Abstract Recent work highlighting an anomaly in the modelling of rotary electromagnetic stirring (EMS) in the continuous casting of round steel billets is extended to the case of longitudinal stirring for rectangular blooms. An earlier, still often-cited, model forms the basis of the current analysis, which uses asymptotic methods on the three-dimensional (3D) Maxwell equations and demonstrates how the earlier result for the components of the Lorentz force is but a particular case of a more general form. Time-dependent 3D computations using finite-element methods are also performed to verify the validity of the asymptotic analysis, and the relevance of the results to modulated EMS is noted.

Keywords Asymptotic analysis · Continuous casting · Electromagnetic stirring

1 Introduction

Electromagnetic stirring (EMS) has been used in the continuous casting of steel [1] since as early as the 1970s as a way to control solidification structures, thereby increasing yield and productivity. In tandem, mathematical modelling has played an important role in the implementation of EMS, as regards providing understanding of exactly what effect stirring has.

A series of papers by Schwerdtfeger et al. [2–7] which explored, both experimentally and theoretically, the effect of stirring in the round-billet, rectangular-bloom and slab geometries that are characteristic for the continuous casting of steel, have formed the cornerstone of the modelling literature in this area. These models consist of the Navier–Stokes equations for the velocity field of the molten metal and Maxwell’s equations for the induced magnetic flux density; in principle, these are two-way coupled, since the alternating magnetic field gives rise to a Lorentz force which drives the velocity field, which in turn affect the magnetic field. Moreover, the frequency of the magnetic field is typically great enough to allow the use of the time average of the Lorentz force as input to the Navier–Stokes equations.
However, recent work by Vynnycky [8] revisited the problem of rotary EMS applied to round-billet continuous casting and found that the method used originally in [2,7] to determine the components of the Lorentz force led to a non-unique solution; this was a consequence of the fact that the normal component of the induced magnetic flux density, rather than the tangential ones, was prescribed as the boundary condition. Moreover, since the normal component was prescribed in models for the case of longitudinal stirring for rectangular blooms also [3–6], it is natural to expect non-uniqueness in those models too. Furthermore, since the expressions for the components of the Lorentz force given in [3–6] are still frequently used [9–17], it is clear that a resolution of the issue is still timely, especially in view of modern-day interest in modulated EMS [18–20]. In this case, magnetic fields of different frequencies are applied and it is the intention that the resulting Lorentz force should have a constant time-averaged part and a time-varying one; it goes without saying that posing the correct boundary conditions for the magnetic field is vital for obtaining meaningful results from modelling.

Furthermore, although this paper revisits an earlier EMS model in a similar spirit to [8], the details turn out to be more extensive, but also more subtle. In the case of rotary EMS applied to round-billet continuous casting, the geometry is axisymmetric and considerable progress can be made analytically. In the current paper, on the other hand, the geometry is genuinely three-dimensional (3D), and analytical progress via the use of asymptotic methods can only be made because we identify a suitable asymptotically small parameter in which we can conduct the analysis. In addition, we find that the form of the boundary condition that is responsible for stirring influences the form of the asymptotic expansion that is needed. Last, but certainly by no means least, we verify the accuracy of the analysis by comparison with results from 3D computations.

The structure of the paper is as follows. In Sect. 2, we formulate the problem mathematically, and in Sect. 3 we non-dimensionalize the governing equations. The main body of the analysis, in terms of an asymptotically small parameter, is given in Sect. 4, whereas Sect. 5 outlines the numerical method used to solve the fully 3D transient problem. Results are given in Sect. 6, and conclusions are drawn in Sect. 7.

2 Model equations

2.1 Governing equations

We consider, as shown in Fig. 1, a linear travelling stirrer situated at \( y = 0 \), \(-h/2 \leq z \leq h/2\), \( 0 \leq x \leq l \), operating on a molten steel region with cross-section \( 0 \leq y \leq b \), \(-h/2 \leq z \leq h/2\), as shown in Fig. 2. For simplicity, we neglect unnecessary details such as the existence of a solidified shell around the rim of the cross-section, the presence of a mould wall on the other three sides of the steel, as would occur in mould electromagnetic stirring (M-EMS) or an air gap between the solidified shell and the stirrer, as could occur in M-EMS or strand electromagnetic stirring (S-EMS); instead, the initial focus is on formulating the simplest well-posed problem. Moreover, as suggested by Fig. 2, this constitutes having to consider the air surrounding the other three sides of the principal region of interest.

As already motivated in the introduction, we consider the solution of Maxwell’s equations in the magnetohydrodynamic (MHD) approximation, which consist of:

- the magnetic field constraint,
  \[
  \nabla \cdot \mathbf{B} = 0,
  \tag{2.1}
  \]
  where \( \mathbf{B} \) is the magnetic flux density vector;

- Ampere’s law,
  \[
  \mathbf{J} = \nabla \times \mathbf{H},
  \tag{2.2}
  \]
  where \( \mathbf{H} \) is the magnetic field strength, which is related to \( \mathbf{B} \) by \( \mathbf{B} = \eta \mathbf{H} \), where \( \eta \) is the magnetic permeability, and \( \mathbf{J} \) is the electrical current density vector;
Fig. 1 Schematic of the arrangement for the longitudinal stirring of blooms and billets. The figure is not drawn to scale; typically, $b$ and $h$ are more or less equal, and $l$ is around four times larger.

- Faraday’s law,

$$\nabla \times \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t}, \quad (2.3)$$

where $t$ is time and $\mathbf{E}$ is the electric field;

- Ohm’s law,

$$\mathbf{J} = \sigma (\mathbf{E} + \mathbf{v} \times \mathbf{B}), \quad (2.4)$$

where $\sigma$ is the electrical conductivity of the medium in question, which we take to be constant, and is $\mathbf{v}$ the velocity vector, which we will simply set to zero.

Manipulating (2.2)–(2.4), we arrive at

$$\sigma \eta \frac{\partial \mathbf{B}}{\partial t} = \nabla^2 \mathbf{B}, \quad (2.5)$$
note, however, that this must still be solved together with Eq. (2.1). In more detail, and with $B_x$, $B_y$ and $B_z$ as $x$-, $y$- and $z$-components, respectively, of $B$, we have

$$\frac{\partial B_x}{\partial x} + \frac{\partial B_y}{\partial y} + \frac{\partial B_z}{\partial z} = 0,$$

(2.6)

$$\sigma \frac{\partial B_k}{\partial t} = \frac{\partial^2 B_k}{\partial x^2} + \frac{\partial^2 B_k}{\partial y^2} + \frac{\partial^2 B_k}{\partial z^2}, \quad k = x, y, z.$$

(2.7)

Key quantities which can be calculated after $B_x$, $B_y$ and $B_z$ have been computed are the components of the Lorentz force, $F_x$, $F_y$ and $F_z$, which are given by

$$F_x = J_y B_z - J_z B_y, \quad F_y = J_z B_x - J_x B_z, \quad F_z = J_x B_y - J_y B_x,$$

(2.8)

where $(J_x, J_y, J_z)$ are the components of $J$, and are given by

$$J_x = \frac{1}{\eta} \left( \frac{\partial B_z}{\partial y} - \frac{\partial B_y}{\partial z} \right), \quad J_y = \frac{1}{\eta} \left( \frac{\partial B_x}{\partial z} - \frac{\delta}{\delta x} \frac{\partial B_z}{\partial x} \right), \quad J_z = \frac{1}{\eta} \left( \frac{\delta}{\delta x} \frac{\partial B_y}{\partial y} - \frac{\delta}{\delta y} \frac{\partial B_x}{\partial y} \right).$$

(2.9)

In addition, $F_x$, $F_y$ and $F_z$ are used to calculate the time-averaged components of the Lorentz force—$\bar{F}_x$, $\bar{F}_y$ and $\bar{F}_z$—via

$$\bar{F}_x = \frac{1}{2\pi/\omega} \int_0^{2\pi/\omega} F_x \, dt', \quad \bar{F}_y = \frac{1}{2\pi/\omega} \int_0^{2\pi/\omega} F_y \, dt', \quad \bar{F}_z = \frac{1}{2\pi/\omega} \int_0^{2\pi/\omega} F_z \, dt',$$

where the integrals are taken with respect to time over one oscillation period, $2\pi/\omega$, with $\omega$ as the angular frequency of the current, which is related to the frequency of the current, $f$, by $\omega = 2\pi f$.

2.2 Boundary and interfacial conditions

One of the key points of this paper concerns what should be the boundary condition at $y = 0$, $|z| \leq h/2$ which is in effect responsible for the Lorentz force. Dubke et al. [3] prescribe $B_y$ at $-h/2 \leq z \leq h/2$, $y = 0$, and their
results, based on this condition, have been in use ever since; their approach is recapped in Appendix A. In this sense, prescribing the normal component of the magnetic field is consistent with earlier work for rotary EMS acting on a round billet [2,7]. However, Vynnycky [8] recently re-analyzed the same problem and found that prescribing the normal component would lead to a non-unique solution for the components of magnetic flux density vector; on the other hand, prescribing the tangential components would lead to a unique solution. This observation, for a round billet, suggests that applying a boundary condition on the normal component for a rectangular bloom or billet will lead to a non-unique solution also. In turn, this suggests instead that one should prescribe the tangential components of \( \mathbf{B} \), and we will therefore set at \( y = 0 \),

\[
B_x = \begin{cases} 
\alpha (z) \cos (\omega t - \lambda x) & \text{for } |z| \leq h/2, \\
0 & \text{for } |z| > h/2,
\end{cases} \tag{2.10}
\]

\[
B_z = \begin{cases} 
\beta (z) \cos (\omega t - \lambda x) & \text{for } |z| \leq h/2, \\
0 & \text{for } |z| > h/2,
\end{cases} \tag{2.11}
\]

where \( \lambda \) is the wave vector given by \( \lambda = \pi / p \), with \( p \) as the pole pitch, i.e. the distance from north to south pole in the inductor. The motivation for choosing the forms given in (2.10) and (2.11) is that they constitute a travelling wave in the \( x \)-direction, as was also considered in [3], and also give the most general possible dependence in the \( z \)-direction; as a result, we are able later on to relate the Lorentz force directly to what is chosen for \( \alpha (z) \) and \( \beta (z) \), as shown in Sect. 4.1.2.

As regards the interfaces between air and steel at \( y = b, |z| \leq h/2 \) and \( |z| = h/2, 0 \leq y \leq b \), we apply the usual electromagnetic interface conditions. These are the continuity of the tangential components of the magnetic field strength and the normal component of the magnetic flux density, which are written as

\[
\left[ \frac{\mathbf{B} \cdot \mathbf{t}}{\eta} \right]^+ = 0, \quad \left[ \mathbf{B} \cdot \mathbf{n} \right]^+ = 0, \tag{2.12}
\]

respectively, where \( \mathbf{t} \) is the unit tangential vector and \( \mathbf{n} \) is the unit normal vector at these interfaces, and the continuity of the tangential components of the electric field, which is written as

\[
[\mathbf{E} \cdot \mathbf{t}]^+ = 0. \tag{2.13}
\]

In (2.12) and (2.13), \([ \cdot ]^+\) denotes the difference in the value of a function in the air \((+\)) and in the steel \((-\)).

In the air far from the steel, we should also expect

\[
\mathbf{B} \to 0 \quad \text{as } r \to \infty, \tag{2.14}
\]

where \( r = \sqrt{x^2 + y^2 + z^2} \).

3 Non-dimensionalization

It is ultimately more instructive to non-dimensionalize the equations, and we do this through

\[
X = \frac{x}{l}, \quad Y = \frac{y}{b}, \quad Z = \frac{z}{b}, \quad \tau = \frac{\omega t}{2\pi}, \tag{3.1}
\]

and, for \( k = x, y, z \) and \( K = X, Y, Z \),

\[
B_K = \frac{B_k}{B_0}, \quad E_K = \frac{E_k}{B_0/\sigma_s \eta_s b}, \quad F_K = \frac{F_k}{B_0^2/\eta_s b}, \quad J_K = \frac{J_k}{B_0/\eta_s b}, \tag{3.2}
\]

where \( B_0 \) is the characteristic magnetic flux density, and \( \eta_s \) and \( \sigma_s \) are the steel magnetic permeability and electrical conductivity, respectively; note also that the corresponding quantities for air, \( \eta_a \) and \( \sigma_a \), will also be required later on. Now, for \( 0 \leq X \leq 1, 0 \leq Y \leq 1, -H/2 \leq Z \leq H/2 \), where \( H = h/b \), Eqs. (2.6) and (2.7) give

\[
\frac{\partial B_X}{\partial X} + \frac{\partial B_Y}{\partial Y} + \frac{\partial B_Z}{\partial Z} = 0, \tag{3.3}
\]
\[
\Omega \frac{\partial B_k}{\partial \tau} = \delta \frac{\partial^2 B_k}{\partial X^2} + \frac{\partial^2 B_k}{\partial Y^2} + \frac{\partial^2 B_k}{\partial Z^2}, \quad k = X, Y, Z, 
\]  
(3.4)

where \( \delta = b/l \) and \( \Omega = f \sigma \eta b^2 \); however, note that the values for \( \Omega \) for steel, \( \Omega_s \), and air, \( \Omega_a \), are different, but can be calculated from the data in Table 1. Also, for later use, note that
\[
J_X = \frac{\partial BZ}{\partial Y} - \frac{\partial BY}{\partial Z}, \quad J_Y = \frac{\partial BX}{\partial Z} - \delta \frac{\partial BZ}{\partial X}, \quad J_Z = \delta \frac{\partial BY}{\partial X} - \frac{\partial BX}{\partial Y},
\]  
(3.5)

and
\[
F_X = J_Y BZ - J_Z BY, \quad F_Y = J_Z BX - J_X BZ, \quad F_Z = J_X BY - J_Y BX.
\]  
(3.6)

The boundary conditions (2.10)–(2.14) are then: at \( Y = 0 \),
\[
B_X = \begin{cases} 
\tilde{\alpha}(Z) \cos (2\pi \tau - \Lambda X) & \text{for } |Z| \leq H/2, \\
0 & \text{for } |Z| > H/2,
\end{cases}
\]  
(3.7)

\[
B_Z = \begin{cases} 
\tilde{\beta}(Z) \cos (2\pi \tau - \Lambda X) & \text{for } |Z| \leq H/2, \\
0 & \text{for } |Z| > H/2,
\end{cases}
\]  
(3.8)

where \( \Lambda = \lambda l \) and
\[
\tilde{\alpha} = \frac{\alpha}{[\alpha]}, \quad \tilde{\beta} = \frac{\beta}{[\beta]},
\]

with \([\alpha]\) and \([\beta]\) denoting the scales for \( \alpha \) and \( \beta \), respectively; at \( Y = 1, |Z| \leq H/2 \) and \( |Z| = H/2, 0 \leq Y \leq 1, \)
\[
\begin{bmatrix} \mathbf{B} \cdot \mathbf{t} \end{bmatrix}^+_{\eta} = 0, \quad [\mathbf{B} \cdot \mathbf{n}]^+ = 0, \quad [\mathbf{E} \cdot \mathbf{t}]^- = 0;
\]  
(3.9)

as \( R \to \infty \), where \( R = \sqrt{X^2 + Y^2 + Z^2} \),
\[
\mathbf{B} \to 0.
\]  
(3.10)

4 Analysis

Since \( \delta \sim 1/4 \), it is perhaps tempting to consider \( \delta \ll 1 \) straightaway and to pose regular perturbation expansions for \( B_X, B_Y \) and \( B_Z \) with \( \delta \) as the expansion parameter, as would be suggested by Eqs. (3.3) and (3.4). However, the

| Parameter                  | Symbol | Value |
|----------------------------|--------|-------|
| Steel width                | \( b \) | 0.25 m |
| Characteristic magnetic flux density | \( B_0 \) | 0.02 T |
| Current frequency          | \( f \) | 50 Hz |
| Steel breadth              | \( h \) | 0.35 m |
| Stirrer length             | \( l \) | 1.2 m |
| Inductor pole pitch        | \( p \) | 0.06 m |
| Air magnetic permeability  | \( \eta_a \) | \( 1.2566 \times 10^{-6} \) V s A\(^{-1}\) m\(^{-1}\) |
| Steel magnetic permeability| \( \eta_s \) | \( 1.2566 \times 10^{-6} \) V s A\(^{-1}\) m\(^{-1}\) |
| Air electrical conductivity| \( \sigma_a \) | \( 3 \times 10^{-15} \cdot 8 \times 10^{-15} \) A V\(^{-1}\) m\(^{-1}\) |
| Steel electrical conductivity| \( \sigma_s \) | \( 7.14 \times 10^5 \) A V\(^{-1}\) m\(^{-1}\) |
character of the problem turns out to be different to this. First of all, Eq. (3.3) and the boundary conditions in (3.7) imply that the solutions for \( B_X, B_Y \) and \( B_Z \) will be of the form

\[
B_X, B_Y, B_Z \sim \begin{cases} 
\cos(2\pi \tau - \Lambda X), \\
\sin(2\pi \tau - \Lambda X).
\end{cases}
\]

Thus, in (3.3), the first term will now be of order \( O(\lambda b) \); we see from Table 1 that this non-dimensional quantity is no longer necessarily small (\( \lambda b \approx 13.1 \)) and that it does not even contain the length of the stirrer. In addition, the apparently \( O(\delta^2) \) terms in (3.4) are actually \( O(\lambda^2 b^2) \). Thus, to proceed more appropriately, we will first set

\[
B_k = \text{Re} \left( \mathcal{B}_k (Y, Z) e^{i(2\pi \tau - \Lambda X)} \right), \quad E_k = \text{Re} \left( \mathcal{E}_k (Y, Z) e^{i(2\pi \tau - \Lambda X)} \right), \quad k = X, Y, Z,
\]

where \( \text{Re} \) denotes the real part of a complex number and \( i = \sqrt{-1} \). Equations (3.3) and (3.4) become

\[
- \Delta \mathcal{B}_X + \frac{\partial \mathcal{B}_Y}{\partial Y} + \frac{\partial \mathcal{B}_Z}{\partial Z} = 0, \tag{4.1}
\]

\[
\left( 2\pi i + \Delta^2 \right) \mathcal{B}_k = \frac{\partial^2 \mathcal{B}_k}{\partial Y^2} + \frac{\partial^2 \mathcal{B}_k}{\partial Z^2}, \quad k = X, Y, Z, \tag{4.2}
\]

where \( \Delta = \lambda b \). In terms of \( \mathcal{B}_X, \mathcal{B}_Y \) and \( \mathcal{B}_Z \), the boundary conditions are now: at \( Y = 0 \),

\[
\mathcal{B}_X = \begin{cases} 
\tilde{\alpha}(Z) & \text{for } |Z| \leq H/2, \\
0 & \text{for } |Z| > H/2,
\end{cases} \tag{4.3}
\]

\[
\mathcal{B}_Z = \begin{cases} 
\tilde{\beta}(Z) & \text{for } |Z| \leq H/2, \\
0 & \text{for } |Z| > H/2
\end{cases} \tag{4.4}
\]

at \( Y = 1, \ |Z| \leq H/2 \) and \( |Z| = H/2, 0 \leq Y \leq 1, \)

\[
\left[ \frac{\mathcal{B} \cdot n}{\eta} \right]^+ = 0, \quad [\mathcal{B} \cdot n]^- = 0, \quad [E \cdot t]^+ = 0, \tag{4.5}
\]

with \( \mathcal{B} = (\mathcal{B}_X, \mathcal{B}_Y, \mathcal{B}_Z) \) and \( \mathcal{E} = (\mathcal{E}_X, \mathcal{E}_Y, \mathcal{E}_Z) \); as \( R \to \infty, \)

\( \mathcal{B} \to 0. \)

We can note at this point that it is inconvenient to have an interface condition, (4.5), in terms of \( \mathcal{E} \) when the rest of the problem is posed in terms of \( \mathcal{B} \). We will therefore write out the equations in (4.5) in their full forms in terms of \( \mathcal{B}_X, \mathcal{B}_Y \) and \( \mathcal{B}_Z \), which gives: at \( Y = 1, |Z| = H/2, \)

\[
\left[ \frac{\mathcal{B}_X}{\eta} \right]^+ = 0, \quad [\mathcal{B}_Y]^- = 0, \quad [\mathcal{B}_Z]^- = 0, \tag{4.7}
\]

\[
\left[ \frac{1}{\sigma \eta} \left( \frac{\partial \mathcal{B}_Z}{\partial Y} - \frac{\partial \mathcal{B}_Y}{\partial Z} \right) \right]^+ = 0, \quad \left[ \frac{1}{\sigma \eta} \left( -i \Delta \mathcal{B}_Z - \frac{\partial \mathcal{B}_X}{\partial Z} \right) \right]^+_\varepsilon = 0; \tag{4.8}
\]

at \( |Z| = H/2, 0 \leq Y \leq 1, \)

\[
\left[ \frac{\mathcal{B}_X}{\eta} \right]^+ = 0, \quad [\mathcal{B}_Y]^- = 0, \quad [\mathcal{B}_Z]^- = 0, \tag{4.9}
\]

\[
\left[ \frac{1}{\sigma \eta} \left( \frac{\partial \mathcal{B}_Z}{\partial Y} - \frac{\partial \mathcal{B}_Y}{\partial Z} \right) \right]^+_\varepsilon = 0, \quad \left[ \frac{1}{\sigma \eta} \left( -i \Delta \mathcal{B}_Y - \frac{\partial \mathcal{B}_X}{\partial Y} \right) \right]^- = 0. \tag{4.10}
\]

Now, in the absence of any further simplification for general values of \( \Delta \)—other than \( \Delta \ll 1 \), which appears to be not of technological interest anyway—it would be necessary to resort to a numerical solution. Interestingly,
however, it appears to be simpler to solve (3.3) and (3.4), subject to (3.7)–(3.10), numerically than it is to solve (4.1)–(4.6) numerically, even though the latter is a two-dimensional steady state system of equations, whereas the former is three-dimensional and transient. By “simpler”, we mean that there exists commercial software such as the finite element-based Comsol Multiphysics which we will use later anyway, with readily available modules to solve the former, but not the latter, with the main difficulty being the implementation of the interface conditions that arise out of (4.5), i.e. (4.8) and (4.10).

Thus, instead of trying to solve (4.1)–(4.4) and (4.6)–(4.10) numerically, we will first consider these equations analytically for the case $\Delta \gg 1$, which is indeed the regime pertinent to the data in Table 1. Note also that, although the data given are the same as those used in [3], it is quite typical for most casting machines that apply longitudinal EMS; the only significant difference would be that the steel breadth is as small as the width, but this does not affect the value of $\Delta$, which does not depend on the breadth anyway.

4.1 $\Delta \gg 1$

In this subsection, we first determine the solutions for $B_X, B_Y$ and $B_Z$; thereafter, these are used to constitute expressions for $J_X, J_Y, J_Z, F_X, F_Y$ and $F_Z$.

4.1.1 $B_X, B_Y, B_Z$

Setting $\varepsilon = 1/\Delta$, where $\varepsilon \ll 1$, Eqs. (4.1) and (4.2) become

$$i B_X = \varepsilon \left( \frac{\partial B_Y}{\partial Y} + \frac{\partial B_Z}{\partial Z} \right),$$

$$\left( 2\pi \Omega \varepsilon^2 i + 1 \right) \mathcal{B}_k = \varepsilon^2 \left( \frac{\partial^2 \mathcal{B}_k}{\partial Y^2} + \frac{\partial^2 \mathcal{B}_k}{\partial Z^2} \right), \quad k = X, Y, Z,$$

respectively. These suggest that, at leading order in $\varepsilon$, $\mathcal{B}_X, \mathcal{B}_Y, \mathcal{B}_Z \approx 0$, which would clearly contradict (4.3) and (4.4) for $|Z| < H/2$. Thus, since a small parameter multiplies the highest order derivatives in Eqs. (4.11) and (4.12), there must be boundary layers in the problem. The most obvious location for these is at $Y = 0$ for $|Z| < H/2$. Anticipating that $Y \sim \varepsilon$, we set $Y = \varepsilon \tilde{Y}$, upon which (4.11) and (4.12) become

$$i \mathcal{B}_X = \frac{\partial B_Y}{\partial \tilde{Y}} + \varepsilon \frac{\partial B_Z}{\partial Z},$$

$$\left( 2\pi \Omega_s \varepsilon^2 i + 1 \right) \mathcal{B}_k = \frac{\partial^2 \mathcal{B}_k}{\partial \tilde{Y}^2} + \varepsilon^2 \frac{\partial^2 \mathcal{B}_k}{\partial Z^2}, \quad k = X, Y, Z,$$

respectively. Note that we have replaced $\Omega$ in (4.12) by $\Omega_s$, since the analysis to follow concerns the steel region. Observe also that we retain $\Omega_s$ as a dimensionless $O(1)$ parameter since, on using the values in Table 1, $\Omega_s \approx 2.8$.

Setting

$$B_k = B_k^{(0)} + \varepsilon B_k^{(1)} + O(\varepsilon^2)$$

$$\mathcal{B}_k = \mathcal{B}_k^{(0)} + \varepsilon \mathcal{B}_k^{(1)} + O(\varepsilon^2), \quad k = X, Y, Z,$$

we have, at $O(\varepsilon^0)$,

$$i \mathcal{B}_X^{(0)} = \frac{\partial B_Y^{(0)}}{\partial \tilde{Y}},$$
\[
\mathcal{B}_k = \frac{\partial^2 \mathcal{B}_k}{\partial \tilde{Y}^2}, \quad k = X, Y, Z, 
\]
(4.18)

with the boundary conditions being (4.3) and (4.4), and

\[
\mathcal{B}_X^{(0)}, \mathcal{B}_Y^{(0)}, \mathcal{B}_Z^{(0)} \rightarrow 0 \quad \text{as} \ \tilde{Y} \rightarrow \infty,
\]
(4.19)

which must come from matching to the solutions in (4.13), taken at leading order. So,

\[
\mathcal{B}_X^{(0)} = \tilde{\alpha}(Z) e^{-\tilde{Y}},
\]
(4.20)

\[
\mathcal{B}_Y^{(0)} = -i \tilde{\alpha}(Z) e^{-\tilde{Y}},
\]
(4.21)

\[
\mathcal{B}_Z^{(0)} = \tilde{\beta}(Z) e^{-\tilde{Y}}.
\]
(4.22)

Note here that \( \mathcal{B}_X^{(0)} \) and \( \mathcal{B}_Z^{(0)} \) may be solved for first, with the solution for \( \mathcal{B}_X^{(0)} \) then being used in (4.17); integrating this and applying (4.19) gives the expression for \( \mathcal{B}_Y^{(0)} \), which then clearly satisfies (4.18) for \( k = Y \), indicating self-consistency. We can also observe that (4.20)–(4.22) will not satisfy (4.9)–(4.10), for which boundary layers where \( |H/2 \pm Z| \sim \varepsilon \) are required; we omit the details of the analysis for those, as they are of little importance for the main results that follow, although we do return to a discussion of these in Sect. 6.1.

For later use, we need the second and third terms, i.e. at \( \varepsilon^1 \) and \( \varepsilon^2 \), in the expansions also. At \( \varepsilon^1 \), we have

\[
i \mathcal{B}_X^{(1)} = \frac{\partial \mathcal{B}_Y^{(1)}}{\partial \tilde{Y}} + \frac{\partial \mathcal{B}_Z^{(0)}}{\partial Z},
\]
(4.23)

\[
i \mathcal{B}_k^{(1)} = \frac{\partial^2 \mathcal{B}_k^{(1)}}{\partial \tilde{Y}^2}, \quad k = X, Y, Z,
\]
(4.24)

subject to

\[
\mathcal{B}_X^{(1)} = 0, \quad \mathcal{B}_Z^{(1)} = 0, \quad \text{at} \ \tilde{Y} = 0,
\]
(4.25)

\[
\mathcal{B}_X^{(1)} \rightarrow 0, \quad \mathcal{B}_Z^{(1)} \rightarrow 0, \quad \text{as} \ \tilde{Y} \rightarrow \infty.
\]
(4.26)

Thence,

\[
\mathcal{B}_X^{(1)} \equiv 0, \quad \mathcal{B}_Z^{(1)} \equiv 0,
\]
(4.27)

with

\[
\frac{\partial \mathcal{B}_Y^{(1)}}{\partial \tilde{Y}} = -\tilde{\beta}'(Z) e^{-\tilde{Y}},
\]
(4.28)

whence

\[
\mathcal{B}_Y^{(1)} = \tilde{\beta}'(Z) e^{-\tilde{Y}},
\]
(4.29)

where the prime denotes differentiation with respect to \( Z \). At \( \varepsilon^2 \), we have

\[
i \mathcal{B}_X^{(2)} = \frac{\partial \mathcal{B}_Y^{(2)}}{\partial \tilde{Y}},
\]
(4.30)

\[
\mathcal{B}_X^{(2)} = \frac{\partial^2 \mathcal{B}_X^{(2)}}{\partial \tilde{Y}^2} - (2\pi \Omega s i \tilde{\alpha}(Z) - \tilde{\alpha}''(Z)) e^{-\tilde{Y}},
\]
(4.31)

\[
\mathcal{B}_Y^{(2)} = \frac{\partial^2 \mathcal{B}_Y^{(2)}}{\partial \tilde{Y}^2} - (2\pi \Omega s \tilde{\alpha}(Z) + i \tilde{\alpha}''(Z)) e^{-\tilde{Y}},
\]
(4.32)
4.1.2 JX

used in the numerical solution that follows later.

\[
B = \text{whence} \quad B
\]

Using (3.5), we can now write

\[\begin{align*}
\mathcal{B}_X^{(2)} &= - \left( \pi \Omega_i \beta(Z) - \frac{1}{2} \beta''(Z) \right) \bar{y} e^{-\bar{y}}, \\
\mathcal{B}_Y^{(2)} &= - \left( \pi \Omega_i \beta(Z) + \frac{1}{2} \beta''(Z) \right) (\bar{Y} + 1) e^{-\bar{y}}, \\
\mathcal{B}_Z^{(2)} &= - \left( \pi \Omega_i \beta(Z) - \frac{1}{2} \beta''(Z) \right) \bar{y} e^{-\bar{y}}.
\end{align*}\]  

Furthermore, although the above analysis has been for the boundary layer near \( Y = 0 \) for \(|Z| < H/2\), it is straightforward to construct a composite solution for the entire steel region. This is done in the usual way by summing the inner and outer solutions and subtracting the common part [21]; in view of (4.13), this is effectively the same as replacing \( \bar{Y} \) by \( Y/\varepsilon \) in (4.20)–(4.22), (4.27), (4.29) and (4.36)–(4.38) above. Note also that Eqs. (4.7)–(4.10) were effectively not used at all in this analysis, although the equations that gave rise to them, (3.9), will be used in the numerical solution that follows later.

4.1.2 JX, JY, JZ, FX, FY, FZ

Using (3.5), we can now write

\[
J_X = \frac{1}{\varepsilon} \frac{\partial B_Z}{\partial Y} - \frac{\partial B_Y}{\partial Z}, \quad J_Y = \frac{\partial B_X}{\partial Z} - \frac{\partial B_Z}{\partial X}, \quad J_Z = \frac{\delta}{\varepsilon} \frac{\partial B_Y}{\partial X} - \frac{1}{\varepsilon} \frac{\partial B_X}{\partial Y}.
\]  

Since differentiating with respect to \( X \) will bring out a factor \( \Lambda \), and since \( \delta \Lambda = 1/\varepsilon \), this suggests the following expansions:

\[
\begin{align*}
J_k &= \varepsilon^{-1} J_k^{(0)} + J_k^{(1)} + \cdots, \\
F_k &= \varepsilon^{-1} F_k^{(0)} + F_k^{(1)} + \cdots,
\end{align*}\]

Hence, we find, \( \varphi = 2\pi \tau - \lambda X \),

\[\begin{align*}
J_X^{(0)} &= -\beta(Z) e^{-\bar{y}} \cos \varphi, \quad J_Y^{(0)} = -\beta(Z) e^{-\bar{y}} \sin \varphi, \quad J_Z^{(0)} = 0, \\
J_X^{(1)} &= -\alpha'(Z) e^{-\bar{y}} \sin \varphi, \quad J_Y^{(1)} = \alpha'(Z) e^{-\bar{y}} \cos \varphi, \quad J_Z^{(1)} = \beta'(Z) e^{-\bar{y}} \sin \varphi, \\
J_X^{(2)} &= \left( \pi \Omega_i \beta(Z)(1 - \bar{Y}) \sin \varphi - \frac{1}{2} \beta''(Z)(1 + \bar{Y}) \cos \varphi \right) e^{-\bar{y}}, \\
J_Y^{(2)} &= \left( \pi \Omega_i \beta(Z) \cos \varphi - \frac{1}{2} \beta''(Z) \sin \varphi \right) \bar{y} e^{-\bar{y}}, \\
J_Z^{(2)} &= -\left( \beta''(Z) \cos \varphi + 2\pi \Omega_i \alpha(Z) \sin \varphi \right) e^{-\bar{y}}, \\
F_X^{(0)} &= -\beta^2(Z) e^{-2\bar{y}} \sin \varphi \cos \varphi, \quad F_Y^{(0)} = \beta^2(Z) e^{-2\bar{y}} \cos^2 \varphi, \quad F_Z^{(0)} = 0, \\
F_X^{(1)} &= \left( \alpha'(Z) \beta(Z) \cos^2 \varphi - \alpha(Z) \beta'(Z) \sin^2 \varphi \right) e^{-2\bar{y}}.
\end{align*}\]
On longitudinal electromagnetic stirring in continuous casting

\[ F_Y^{(1)} = 0, \quad (4.48) \]
\[ F_Z^{(1)} = \left( \bar{\bar{b}} (Z) \bar{b}' (Z) \cos^2 \varphi + \bar{\bar{a}} (Z) \bar{a}' (Z) \right) e^{-2 \bar{Y}}, \quad (4.49) \]
\[ F_X^{(2)} = \left\{ - \pi \Omega_s \bar{b}^2 (Z) \bar{Y} \sin^2 \varphi + \left( \pi \Omega_s \bar{b}^2 (Z) \bar{Y} + \bar{\bar{a}} (Z) \bar{a}'' (Z) \right) \cos^2 \varphi \right. \]
\[ + \left( 2 \pi \Omega_s \bar{a}^2 (Z) - \bar{\bar{b}}'' (Z) \bar{\bar{b}} (Z) \bar{Y} - \bar{\bar{b}}^2 (Z) \right) \sin \varphi \cos \varphi \right\} e^{-2 \bar{Y}}, \quad (4.50) \]
\[ F_Y^{(2)} = \left\{ \frac{1}{2} \bar{\bar{b}} (Z) \bar{b}'' (Z) (1 + 2 \bar{Y}) - \bar{\bar{a}} (Z) \bar{a}'' (Z) \right\} \cos^2 \varphi \]
\[ - \pi \Omega_s \left( 2 \bar{a}^2 (Z) + \bar{\bar{b}}^2 (Z) (1 - 2 \bar{Y}) \right) \sin \varphi \cos \varphi \right\} e^{-2 \bar{Y}}, \quad (4.51) \]
\[ F_Z^{(2)} = \left\{ - \frac{1}{2} (\bar{\bar{a}} (Z) \bar{b}'' (Z) + 2 \bar{\bar{a}}' (Z) \bar{b}' (Z) + \bar{\bar{a}}'' (Z) \bar{b} (Z)) \sin \varphi \cos \varphi + \pi \Omega_s \bar{a} (Z) \bar{b} (Z) \right\} e^{-2 \bar{Y}}, \quad (4.52) \]
\[ \tilde{F}_X^{(0)} = 0, \quad \tilde{F}_Y^{(0)} = \frac{1}{2} \bar{b}^2 (Z) e^{-2 \bar{Y}}, \quad \tilde{F}_Z^{(0)} = 0, \quad (4.53) \]
\[ \tilde{F}_X^{(1)} = \frac{1}{2} (\bar{\bar{a}}' (Z) \bar{b} (Z) - \bar{\bar{a}} (Z) \bar{b}' (Z)) e^{-2 \bar{Y}}, \quad (4.54) \]
\[ \tilde{F}_Y^{(1)} = 0, \quad (4.55) \]
\[ \tilde{F}_Z^{(1)} = \left( \frac{1}{2} \bar{\bar{b}} (Z) \bar{b}' (Z) + \bar{\bar{a}} (Z) \bar{a}' (Z) \right) e^{-2 \bar{Y}}, \quad (4.56) \]
\[ \tilde{F}_X^{(2)} = \frac{1}{2} \bar{\bar{a}} (Z) \bar{a}'' (Z) e^{-2 \bar{Y}}, \quad (4.57) \]
\[ \tilde{F}_Y^{(2)} = \frac{1}{2} \left( \frac{1}{2} \bar{\bar{b}} (Z) \bar{b}'' (Z) (1 + 2 \bar{Y}) - \bar{\bar{a}} (Z) \bar{a}'' (Z) \right) e^{-2 \bar{Y}}, \quad (4.58) \]
\[ \tilde{F}_Z^{(2)} = \pi \Omega_s \bar{a} (Z) \bar{b} (Z) e^{-2 \bar{Y}}. \quad (4.59) \]

An unexpected difficulty now occurs if we have \( \bar{\bar{a}} = 1, \bar{\bar{b}} = 0 \), which we note is not a pathologically contrived counterexample, but in fact corresponds to the situation originally considered by Dubke et al. [3]; in this case, all three components of \( \mathbf{J}, \mathbf{F} \) and \( \tilde{\mathbf{F}} \) are zero at leading order, where

\[ \mathbf{F} = (F_X, F_Y, F_Z), \quad \tilde{\mathbf{F}} = (\tilde{F}_X, \tilde{F}_Y, \tilde{F}_Z); \]

moreover, the expansion given by Eq. (4.16) turns out not to be of the correct form. We therefore consider this case separately.

4.2 \( \bar{\bar{a}} \equiv 1, \bar{\bar{b}} \equiv 0 \)

It is evident from the outset that \( \mathcal{R}_Z \equiv 0 \), as is found by noting that the equations for \( \mathcal{R}_Z -(4.12) \) for \( k = Z \), subject to (4.4) and (4.13)—decouple from the others and have a trivial solution; thus, we only need consider (4.14) and (4.15) for \( k = X, Y \), which are now

\[ \frac{\partial \mathcal{R}_Y}{\partial \bar{Y}} = i \mathcal{R}_X, \quad (4.60) \]
\[ \left( 2 \pi \Omega_s \varepsilon^2 i + 1 \right) \mathcal{R}_k = \frac{\partial^2 \mathcal{R}_k}{\partial \bar{Y}^2} + \varepsilon^2 \frac{\partial^2 \mathcal{R}_k}{\partial Z^2}, \quad k = X, Y. \quad (4.61) \]
Setting, instead of (4.16),
\[
B_k = B_k^0 + \varepsilon^2 B_k^1 + O(\varepsilon^4), \quad k = X, Y, \\
\mathcal{B}_k = \mathcal{B}_k^0 + \varepsilon^2 \mathcal{B}_k^1 + O(\varepsilon^4),
\]
we have, at \( O(\varepsilon^0) \),
\[
\frac{\partial \mathcal{B}_k^0}{\partial \tilde{Y}} = i \mathcal{B}_X^0, \\
\mathcal{B}_k^0 = \frac{\partial^2 \mathcal{B}_k^0}{\partial \tilde{Y}^2}, \quad k = X, Y,
\]
subject to
\[
\mathcal{B}_X^0 = 1 \quad \text{at} \quad \tilde{Y} = 0, \\
\mathcal{B}_X^0, \mathcal{B}_Y^0 \to 0 \quad \text{at} \quad \tilde{Y} \to \infty,
\]
which leads to
\[
\mathcal{B}_X^0 = e^{-\tilde{Y}}, \quad \mathcal{B}_Y^0 = -ie^{-\tilde{Y}},
\]
and hence
\[
B_X^0 = e^{-\tilde{Y}} \cos \varphi, \quad B_Y^0 = e^{-\tilde{Y}} \sin \varphi.
\]

Next, at \( O(\varepsilon^2) \), we have
\[
\frac{\partial \mathcal{B}_k^1}{\partial \tilde{Y}} = i \mathcal{B}_X^1, \\
2\pi \Omega_s i \mathcal{B}_k^0 + \mathcal{B}_k^1 = \frac{\partial^2 \mathcal{B}_k^1}{\partial \tilde{Y}^2}, \quad k = X, Y,
\]
subject to
\[
\mathcal{B}_X^1 = 0 \quad \text{at} \quad \tilde{Y} = 0, \\
\mathcal{B}_X^1 \to 0 \quad \text{as} \quad \tilde{Y} \to \infty.
\]
It is then straightforward to obtain
\[
\mathcal{B}_X^1 = -\pi \Omega_s i \tilde{Y} e^{-\tilde{Y}}, \quad \mathcal{B}_Y^1 = -\pi \Omega_s \left( \tilde{Y} + 1 \right) e^{-\tilde{Y}},
\]
and thence
\[
B_X^1 = \pi \Omega_s \tilde{Y} e^{-\tilde{Y}} \sin \varphi, \quad B_Y^1 = -\pi \Omega_s \left( \tilde{Y} + 1 \right) e^{-\tilde{Y}} \cos \varphi.
\]

With the current choice of \( \tilde{\alpha} \) and \( \tilde{\beta} \), we will have \( J_X, J_Y \equiv 0 \), as is evident from (3.5) and the fact that \( B_X \) and \( B_Y \) do not depend on \( Z \), and it only remains to determine \( J_Z \); at leading order, this will be of \( O(\varepsilon) \), and we will need to set
\[
J_Z = \varepsilon J_Z^0 + O(\varepsilon^3).
\]
After a little algebra, we obtain
\[
J_Z^0 = -2\pi \Omega_s e^{-\tilde{Y}} \sin \varphi.
\]
Now, it is evident that \( F_X, F_Y \sim O(\varepsilon) \), \( F_Z \equiv 0 \), so that on setting
\[
F_k = \varepsilon F_k^{(0)} + O(\varepsilon^3) \,,
\]
\[
\tilde{F}_k = \varepsilon \tilde{F}_k^{(0)} + O(\varepsilon^3) \,, \quad k = X, Y,
\]
we have
\[
F_X^{(0)} = 2\pi \Omega_s e^{-2\tilde{Y}} \sin^2 \varphi, \quad F_Y^{(0)} = -2\pi \Omega_s e^{-2\tilde{Y}} \sin \varphi \cos \varphi,
\]
whence, we will find that
\[
\tilde{F}_X^{(0)} = \pi \Omega_s e^{-2\tilde{Y}}, \quad \tilde{F}_Y^{(0)} = 0;
\]
so, we would need to go to an even higher order in \( \varepsilon^2 \) to find the leading-order term for \( \tilde{F}_Y \). Thus, at \( \varepsilon^4 \), we have
\[
iB^{(2)}_X = \frac{\partial B^{(2)}_Y}{\partial \tilde{Y}},
\]
\[
2\pi^2 \Omega_s^2 \tilde{Y} e^{-\tilde{Y}} + B^{(2)}_X = \frac{\partial^2 B^{(2)}_X}{\partial \tilde{Y}^2},
\]
\[
- 2\pi^2 \Omega_s^2 \tilde{Y} e^{-\tilde{Y}} \text{e}^{(\tilde{Y} + 1)} e^{-\tilde{Y}} + B^{(2)}_Y = \frac{\partial^2 B^{(2)}_Y}{\partial \tilde{Y}^2},
\]
subject to
\[
B^{(2)}_X = 0 \text{ at } \tilde{Y} = 0, \quad B^{(2)}_X \to 0 \text{ as } \tilde{Y} \to \infty.
\]

Similarly, we obtain
\[
B^{(2)}_X = -\frac{\pi^2 \Omega_s^2}{2} \left( \tilde{Y}^2 + 2 \tilde{Y} \right) e^{-\tilde{Y}}, \quad B^{(2)}_Y = \frac{\pi^2 \Omega_s^2}{2} \left( \tilde{Y}^2 + 3 \tilde{Y} + 3 \right) e^{-\tilde{Y}},
\]
and thence
\[
B^{(2)}_X = -\frac{\pi^2 \Omega_s^2}{2} \left( \tilde{Y}^2 + 2 \tilde{Y} \right) e^{-\tilde{Y}} \cos \varphi, \quad B^{(2)}_Y = -\frac{\pi^2 \Omega_s^2}{2} \left( \tilde{Y}^2 + 3 \tilde{Y} + 3 \right) e^{-\tilde{Y}} \sin \varphi,
\]
which gives
\[
J_{Z}^{(1)} = 2\pi^2 \Omega_s^2 \left( \tilde{Y} + 1 \right) e^{-\tilde{Y}} \cos \varphi.
\]

Finally, we have
\[
F_X^{(1)} = -4\pi^2 \Omega_s^2 \left( \tilde{Y} + 1 \right) e^{-2\tilde{Y}} \sin \varphi \cos \varphi, \quad F_Y^{(1)} = -2\pi^2 \Omega_s^2 \left( \tilde{Y} \sin^2 \varphi - \left( \tilde{Y} + 1 \right) \cos^2 \varphi \right) e^{-2\tilde{Y}},
\]
thus,
\[
\tilde{F}_X^{(1)} = 0, \quad \tilde{F}_Y^{(1)} = \pi^2 \Omega_s^2 e^{-2\tilde{Y}}.
\]

In dimensional terms, we recover the principal quantities of interest as
\[
B_x = B_0 e^{-\lambda y} \cos \left(\omega t - \lambda x\right), \quad (4.91)
\]
\[
B_y = B_0 e^{-\lambda y} \sin \left(\omega t - \lambda x\right), \quad (4.92)
\]
\[ J_z = -\frac{\sigma_s \omega B_0}{\lambda} e^{-\lambda y} \cos (\omega t - \lambda x), \]  
\[ F_x = \frac{\sigma_s \omega B_0^2}{\lambda} e^{-2\lambda y} \cos^2 (\omega t - \lambda x), \]  
\[ F_y = -\frac{\sigma_s \omega B_0^2}{\lambda} \left\{ \sin (\omega t - \lambda x) \cos (\omega t - \lambda x) + \frac{\sigma_s \eta_s \omega}{2 \lambda^2} \left[ \lambda y - (2\lambda y + 1) \cos^2 (\omega t - \lambda x) \right] \right\} e^{-2\lambda y}, \]  

and thence
\[ \tilde{F}_x = \frac{\sigma_s \omega B_0^2}{2\lambda} e^{-2\lambda y}, \quad \tilde{F}_y = \frac{\sigma_s^2 \eta_s \omega^2 B_0^2}{4\lambda^3} e^{-2\lambda y}. \]  

Note that, in (4.95), we have written the expansion to two terms, in order to include the first term that provides a non-zero contribution to (4.96); in (4.91)–(4.94), we have written just the first term.

4.3 Reconstruction of the earlier solution [3]

It is evident that we can use the results in Sect. 4.1 to obtain a solution for which \( B_y \) behaves at \( y = 0 \) in the same way as the solution of Dubke et al. [3]. If we replace (2.10) by
\[ B_x = -B_0 \sin (\omega t - \lambda x), \]  
we should now set
\[ B_k = \text{Re} \left( i \mathcal{B}_k (Y, Z) e^{i(2\pi t - \Lambda X)} \right), \quad k = X, Y, \]  
where \( \mathcal{B}_k \) will now satisfy the same equations as in Sect. 4.2. Omitting all of the intervening algebraic details, we will obtain, instead of (4.91)–(4.95),
\[ B_x = B_0 \left\{ \frac{\sigma_s \eta_s \omega}{2 \lambda} y \cos (\omega t - \lambda x) \right\} e^{-\lambda y}, \]  
\[ B_y = B_0 e^{-\lambda y} \cos (\omega t - \lambda x), \]  
\[ J_z = -\frac{\sigma_s \omega B_0}{\lambda} e^{-\lambda y} \cos (\omega t - \lambda x), \]  
\[ F_x = \frac{\sigma_s \omega B_0^2}{\lambda} e^{-2\lambda y} \cos^2 (\omega t - \lambda x), \]  
\[ F_y = \frac{\sigma_s \omega B_0^2}{\lambda} \left\{ \sin (\omega t - \lambda x) \cos (\omega t - \lambda x) + \frac{\sigma_s \omega}{2 \lambda^2} \left[ \lambda y + 1 - (2\lambda y + 1) \cos^2 (\omega t - \lambda x) \right] \right\} e^{-2\lambda y}, \]  

and thence
\[ \tilde{F}_x = \frac{\sigma_s \omega B_0^2}{2\lambda} e^{-2\lambda y}, \quad \tilde{F}_y = \frac{\sigma_s^2 \eta_s \omega^2 B_0^2}{4\lambda^3} e^{-2\lambda y}. \]  

Consequently, although the forms in (4.98)–(4.102) are different to those in (4.91)–(4.95), the expressions for \( \tilde{F}_x \) and \( \tilde{F}_y \) are identical.

5 Numerical solution

In order to ascertain the correctness of the asymptotic analysis, Eqs. (2.6) and (2.7), subject to (2.10)–(2.14), were also solved numerically. For this, the Magnetic Fields module of the Comsol Multiphysics software mentioned previously was used. Second-order Lagrangian quadrilateral elements were employed on a mesh having approximately 70,000 elements, corresponding to around 1.4 million degrees of freedom. The computational mesh...
that was used was decided upon after a grid independence study, although, in the interest of brevity, the results of this are not presented here; the fact that we have obtained good agreement with the asymptotic results, as will be seen in Sect. 6, means that we can be sure that we have computed accurately enough. As regards the size of the computational domain, its outer edge was taken to be a half-cylinder of radius 0.4 m and height 1.2 m. The geometry and the mesh are shown in Fig. 3.

For the numerical integration, adaptive time-stepping was used and the convergence criterion at each time step was taken as

$$\left( \frac{1}{N_{\text{dof}}} \sum_{i=1}^{N_{\text{dof}}} \left( \frac{|E_i|}{A_i + R|U_i|} \right)^2 \right)^{\frac{1}{2}} < 1,$$

where \((U_i)\) is the solution vector corresponding to the solution at each time step, \(E_i\) is the estimated error in the latest approximation to the \(i\)th component of the true solution vector, \(A_i\) is the absolute tolerance for the \(i\)th degree of freedom, and \(R\) is the relative tolerance; for the computations, \(R = 10^{-3}\), \(A_i = 10^{-4}\) for \(i = 1, \ldots, N_{\text{dof}}\) were used, where \(N_{\text{dof}}\) is the number of degrees of freedom. Note that all computations were carried out on an architecture with an Intel® Core™ i9-7940X CPU @ 3.10 GHz×14 processor with 32 GB RAM. The typical computation time was of the order of 2–3 h; this constitutes running the model for three periods of oscillation, corresponding to 0.06 s, in order to minimize the effect of the initial transient, so as to obtain appropriate data for computing the components of the time-averaged Lorentz force.

6 Results

In this section, we consider first results for the case when \(\alpha = B_0, \beta = 0\), and then for a more general case when both \(\alpha\) and \(\beta\) are functions of \(z\).
6.1 $\alpha(z) = B_0, \beta(z) = 0$

Figure 4a and b compare $B_x$ and $B_y$, respectively, as functions of $y$ at $z = 0$ m, $t = 0.06$ s, $x = -0.6$ m, using the solution from [3], our asymptotic solution and the full numerical solution. Note that we have plotted the asymptotic solution to two terms, so as to demonstrate how well it agrees with the full numerical solution; since $\omega t - \lambda x$ is an even multiple of $\pi$ (16 in fact) for these values of $x$ and $t$, we would have had just the zero solution to one term for $B_x$. Moreover, Fig. 4a in particular illustrates that the asymptotic solution is better able to reproduce the numerical solution than the analytical solution from [3].

Also of interest is to see whether the full numerical solution displays the boundary layer indicated by the analysis and to see the behavior near $|z| = h/2$. This is shown in Fig. 5 which shows the contours of $B_y$ for spacings of 0.002 T for $0.002 \leq B_y \leq 0.02$ T, as given by the numerical solution for $t = 0.06$ s, $x = -0.6$ m; the boundary layer is evident, as is its breakdown near $|z| = h/2$.

Figure 6a and b compare $F_x$ and $F_y$, respectively, as functions of $y$ at $z = 0$ m, $t = 0.06$ s, $x = -0.6$ m, as obtained by the three approaches. This time, the discrepancy between the numerical solution and the solution from [3] is evident in Fig. 6b, whereas the two-term asymptotic solution once again agrees well in both cases with the full numerical solution.

Figure 7a and b compare $\bar{F}_x$ and $\bar{F}_y$, respectively, as functions of $y$ at $z = 0$ m, $x = -0.6$ m, as obtained by the three approaches. The results of all three methods agree with each other, and the overall situation is reminiscent of the corresponding situation in rotary EMS, where an earlier model [2,7] provides the correct solution for the time-averaged Lorentz force components, even though the time-dependent solution is incorrect [8]. Note that although the profile for $\bar{F}_y$ is but the leading term in the asymptotic expansion, it is actually constituted from the third terms in the expansions for $B_x$ and $B_y$.

6.2 $\alpha(z) = B_0 (z/b)^2, \beta(z) = B_0 (z/b)^2$

Since it reasonable to expect symmetry about $z = 0$ m, we take for $\alpha$ and $\beta$ the simplest possible profiles for which neither is constant, i.e. quadratic powers in $z$. In particular, we take

$$\alpha = \beta = B_0 (z/b)^2; \quad (6.1)$$

thus

$$[\alpha] = [\beta] = B_0, \quad (6.2)$$

Springer
The resulting expressions for the components of $\mathbf{B}$, $\mathbf{J}$, $\mathbf{F}$ and $\bar{\mathbf{F}}$ are given in Appendix B.

We omit showing comparisons between the asymptotic and numerical solutions for the components of $\mathbf{B}$, in the manner of Fig. 4, as the conclusions are qualitatively similar. Instead, we show first in Fig. 8 $F_x$ at $y = 0$ m,
Fig. 7 Comparison of (a) \( \bar{F}_x \) and (b) \( \bar{F}_y \) vs. \( y \) for \( z = 0 \) m, \( x = -0.6 \) m, using the solution from [3], the asymptotic solution in (4.103), and the full numerical solution.

Fig. 8 Comparison of the asymptotic and numerical solutions for \( F_x \) vs. \( t \) at \( y = 0, z = 0.0875 \) m, \( x = -0.6 \) m, \( 0.04 \) s \( \leq t \leq 0.06 \) s. The 1-, 2- and 3-term asymptotic solutions are constituted using (4.46), (4.47) and (4.50), with the 3-term solution being the same as that in Eq. (B.7).

\( z = 0.0875 \) m, \( x = -0.6 \) m as a function of time on the third period of oscillation in \( B_x \), as this illustrates several key points:

- the 2- and 3-term solutions agree much better with the numerical solution than does the 1-term solution;
- the second term is necessary because of the \( O(\varepsilon) \) dependence of the expansion;
Fig. 9  Comparison of (a) $\bar{F}_x$, (b) $\bar{F}_y$ and (c) $\bar{F}_z$ vs. $y$
for $z = 0.0875$ m, $x = -0.6$ m, using the
asymptotic solution and the
full numerical solution

- the numerical solution has already achieved periodic behavior, since it agrees well with the analytical solution into which periodicity is already inbuilt;
- the frequency of $F_x$ is twice that of $B_x$.

We comment also that we have not shown the solution at $z = 0$, as was done in the case where $\alpha = B_0$, $\beta = 0$, as it will be identically zero for these profiles of $\alpha$ and $\beta$. Moreover, the small discrepancy between the three-
term asymptotic solution and numerical solution in Fig. 8 is most likely due to the fact that, although the numerical solution is mesh-independent with respect to $B_X$, $B_Y$ and $B_Z$, a still finer mesh would be required to achieve mesh-independence for their derivatives; of course, the components of the Lorentz force contain the derivatives. However, as we were already at the operating limit as regards RAM on the computer that was used, we did not attempt a solution on an even finer mesh.

Finally, in Fig. 9, we show $\bar{F}_x$, $\bar{F}_y$, $\bar{F}_z$ vs. $y$ at $z = 0.0875$ m, $x = -0.6$ m. Clearly, these have been computed correctly. Note here that a 3-term expansion is required to obtain a non-zero leading term for all three force components, because of the choice of $\alpha$ and $\beta$; in particular, $\bar{F}_X^{(1)} = 0$ from (4.54) so that the first non-zero contribution to $F_X$ is at $O(\epsilon^2)$.

7 Conclusion

This paper has revisited an early, yet still often-cited, mathematical model for longitudinal electromagnetic stirring in the continuous casting of rectangular steel blooms [3–6]. As indicated in Appendix A, there are mathematical inconsistencies in the way the model equations were originally posed, leading to the possibility of non-unique solutions; our analysis has resolved this issue. However, it appears that the original model worked well enough because of the parameter regime in which it was used. Furthermore, our analysis identified the key dimensionless parameter, $\Delta$, to be the product of the bloom width, the reciprocal of the inductor pole pitch and $\pi$. In typical applications, this parameter is large, which leads, physically, to a boundary layer near the stirrer surface and, mathematically, a singular perturbation analysis in terms of the small parameter $\epsilon = 1/\Delta$. Moreover, it was found that the expressions found originally in [3–6] were not of the most general form that can occur: in those, the magnitudes of the Lorentz force components depend on the oscillation frequency, whereas in general they do not. In addition, in the most general case, the magnetic flux density components expand in powers of $\epsilon$, whereas they expand in powers of $\epsilon^2$ in the original case. The subsequent results of this analysis were compared with those of transient 3D computations of the Maxwell equations using finite element methods and good agreement was found.

The current methodology may now be extended to derive corresponding expressions for the components of the Lorentz force in the continuous casting of slabs, wherein stirring is horizontal, i.e. perpendicular to the casting direction [22]; with reference to Fig. 1, this will mean that a wave of the form $\cos(\omega t - \lambda z)$, rather than $\cos(\omega t - \lambda x)$, is applied. Moreover, and again with reference to Fig. 1, it is the case than $b/h \ll 1$, which means the possibility of simplification via a second asymptotically small parameter.

Finally, we point out that determining how the magnetic flux density is perturbed, i.e. at $O(\epsilon)$ or $O(\epsilon^2)$, may be of significance because it will also be perturbed by the melt velocity field. As this perturbation is characterized by the magnetic Reynolds number, $R_m$, which is itself typically small, the size of $R_m$ in relation to $\epsilon$ and $\epsilon^2$ will determine whether the next-order perturbation is due to the velocity field ($R_m \gg \epsilon$ or $R_m \gg \epsilon^2$, depending on the boundary conditions) or the inductor ($R_m \ll \epsilon$ or $R_m \ll \epsilon^2$).

Appendix A: Solution from Dubke et al. [3]

Before summarizing the solution from [3], we re-cap how it was obtained. All quantities were assumed to be independent of \( z \), and \( B_z \) was taken to be zero. The governing equations [A-3] and [A-8] in [3] were then taken to be, for \( y \geq 0 \) and \(-\infty < x < \infty\),

\[
\frac{\partial B_x}{\partial x} + \frac{\partial B_y}{\partial y} = 0, \tag{A.1}
\]

\[
\sigma \eta \frac{\partial B_y}{\partial t} = \frac{\partial^2 B_y}{\partial x^2} + \frac{\partial^2 B_y}{\partial y^2}, \tag{A.2}
\]

respectively; for simplicity, since it does not affect the gist of the argument, we have omitted in (A.2) an advection term that was present in [A-8]. A primary objection already at this stage is that there should also be an equation for \( B_x \) which has the same form as (A.2). Thence, assuming that \( B_y = A(y) e^{i(\omega t - \lambda x)} \), prescribing \( B_y \) at \( y = 0 \) and assuming that \( B_y \to 0 \) as \( y \to \infty \), leads to a unique solution for \( A(y) \) from (A.2); the resulting expression for \( B_x \) is then substituted into (A.1), which is then integrated with respect to \( x \) to obtain an expression for \( B_x \). However, the correctness of this step is also debatable, since it should introduce a new function of \( y \) and \( t \), which was not accounted for in [3]. Furthermore, even if such a function had been correctly introduced, it is not clear how it would be determined, since there are no boundary conditions on \( B_x \) that could help determine it.

Now, with \( \phi = \omega t - \lambda x - (\text{Im}\gamma) y \), the key expressions are

\[
B_x = -\frac{B_0}{\lambda} e^{-(\text{Re}\gamma) y} \{ (\text{Re}\gamma) \sin \phi + (\text{Im}\gamma) \cos \phi \}, \tag{A.3}
\]

\[
B_y = B_0 e^{-(\text{Re}\gamma) y} \cos \phi, \tag{A.4}
\]

\[
J_z = -\frac{\sigma_s \omega B_0}{\lambda} e^{-(\text{Re}\gamma) y} \cos \phi, \tag{A.5}
\]

\[
F_x = \frac{\sigma_s \omega B_0^2}{\lambda^2} e^{-2(\text{Re}\gamma) y} \cos^2 \phi, \tag{A.6}
\]

\[
F_y = \frac{\sigma_s \omega B_0^2}{\lambda^2} e^{-2(\text{Re}\gamma) y} \cos \phi \{ (\text{Re}\gamma) \sin \phi + (\text{Im}\gamma) \cos \phi \}, \tag{A.7}
\]

where \( \text{Im} \) denotes the imaginary part of a complex number and

\[
\gamma = \sqrt{\sigma_s \eta_s \omega + \lambda^2}, \tag{A.8}
\]

so that

\[
\text{Re}\gamma = \sqrt{\frac{\lambda^2}{2} + \frac{1}{2} \sqrt{\lambda^4 + 4 \sigma_s^2 \eta_s^2 \omega^2}}, \quad \text{Im}\gamma = \sqrt{-\frac{\lambda^2}{2} + \frac{1}{2} \sqrt{\lambda^4 + \sigma_s^2 \eta_s^2 \omega^2}}, \tag{A.9}
\]

with

\[
\bar{F}_x = \frac{\sigma_s \omega B_0^2 e^{-2(\text{Re}\gamma) y}}{2\lambda}, \quad \bar{F}_y = \frac{\sigma_s \omega B_0^2 (\text{Im}\gamma) e^{-2(\text{Re}\gamma) y}}{2\lambda^2}. \tag{A.10}
\]

We may note at this point that the expressions in (A.10) are not identical to those in (4.103), even though the agreement in Fig. 7 was very good. This is explained by noting that, on using the data in Table 1, \( \lambda^2/\sigma_s \eta_s \omega \approx 9.7 \), which justifies considering \( \lambda^2 \gg \sigma_s \eta_s \omega \); thus, the expressions in (A.9) can be approximated as

\[
\text{Re}\gamma \approx \lambda, \quad \text{Im}\gamma \approx \frac{\sigma_s \eta_s \omega}{2\lambda}, \tag{A.9}
\]

rendering (4.103) and (A.10) identical.
Appendix B: Solution with $\alpha (z) = B_0 (z/b)^2$, $\beta (z) = B_0 (z/b)^2$

With $\phi = \omega t - \lambda x$ this time, the analysis in Eqs. (4.20)–(4.59) results in

\[
B_x = \frac{B_0}{b^2} \left[ \frac{\eta_s \omega \sigma_s}{2\lambda} \left( 1 - \lambda \right) \sin \phi + \left( \frac{1}{\lambda} + \left( \frac{1}{\lambda} + \lambda \right) \right) \cos \phi \right] e^{-\lambda y}, \tag{B.1}
\]

\[
B_y = \frac{B_0}{b^2} \left[ \frac{\eta_s \omega \sigma_s}{2\lambda} \left( \lambda^2 (\lambda y + 1) + \lambda \right) \cos \phi + \left( \frac{2}{\lambda} \right) \cos \phi \right] e^{-\lambda y}, \tag{B.2}
\]

\[
B_z = \frac{B_0}{b^2} \left[ \frac{\eta_s \omega \sigma_s}{2\lambda} \left( y - \lambda \right) \right] \cos \phi + \left( \frac{1}{\lambda} + \lambda \right) \cos \phi \right] e^{-\lambda y}, \tag{B.3}
\]

\[
J_x = \frac{B_0}{b^2} \left[ \left( -2z + \frac{\eta_s \omega \sigma_s}{\lambda} (1 - \lambda y) \right) \cos \phi - \left( \frac{1}{\lambda} + \lambda \right) \cos \phi \right] e^{-\lambda y}, \tag{B.4}
\]

\[
J_y = \frac{B_0}{b^2} \left[ \left( y + \lambda \right) \cos \phi + \left( \frac{2z + \eta_s \omega \sigma_s}{\lambda} \right) \cos \phi \right] e^{-\lambda y}, \tag{B.5}
\]

\[
J_z = \frac{B_0}{b^2} \left[ \left( 2z - \frac{\eta_s \omega \sigma_s}{\lambda} \right) \cos \phi - \frac{2}{\lambda} \cos \phi \right] e^{-\lambda y}, \tag{B.6}
\]

\[
F_x = \frac{B_0^2}{\eta_s b^4} \left[ - \left( 2 + \frac{\eta_s \omega \sigma_s}{2\lambda} \right) \cos \phi + \left( \frac{2}{\lambda} + \left( 2 + \frac{\eta_s \omega \sigma_s}{2\lambda} \right) \right) \cos \phi \right] e^{-\lambda y}, \tag{B.7}
\]

\[
F_y = \frac{B_0^2}{\eta_s b^4} \left[ \left( \frac{1}{\lambda} \right) (3 + 2\lambda y + \lambda^2) \cos \phi - \frac{\eta_s \omega \sigma_s}{2\lambda} (3 - 2\lambda y) \cos \phi \right] e^{-\lambda y}, \tag{B.8}
\]

\[
F_z = \frac{B_0^2}{\eta_s b^4} \left[ -2z^3 \cos \phi - \frac{6}{\lambda} \cos \phi - \left( 2z^3 + \frac{\eta_s \omega \sigma_s}{2\lambda} e^4 \right) \cos \phi \right] e^{-\lambda y}, \tag{B.9}
\]

\[
\tilde{F}_x = \frac{B_0^2}{\eta_s \lambda b^4} e^{-2\lambda y}, \tag{B.10}
\]

\[
\tilde{F}_y = \frac{B_0^2}{2\eta_s \lambda b^4} \left[ (3 + 2\lambda y) z^2 + \lambda^2 z^4 \right] e^{-2\lambda y}, \tag{B.11}
\]

\[
\tilde{F}_z = \frac{B_0^2}{\eta_s \lambda b^4} \left( -3 \lambda z^2 + \eta_s \omega \sigma_s \right) e^{-2\lambda y}. \tag{B.12}
\]
