\mathbb{R}) \) by \( \text{Mat}_2(\mathbb{R}) \), and so instead of \( \text{GL}_2(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f) \) consider \( \text{Mat}_2(\mathbb{A}_f), \) where \( \mathbb{A}_f = \mathbb{R} \times \mathbb{A}_f \) is the full adele space. To summarize, \( \mathbb{R}_+^* \) acts on \( \text{Mat}_2(\mathbb{A}_f) = \text{Mat}_2(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f) \) by \( t(m, \rho) = (t^{-1/\beta} m, \rho) \), and the flow of weights of the factor \( \pi_{\varphi_\beta}(B)' \) is induced by this action on the quotient of the measure space \( (\text{Mat}_2(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f), \lambda_\infty \times \mu_\beta) \), where \( \lambda_\infty \) is the usual Lebesgue measure on \( \text{Mat}_2(\mathbb{R}) \cong \mathbb{R}^4 \), by the action of \( \text{GL}_2(\mathbb{Q}) \times \{\pm 1\} \) defined by \( (g, s)(m, \rho) = (gms, gp) \).

Denote the measure \( \lambda_\infty \times \mu_\beta \) on \( \text{Mat}_2(\mathbb{A}_f) \) by \( \lambda_\beta \). Note that \( \lambda_\beta \) is a Haar measure on the additive group \( \text{Mat}_2(\mathbb{A}_f) \).

Similarly, by identifying \( \mathbb{R}_+^* \times \mathbb{R}^4 \) with \( \text{GL}^+_2(\mathbb{R})/\text{SO}_2(\mathbb{R}) \) we conclude that the flow of weights of the factor \( \pi_{\varphi_\beta}(A)' \) is defined on the quotient of the measure space \( (\text{Mat}_2(\mathbb{A}_f), \lambda_\beta) \) by the action of \( \text{GL}_2(\mathbb{Q}) \times \text{SO}_2(\mathbb{R}) \) defined by \( (g, s)(m, \rho) = (gms, gp) \) for \( (g, s) \in \text{GL}_2(\mathbb{Q}) \times \text{SO}_2(\mathbb{R}) \) and \( (m, \rho) \in \text{Mat}_2(\mathbb{A}_f) = \text{Mat}_2(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f) \).

It seems natural to conjecture that the action of \( \text{GL}_2(\mathbb{Q}) \) on \( (\text{Mat}_2(\mathbb{A}_f), \lambda_\beta) \) is ergodic, so the flows of weights of the factors \( \pi_{\varphi_\beta}(A)' \) and \( \pi_{\varphi_\beta}(B)' \) are trivial, and thus the factors are of type III1. The analogous property in the one-dimensional case indeed holds \( \mathbb{R} \) \( \mathbb{I} \). Note that so far we have only shown that the action of \( \text{GL}_2(\mathbb{Q}) \times \mathbb{R}^4 \) is ergodic, which is equivalent to ergodicity of the action of \( \text{GL}^+_2(\mathbb{Q}) \) on \( (\text{PGL}^+_2(\mathbb{R}) \times \text{Mat}_2(\mathbb{A}_f), \bar{\mu}_\beta) \). Note also that similarly to the one-dimensional
case \([2]\), by virtue of Lemma \([15,16]\) and Proposition \([16,19]\) to prove the conjecture it would be enough to show that the action of \(\text{GL}^+_2(\mathbb{Q})\) on \(\text{Mat}_2(\mathbb{A}_f)/\text{GL}_2(\hat{\mathbb{Z}})\) is ergodic, or equivalently, the action of \(\text{GL}_2(\mathbb{Q})\) on \((\text{Mat}_2(\mathbb{A})/\text{GL}_2(\hat{\mathbb{Z}}), \lambda_\beta)\) is ergodic. Recall that in the one-dimensional case the corresponding ergodicity result for the action of \(\mathbb{Q}^*\) on \(\mathbb{A}/\hat{\mathbb{Z}}^*\) was established in \([1]\) and \([2]\).

Remark 4.10. We believe that the results of Sections \([3,4]\) and \([1]\) are valid for \(\text{GL}_n\) for any \(n \geq 2\). More precisely, consider the algebra \(C^*_r(\text{SL}_n(\mathbb{Z})\backslash \text{GL}^+_n(\mathbb{Q}) \times \text{St}_n(\mathbb{Z}) \times \text{Mat}_n(\hat{\mathbb{Z}}))\). Define a dynamics by the homomorphism \(\text{GL}^+_n(\mathbb{Q}) \ni g \mapsto \det(g)\). Then

(i) \(\beta \in (-\infty, 0) \cup (0, 1) \cup \cdots \cup (n-2, n-1)\) there are no KMS-\(\beta\)-states;

(ii) \(\beta \in (n-1, n]\) there exists a unique KMS-\(\beta\)-state;

(iii) \(\beta > n\) there is a one-to-one correspondence between KMS-\(\beta\)-states and probability measures on \(\text{SL}_n(\mathbb{Z})\backslash \text{PGL}^+_n(\mathbb{R}) \times \text{GL}_n(\hat{\mathbb{Z}})\);

(iv) \(\beta = 0, 1, \ldots, n-1\) there is a KMS-\(\beta\)-state defined by the Haar measure on \(\mathbb{A}_f^{\beta n}\), when we identify the latter group with the set of matrices in \(\text{Mat}_n(\mathbb{A}_f)\) with zero first \(n-\beta\) columns.

The key step for this generalization would be an analogue of Lemma \([5,9]\).
