Abstract

Recently, several Turán type problems were solved by the powerful random algebraic method. In this paper, we use this tool to construct various multi-hypergraphs to obtain some tight lower bounds and determine the dependence on some specified large constant for different Turán problems. We investigate three important objects including complete \(r\)-partite \(r\)-uniform hypergraphs, complete bipartite hypergraphs and Berge theta hypergraphs. More specifically, for complete \(r\)-partite \(r\)-uniform hypergraphs, we show that if \(s_r\) is sufficiently larger than \(s_1, s_2, \ldots, s_{r-1}\), then

\[ \text{ex}_r(n, K_{s_1, s_2, \ldots, s_r}^{(r)}) = \Theta(s_r^{\frac{1}{s_1 s_2 \cdots s_{r-1} n^{r-1}}} n^{r-1}). \]

For complete bipartite hypergraphs, we prove that if \(s\) is sufficiently larger than \(t\), we have

\[ \text{ex}_r(n, K_{s,t}^{(r)}) = \Theta(s^{\frac{1}{r} n^{r-1}}). \]

In particular, our results imply that the famous Kövari-Sós-Turán’s upper bound \(\text{ex}(n, K_{s,t}) = O(t^\frac{1}{s} n^{2-\frac{1}{s}})\) is tight when \(t\) is large.

1 Introduction

The study of Turán problems is one of the essential ingredients in extremal graph theory. In 1907, Mantel [26] first showed that every $n$-vertex graph with more than $\binom{n}{2}$ edges contains a triangle. Later Turán [30] generalized this result to $K_{t}$-free graphs for $t \geq 4$. For general graph $H$, Erdős and Stone [13] gave the asymptotic results for the Turán number $\text{ex}(n, H)$. However, to determine the exact asymptotic results for $\text{ex}(n, H)$ is challenging when $H$ is a bipartite graph. Complete bipartite graphs and even cycles are two important objects when we study such degenerate Turán problems. For complete bipartite graphs, the result of Kövari, Sós and Turán [23] showed that $\text{ex}(n, K_{s,t}) = O(n^{2-\frac{1}{s}})$ for any integers $t > s$. When $s = 2, 3$, Erdős, Rényi and Sós [12] and Brown [5] gave the matched lower bounds respectively. For general $R´ onyai and Szab´ o [1]. Recently, Blagojevi´ c, Bukh, Karasev [2] gave a new type of $K_{s,t}$-free graph via topological obstructions and algebraic constructions. Then Bukh [6] established an elegant method, which is named random algebraic construction, to show that $\text{ex}(n, C_{4})$ is sufficiently larger than $\sqrt{n}$. From then on, the random algebraic method was applied to several Turán type problems, see [7, 9, 10, 25, 34].

For even cycles, the extremal results of $\text{ex}(n, C_{2\ell})$ were first studied by Erdős [11], and then Bondy and Simonovits [4] gave a general upper bound $\text{ex}(n, C_{2\ell}) \leq 100\ell n^{1+\frac{1}{2\ell}}$. Recently, Bukh and Jiang [8] improved the upper bound to $\text{ex}(n, C_{2\ell}) \leq 80\sqrt{\ell}\log \ell n^{1+\frac{1}{2\ell}}$, and this upper bound is the current record. However, the order of magnitude for $\text{ex}(n, C_{2\ell})$ is unknown for any $\ell \notin \{2, 3, 5\}$, see [5, 12, 33]. For general $\ell$, the best known lower bounds for $\text{ex}(n, C_{2\ell})$ (except for $\text{ex}(n, C_{14})$, see [29]) were obtained by Lazebnik, Ustimenko and Woldar [24].

Due to the similarity of theta graphs and even cycles, the recent research on theta graphs has been widely concerned. Let theta graph $\Theta_{\ell,t}$ be a graph made of $t$ internally disjoint paths of length $\ell$ connecting two endpoints. Since it is unclear whether $\text{ex}(n, C_{2\ell}) = \Omega(n^{1+\frac{1}{2\ell}})$ holds in general, the study of $\text{ex}(n, \Theta_{\ell,t})$ is of interest. Faudree and Simonovits [14] first showed the general upper bound $\text{ex}(n, \Theta_{\ell,t}) = O_{\ell,t}(n^{1+\frac{1}{2\ell}})$. Recently, Conlon [10] showed the matched lower bounds when $t$ is a sufficiently large constant. After that Bukh and Tait [9] studied the behavior of $\text{ex}(n, \Theta_{\ell,t})$ when $\ell$ is fixed and $t$ is very large, and they further determined the dependence on $t$ when $\ell$ is odd. When $\ell$ and $t$ are relatively small, Verstraëte and Williford [32] showed that $\text{ex}(n, \Theta_{4,3}) \geq (\frac{1}{2} - o(1))n^{\frac{5}{2}}$, and this result is perhaps the evidence that the Turán number of the octagon is also of order $n^{\frac{5}{2}}$.

On the contrary to the simple graph cases, there are only a few results on hypergraph Turán problems. There are two ways of generalizing complete bipartite graphs to hypergraphs. The first one is complete $r$-partite $r$-uniform hypergraph $K^{(r)}_{r, r, \ldots, r}$, Mubayi [27] conjectured that $\text{ex}_{r}(n, K^{(r)}_{r, r, \ldots, r}) = \Theta(n^{\frac{r}{r-1, r-2, \ldots, r-1}})$, where $s_{1} \leq s_{2} \leq \cdots \leq s_{r}$, and he proved this conjecture in
certain situations. Recently, Ma, Yuan and Zhang [25] showed that if \( s_r \) is sufficiently larger than \( s_1, s_2, \ldots, s_{r-1} \), then this conjecture is true. The other object is complete bipartite hypergraph \( K^{(r)}_{s,t} \). In [28], Mubayi and Verstraët showed some general bounds for \( \text{ex}_r(n, K^{(r)}_{s,t}) \) when \( s < t \).

More recently, Xu, Zhang and Ge [34] gave the lower bound \( \text{ex}_r(n, K^{(r)}_{s,t}) = \Omega(n^{r - \frac{1}{2}}) \) when \( s \) is sufficiently larger than \( t \), and the general upper bound \( \text{ex}_r(n, K^{(r)}_{s,t}) = O(s^t n^{r - \frac{1}{2}}) \) when \( s \) is large.

The Turán problem for cycles in hypergraphs has been investigated for so-called Berge cycles. Győri [18] first determined \( \text{ex}_r(n, C^{B}_3) \) for all \( n \), then Bollobás and Győri [3] showed that \( \text{ex}_3(n, C^{B}_3) = O(n^{\frac{3}{2}}) \). Győri and Lemons [19] showed the general upper bounds \( \text{ex}_r(n, C^{B}_2) = O(n^{1+\frac{1}{r}}) \) and \( \text{ex}_r(n, C^{B}_{2\ell + 1}) = O(n^{1+\frac{1}{r\ell}}) \) for all \( \ell \geq 2 \) and \( r \geq 3 \). It is known in [16] that \( \text{ex}_r(n, C^{B}_4) = \Theta(n^{\frac{3}{2}}) \) when \( 2 \leq r \leq 6 \), but the order of magnitude is still unknown for \( r \geq 7 \). It is widely open whether the general upper bounds are tight for all \( r, \ell \geq 3 \). For more extremal results of Berge cycles, we refer the readers to [17, 21, 31] and the references therein.

Since there are few exact asymptotic results of \( \text{ex}_r(n, C^{B}_{2\ell}) \), we are interested in the generalization of theta graphs to hypergraphs. Let \( r \)-uniform Berge theta hypergraph \( \Theta^{B}_{\ell,t} \) be a set of distinct vertices \( x, y, v_1, \ldots, v_{\ell-1}, \ldots, v_{t-1}, \ldots, v_{\ell-1} \) and a set of distinct edges \( e_1, \ldots, e_{\ell}, \ldots, e_1, \ldots, e_1 \) such that \( \{x, v_i\} \subset e_i \), \( \{v_{i-1}, v_i\} \subset e_j \) and \( \{v_{i-1}, y\} \subset e_k \) for \( 1 \leq i \leq t \) and \( 2 \leq j \leq \ell - 1 \). Recently, He and Tait [20] studied the Turán number \( \text{ex}_r(n, \Theta^{B}_{\ell,t}) \), in particular, they showed that for fixed \( \ell \) and \( r \), there is a large constant \( t \) such that \( \text{ex}_r(n, \Theta^{B}_{\ell,t}) \) can be determined in order of magnitude.

As far as we know, the random algebraic method always requires one of some parameters to be very large, therefore determining the dependence on this large parameter is interesting.

In this work, we investigate three important objects including complete \( r \)-partite \( r \)-uniform hypergraphs, complete bipartite hypergraphs and Berge theta hypergraphs. Our main idea is to construct the random multi-hypergraphs via random algebraic method, and our main contributions in this paper are listed as follows.

- **Complete \( r \)-partite \( r \)-uniform hypergraphs:**

  **Theorem 1.1.** For any positive integers \( s_1, s_2, \ldots, s_{r-1} \) and \( r \geq 2 \), when \( s_r \) is sufficiently large, we have

  \[
  \text{ex}_r(n, K^{(r)}_{s_1, s_2, \ldots, s_r}) = \Omega(s_r^{\frac{1}{s_1+1}} n^{r-\frac{1}{s_1}} n^{s_{r-1} \frac{1}{s_{r-1}+1}})
  \]

  By the result of [25, Lemma 3.1], the dependence on large \( s_r \) is tight.

- **Complete bipartite hypergraphs:**

  **Theorem 2.** For any positive integers \( t \) and \( r \geq 2 \), when \( s \) is sufficiently large, we have

  \[
  \text{ex}_r(n, K^{(r)}_{s,t}) = \Omega(s^t n^{r-\frac{1}{2}}).
  \]
By the result of [34, Theorem 1.3], the dependence on large $s$ is tight.

As a corollary, both of Theorems 1.1 and 1.2 imply that the upper bound of Kővari, Sós and Turán [23] is tight when $t$ is large.

**Corollary 1.3.** For given positive integer $s$, there exists a large $t$ such that

$$
\text{ex}(n, K_{s,t}) = \Theta(t^{\frac{1}{s}n^{2-\frac{1}{s}}}).
$$

- Berge theta hypergraphs:

For general $\ell$, by the upper bound for $\text{ex}(n, \Theta_{\ell,t}) = O(t^{1-\frac{4}{7}n^{1+\frac{1}{7}}})$ in [9], Dánél, Abhishek and Cory [15] showed the following upper bound when $t$ is sufficiently large.

**Theorem 1.4** ([15]). For fixed $\ell \geq 2$, when $t$ is sufficiently large, we have

$$
\text{ex}_{r}(n, \Theta_{\ell,t}^{\ell}) = O_{\ell,r}(t^{r-1-\frac{1}{7}n^{1+\frac{1}{7}}}).
$$

However we do not know whether the general upper bound is tight. Using our tools, we can show a lower bound as follows.

**Theorem 1.5.** Let $\ell \geq 2$ be a fixed integer, when $t$ is sufficiently large, we have

$$
\text{ex}_{r}(n, \Theta_{\ell,t}^{\ell}) = \Omega_{\ell,r}(t^{\frac{1}{\ell}n^{1+\frac{1}{\ell}}}).
$$

The rest of this paper is organized as follows. In Section 2 we introduce some basic facts about random algebraic method. In Section 3 we develop the random algebraic method to construct various multi-hypergraphs and then prove our main results of complete $r$-partite $r$-uniform hypergraphs, complete bipartite hypergraphs and Berge theta hypergraphs. Finally we conclude in Section 4 and provide some remarks and open problems on the main topics.

## 2 Preliminaries of random algebraic method

Let $t, r$ be positive integers with $r \geq 2$, $q$ be a sufficiently large prime power, and $\mathbb{F}_q$ be the finite field of order $q$. Let $X^i = (X^i_1, X^i_2, \ldots, X^i_t) \in \mathbb{F}_q^t$ for each $i \in [r]$. Consider polynomials $f \in \mathbb{F}_q[X^1, X^2, \ldots, X^r]$ with $rt$ variables over $\mathbb{F}_q$. We say such a polynomial $f$ has degree at most $d$ in $X^i$, if each of its monomials has degree at most $d$ with respect to $X^i$, that is, $(X^i_1)^{\alpha_1}(X^i_2)^{\alpha_2} \cdots (X^i_t)^{\alpha_t}$ satisfies $\sum_{j=1}^{t} \alpha_j \leq d$. Moreover, a polynomial $f$ is called symmetric if exchanging $X^i$ with $X^j$ for every $1 \leq i \leq j \leq r$ does not affect the value of $f$. Let
\[ \mathcal{P}_d \subseteq \mathbb{F}_q[X^1, X^2, \ldots, X^r] \] be the set of all symmetric polynomials of degree at most \( d \) in \( X^i \) for every \( 1 \leq i \leq r \).

We use the term *random polynomial* to represent a polynomial chosen uniformly at random from \( \mathcal{P}_d \). Note that we can obtain a random polynomial by choosing the coefficients of each monomial \( (X^i)^{\alpha_1}(X^j)^{\alpha_2} \cdots (X^l)^{\alpha_t} \) uniformly and independently from \( \mathbb{F}_q \). Since the constant term of a random polynomial is chosen uniformly from \( \mathbb{F}_q \), one can easily show that
\[
\mathbb{P}[f(v_1, v_2, \ldots, v_r) = 0] = \frac{1}{q}
\]
for a random polynomial \( f \) and any fixed \( r \)-tuple \( (v_1, v_2, \ldots, v_r) \).

In our constructions of random hypergraphs, the edges will appear when one polynomial or a system of polynomials vanishes, hence we can describe subhypergraphs as varieties. Let \( \mathbb{F}_q^{\text{alg}} \) be the algebraic closure of \( \mathbb{F}_q \), and we say that a variety is the set of common roots of a set of polynomials. Let \( W(\mathbb{F}_q) = W \cap \mathbb{F}_q \), and we say that \( W \) has complexity at most \( M \) if the above parameters \( s, t \) and the maximum degree of the polynomials are all bounded by \( M \).

Now we introduce two important lemmas which will be useful in our constructions. The first lemma is the key insight of the random algebraic construction, which provides very non-smooth probability distributions. While the second lemma will help us calculate the probability in certain situations.

**Lemma 2.1** ([7]). Suppose \( W \) and \( D \) are varieties over \( \mathbb{F}_q^{\text{alg}} \) of complexity at most \( M \) which are defined over \( \mathbb{F}_q \). Then either \( |W(\mathbb{F}_q) \setminus D(\mathbb{F}_q)| \leq c_M \) or \( |W(\mathbb{F}_q) \setminus D(\mathbb{F}_q)| = \frac{q^s}{2} \), where \( c_M \) depends only on \( M \).

**Lemma 2.2** ([25]). Given a set \( U \subseteq \binom{\mathbb{F}_q^t}{r} \), let \( V \subseteq \mathbb{F}_q^t \) be the set consisting of all points appeared as an element of an \( r \)-tuple in \( U \). Suppose that \( \binom{|U|}{2} < q \), \( \binom{|V|}{2} < q \) and \( |U| \leq d \). If \( f \) is a random polynomial chosen from \( \mathcal{P}_d \), then
\[
\mathbb{P}[f(u^1, u^2, \ldots, u^r) = 0, \forall \{u^1, u^2, \ldots, u^r\} \in U] = q^{-|U|}.
\]

### 3 Constructions of random multi-hypergraphs

In this section, we will show some lower bounds for \( \text{ex}_r(n, \mathcal{T}) \) via constructions of random multi-hypergraphs. Here we illustrate our main idea briefly. We first construct a random multi-hypergraph by taking union of \( h \) random hypergraphs. Our goal is to show that averagely this multi-hypergraph contains many edges, with very few copies of \( \mathcal{T} \) and multiple edges. Then we can use the deletion method to obtain a new hypergraph which is \( \mathcal{T} \)-free and has expected number of edges.
3.1 Complete $r$-partite $r$-uniform hypergraphs

In this subsection we consider the Turán number of complete $r$-partite $r$-uniform hypergraph $K_{s_1,s_2,...,s_r}^{(r)}$. We construct the random multi-hypergraph based on the construction of \[25\].

**Definition 3.1** ([25]). For given integers $s_1, s_2, \ldots, s_{r-1}$ and $r$, let $b = \prod_{i=1}^{r-1} s_i$, $t = \sum_{i=1}^{r-1} s_i$, $s = b(t-1) + 2$ and $d = bs$. Let $N = q^b$, we pick a symmetric polynomial $f$ from $\mathcal{P}_d$ uniformly at random. Then we define an $r$-uniform hypergraph $\mathcal{G}$ on $N$ vertices as following: the vertex set is a copy of $\mathbb{F}_q^b$, and the $r$-tuple \(\{v_1, v_2, \ldots, v_r\}\) forms an edge of $\mathcal{G}$ if and only if $f(v_1, v_2, \ldots, v_r) = 0$.

We pick $h$ independent random symmetric polynomials $f_1, f_2, \ldots, f_h$ from $\mathcal{P}_d$ uniformly, and denote their associated hypergraphs as $\mathcal{G}_1, \mathcal{G}_2, \ldots, \mathcal{G}_h$. Let $\mathcal{G}$ be a multi-hypergraph which is the union of $\mathcal{G}_1, \mathcal{G}_2, \ldots, \mathcal{G}_h$. In the multi-hypergraph $\mathcal{G}$, let $T$ be a fixed labelled copy of $K_{s_1,s_2,...,s_{r-1,1}}^{(r)}$ and denote its vertices as $u$ and $v_i^j$ for $1 \leq i \leq r-1$, $1 \leq j \leq s_i$ such that $v_1^1, v_1^2, \ldots, v_i^j$ are in the same specified part. Fix a sequence of vertices $w_1^i, w_2^i, \ldots, w_{s_i}^i$ for $1 \leq i \leq r-1$, and these vertices form $b$ distinct $(r-1)$-tuples according to the fixed labelled copy of $T$. Since every edge can be in one of $h$ distinct original hypergraphs $\mathcal{G}_k$, there are totally $h^b$ types of given labelled $T$. Let $p$ be a positive integer and $W$ be the family of copies of $T$ which contains the fixed sequence $w_1^i, w_2^i, \ldots, w_{s_i}^i$ in $\mathcal{G}$ for $1 \leq i \leq r-1$. We call a sequence of vertices $w_1^i, w_2^i, \ldots, w_{s_i}^i$ a $p$-bad sequence, if the corresponding set $W$ has size $|W| \geq p$. Let $B_p$ be the set of all $p$-bad sequences in $\mathcal{G}$.

**Lemma 3.2.** There exist constants $p$ and $C$ depending on $s_1, s_2, \ldots, s_{r-1}, r$ such that

$$\mathbb{E}[|B_{ph^b}|] \leq Ch^bN^{1-\frac{2}{r}}.$$

**Proof.** Fix a type $I \in [h]^b$, call a sequence of vertices $\{w_1^i, w_2^i, \ldots, w_{s_i}^i \mid 1 \leq i \leq r-1\}$ a $(p, I)$-bad sequence if the corresponding set $W_I$ has size $|W_I| \geq p$, where $p$ will be determined later. By the linearity of expectation, it suffices to prove that the expected number of $(p, I)$-bad sequences is $O(N^{1-\frac{2}{r}})$ since the total number of types is $h^b$.

Now we focus on the size of $W_I$. It is difficult to estimate $|W_I|$ directly, hence we consider the $s$-th moment of $|W_I|$. Note that $|W_I|^s$ counts the number of ordered collections of $s$ copies of $T$ from $W_I$, and these copies of $T$ may be the same, hence each member of such collections can be an element $P$ in

$$\mathcal{K} := \{K_{s_1,s_2,...,s_{r-1,1}}^{(r)}, K_{s_1,s_2,...,s_{r-1,2}}^{(r)}, \ldots, K_{s_1,s_2,...,s_{r-1,s}}^{(r)}\}.$$

For given $P \in \mathcal{K}$, let $N_s(P)$ be the number of all possible ordered collections of $s$ copies of $T \in W_I$ which appear in $\mathcal{G}$ as a copy of $P$. We use the following result in \[25\].

$$\mathbb{E}[|W|^s] = \sum_{P \in \mathcal{K}} N_s(P)q^{-e(P)} = O(1).$$
For a fixed type $I$, $W_I$ is a variety which consists of vertices $x \in \mathbb{F}_q^b$ satisfying the system of $b$ equations $f_k(w_{j_1}^1, w_{j_2}^2, \ldots, w_{j_{r-1}}^{r-1}, x) = 0$ for all $1 \leq i \leq r-1$ and $1 \leq j_i \leq s_i$, where the choice of $k$ for certain edge $(w_{j_1}^1, w_{j_2}^2, \ldots, w_{j_{r-1}}^{r-1}, x)$ only depends on the fixed type $I$. Note that every random polynomial $f_k(w_{j_1}^1, w_{j_2}^2, \ldots, w_{j_{r-1}}^{r-1}, x)$ is chosen from $\mathcal{P}_d$, we have that $W_I$ has complexity at most $bs$. By Lemma 2.1, either $|W_I| \leq c_I$ or $|W_I| \geq q^{2s}$. Then we can use the Markov’s inequality to bound the probability as

$$P[|W_I| \geq c_I] = P[|W_I| \geq \frac{q^2}{2}] = P[|W_I|^s \geq \left(\frac{q^2}{2}\right)^s] \leq \frac{E[|W_I|^s]}{\left(\frac{q^2}{2}\right)^s} = O(1).$$

Let $p = \max_{I \in [h^b]} c_I$, the expected number of $(p, I)$-bad sequences is at most $t!N^t \cdot \frac{O(1)}{q^s} = O(N^{1-\frac{s}{b}})$. By the linearity of expectation, Lemma 3.1 follows since the total number of types is $h^b$. $\square$

Now we are ready to prove our main result of complete $r$-partite $r$-uniform hypergraphs.

**Proof of Theorem 1.1** Let $\tilde{G}$ be the multi-hypergraph defined as above. It is easy to see the expected number of edges in $\tilde{G}$ is $h \frac{N^r}{q}$. Let $e_M$ be the number of multiple edges, we can bound the expected number of $e_M$ as

$$E[e_M] \leq \left(\frac{N}{r}\right)^h \sum_{i=2}^{h} \left(\frac{h}{i}\right) q^{-i} = O(N^{r-\frac{2}{b}}).$$

Moreover, by Lemma 3.2, the expected number of $ph^b$-bad sequences is at most $Ch^b N^{1-\frac{s}{b}}$. We regard all multiple edges as simple edges and remove one vertex from each $ph^b$-bad sequence to obtain a new hypergraph $\tilde{G'}$, since each vertex is contained in at most $O(N^{r-1})$ edges, hence the expected number of edges in $\tilde{G'}$ is at least

$$\frac{h}{q} \left(\frac{N}{r}\right) - \left(\frac{N}{r}\right)^h \sum_{i=2}^{h} \left(\frac{h}{i}\right) q^{-i} - O(N^{r-1})Ch^b N^{1-\frac{s}{b}}.$$

When $s_r$ is sufficiently large, we choose $h = \left(\frac{2s}{p}\right)^{\frac{1}{2}}$, then there exists a $K^{(r)}_{s_1, s_2, \ldots, s_r}$-free hypergraph with $\Omega(s_r^{\frac{r-1}{2}} n^{r-\frac{1}{2}})$ edges, the proof of Theorem 1.1 is finished. $\square$

### 3.2 Complete bipartite hypergraphs

In this subsection, we consider the Turán number of complete bipartite hypergraph $K^{(r)}_{s, t}$. Recall the definition of complete bipartite hypergraph as follows.
Definition 3.3 \([38]\). Let \(X_1, X_2, \ldots, X_t\) be \(t\) pairwise disjoint sets of size \(r - 1\), and let \(Y\) be a set of \(s\) elements, disjoint from \(\bigcup_{i\in[t]} X_i\). Then \(K_{s,t}^{(r)}\) denotes the complete bipartite \(r\)-uniform hypergraph with vertex set \((\bigcup_{i\in[t]} X_i) \cup Y\) and edge set \(\{X_i \cup \{y\} : i \in [t], y \in Y\}\).

We still take advantage of the construction in \([34]\).

Definition 3.4 \([34]\). For given integers \(t\) and \(r\), let \(N = q^t\), \(m = (r - 1)t^2 - t + 2\), and \(d = m\). \(r\). We pick a symmetric polynomial \(f\) from \(\mathcal{P}_d\) uniformly at random. Then we define an \(r\)-uniform hypergraph \(H\) on \(N\) vertices as following: the vertex set is a copy of \(\mathbb{F}_q^t\), and the \(r\)-tuple \(\{v_1, v_2, \ldots, v_r\} \in \binom{\mathbb{F}_q}{r}\) forms an edge of \(H\) if and only if \(f(v_1, v_2, \ldots, v_r) = 0\).

We then choose \(h\) independent random symmetric polynomials \(f_1, f_2, \ldots, f_h\) from \(\mathcal{P}_d\) uniformly, and denote their associated hypergraphs as \(H_1, H_2, \ldots, H_h\). Let \(\mathcal{H}\) be a multi-hypergraph which is the union of \(H_1, H_2, \ldots, H_h\). In the multi-hypergraph \(\mathcal{H}\), let \(R\) be a fixed labelled copy of \(K_{1,t}^{(r)}\), and we denote its vertices as \(a\) and \(u_i^1, u_i^2, \ldots, u_i^{r-1}\) for \(1 \leq j \leq t\) and \(i \in [r - 1]\) such that \(u_i^j, u_j^1, \ldots, u_j^{r-1}\) form \(t\) distinct \((r - 1)\)-tuples corresponding to the fixed labelled copy of \(R\). Since each edge of \(R\) can belong to one of \(h\) distinct original hypergraphs \(H_k\), there are in total \(h^t\) types of given labelled copy of \(R\). Now fix any sequence of vertices \(w_j^i\) for \(1 \leq j \leq t\) and \(i \in [r - 1]\) in \(\mathcal{H}\). Let \(W\) be the family of copies of \(R\) in \(\mathcal{H}\) such that \(w_j^i\) corresponds to \(u_j^i\) for all \(1 \leq j \leq t\) and \(i \in [r - 1]\). We say such a sequence \(p\)-bad if the corresponding set \(W\) satisfies \(|W| \geq p\). Let \(B_p\) be the set of all \(p\)-bad sequences in the multi-hypergraph \(\mathcal{H}\).

Lemma 3.5. There exist constants \(p = p(t, r)\) and \(C = C(t, r)\) such that

\[
\mathbb{E}[|B_{ph^t}|] \leq Ch^t q^{t-2}.
\]

Proof. Fix a type \(J \in [h]^t\), call a sequence of vertices \(\{w_j^1, w_j^2, \ldots, w_j^{r-1} : 1 \leq j \leq t\}\) a \((p, J)\)-bad sequence if the corresponding set \(W_J\) has cardinality \(|W_J| \geq p\) with \(p\) to be determined later. In the following we will prove that the expected number of \((p, J)\)-bad sequences is \(O(q^{t-2})\).

We prefer to bound the value of \(|W_j|^m\) rather than estimate \(|W_j|\) directly. Note that \(|W_j|^m\) counts the number of ordered collections of \(m\) copies of \(R\) from \(W_j\), where these copies of \(R\) may be identical. So each member of such collections can be an element \(L\) in

\[
\mathcal{L} := \{K_{1,t}^{(r)}, K_{2,t}^{(r)}, \ldots, K_{m,t}^{(r)}\}.
\]

For given \(L \in \mathcal{L}\), denote \(N_m(L)\) as the total number of all possible ordered collections of \(m\) copies of \(R \in W_j\), which could appear in \(\mathcal{H}\) as a copy of \(L\). We use the following result in \([34]\),

\[
\mathbb{E}[|W_J|^m] = \sum_{L \in \mathcal{L}} N_m(L) q^{-e(L)} = \sum_{L \in \mathcal{L}} O(q^{t(|L| - t(r - 1)))q^{-e(L)} = O(1).
\]
Note that \( W_J \) is a variety which consists of vertices \( x \in \mathbb{F}_q^t \) satisfying the system of \( t \) equations
\[
f_k(w_j^1, w_j^2, \ldots, w_j^{r-1}, x) = 0
\]
for \( 1 \leq j \leq t \). The choice of \( k \) is depended on the fixed type \( J \), and \( f_k \) is the random polynomial used to define random hypergraph \( \mathcal{H}_k \). It is easy to check that for each \( k \in [h] \), the random polynomial \( f_k(w_j^1, w_j^2, \ldots, w_j^{r-1}, x) \) has degree at most \( d \), hence the variety \( W_J \) has complexity at most \( d \).

Then by Lemma 2.1, either \( |W_J| \leq c_J \) or \( |W_J| \geq \frac{q}{2} \), where \( c_J \) is depended on \( d \) and the type \( J \).

With the Markov’s inequality, we obtain that
\[
P(|W_J| \geq c_J) = P(|W_J| \geq \frac{q}{2}) = P(|W_J|^m \geq (\frac{q}{2})^m) \leq \frac{\mathbb{E}[|W_J|^m]}{(\frac{q}{2})^m} = O(1).
\]

Set \( p = \max_{J \in [h]^t} c_J \), the expected number of \((p, J)\)-bad sequences is at most \((t(r-1))!N^{t(r-1)} \cdot \frac{O(1)}{q^m} = O(q^{-2})\). Since the number of types \( J \in [h]^t \) is \( h^t \), then Lemma 3.5 follows by the linearity of expectation.

Now we are ready to prove the main result of complete bipartite hypergraphs.

**Proof of Theorem 1.2** Let \( \mathcal{H} \) be the random multi-hypergraph defined as above. Then by Lemma 2.2, the expected number of edges in \( \mathcal{H} \) is \( \frac{h}{q} \binom{N}{r} \). Let \( e_M \) be the number of multiple edges, we can bound the expected number of \( e_M \) as
\[
\mathbb{E}[e_M] \leq \binom{N}{r} \sum_{i=2}^{h} \binom{h}{i} q^{-i} = O(N^{r - \frac{2}{7}}).
\]

As we have shown in Lemma 3.5, the expected number of \( ph^t \)-bad sequences is at most \( Ch^t q^{-2} \). We regard all multiple edges as simple edges and remove a vertex from each \( ph^t \)-bad sequence to obtain a new hypergraph \( \mathcal{H}' \), since each vertex is contained in at most \( O(N^{r-1}) \) edges, hence the expected number of edges in \( \mathcal{H}' \) is at least
\[
\frac{h}{q} \binom{N}{r} - \binom{N}{r} \sum_{i=2}^{h} \binom{h}{i} q^{-i} - O(N^{r-1})Ch^t q^{-2}.
\]

When \( s \) is sufficiently large, let \( h = (\frac{1}{p})^{\frac{1}{7}} \), then there exists a \( K_{s,t}^{(r)} \)-free hypergraph with \( \Omega(s^{\frac{1}{7}}n^{r-\frac{1}{7}}) \) edges. The proof of Theorem 1.2 is finished.
3.3 Berge theta hypergraphs

Now we define a random hypergraph model that we will use in our construction.

**Definition 3.6.** For given integers $r$ and $\ell$, let $d = r\ell^2$ and $N = q^\ell$, we pick $\ell(r - 1) - 1$ symmetric polynomials $f_1, f_2, \ldots, f_{\ell(r-1)-1}$ from $P_d$ uniformly at random. Let $F$ be an $r$-partite $r$-uniform hypergraph $\mathcal{F}$ on $rN$ vertices as following: the vertex set $V(\mathcal{F}) = \{V_1, V_2, \ldots, V_r\}$ is $r$ distinct copies of $F$, and for $v_i \in V_i$, $1 \leq i \leq r$, the $r$-tuple $\{v_1, v_2, \ldots, v_r\}$ forms an edge of $\mathcal{F}$ if and only if

$$f_1(v_1, v_2, \ldots, v_r) = f_2(v_1, v_2, \ldots, v_r) = \cdots = f_{\ell(r-1)-1}(v_1, v_2, \ldots, v_r) = 0.$$

We pick $h$ random hypergraphs $\mathcal{F}_1, \mathcal{F}_2, \ldots, \mathcal{F}_h$ independently and let $\bar{\mathcal{F}}$ be a multi-hypergraph which is the union of the $\mathcal{F}_i$. For the random multi-hypergraph $\bar{\mathcal{F}}$ and positive integer $p$, we say that a pair of vertices $x, y$ is $p$-bad if there are at least $p$ Berge paths of length at most $\ell$ between $x$ and $y$. Now we need to bound the number of $ph^\ell$-bad pairs in $\bar{\mathcal{F}}$.

**Lemma 3.7.** Let $B_{ph^\ell}$ be the set of all $ph^\ell$-bad pairs in $\bar{\mathcal{F}}$, there exist constants $p = p(r, \ell)$ and $C = C(r, \ell)$ such that

$$\mathbb{E}(|B_{ph^\ell}|) \leq Ch^\ell q^{\ell(2-r)}.$$

**Proof.** Let $\ell_0 \leq \ell$ be an integer and $K = (k_1, k_2, \ldots, k_{\ell_0}) \in [h]^{\ell_0}$ be a fixed type. A Berge path made of edges $e_1, e_2, \ldots, e_{\ell_0}$ is of type $(k_1, k_2, \ldots, k_{\ell_0})$ if $e_j \in E(\mathcal{F}_j)$ for $1 \leq j \leq \ell_0$. For some fixed type $K = (k_1, k_2, \ldots, k_{\ell_0}) \in [h]^{\ell_0}$, we say that a pair of vertices $x, y$ is $(p, K)$-bad if there are at least $p$ Berge paths of type $K$ between $x$ and $y$. Since the total number of types is $\sum_{\ell_0 \leq \ell} h^{\ell_0} \leq \ell h^\ell$, we then show that for each fixed type $K$, there is a constant $p = p(r, \ell)$ such that the expected number of $(\frac{p}{r}, K)$-bad pairs is $O_{r, \ell}(q^{\ell(2-r)})$.

The first step is to estimate the expected number of short Berge paths between pairs of vertices. Let $x$ and $y$ be fixed vertices in $\mathcal{F}$ and $K = (k_1, k_2, \ldots, k_{\ell_0})$ be a fixed type. Denote $S_K$ as the set of Berge paths of type $K$ between $x$ and $y$. It is difficult to estimate $|S_K|$ directly, hence we consider the value of $|S_K|^{r^\ell}$, which counts the number of ordered collections of $r^\ell$ Berge paths of type $K$ from $x$ to $y$. Let $P_{\ell_0, m}$ be the number of collections of Berge paths between $x$ and $y$ such that their intersection has $m$ edges, then we have

$$\mathbb{E}(|S_K|^{r^\ell}) = \sum_{m=1}^{r^\ell^2} P_{\ell_0, m} q^{m(1-\ell(r-1))}.$$

We use the argument of He and Tait [20], which showed that

$$P_{\ell_0, m} = O_{\ell_0, r}(q^{m(\ell_0(r-1)-1)}).$$
Hence we obtain that
\[ \mathbb{E}[|S_K|^\ell] = \sum_{m=1}^{r^2} P_{\ell_0,m} q^{m(1-\ell(r-1))} \leq \sum_{m=1}^{r^2} 1 = C_K, \]
where the last inequality holds since \( \ell_0 \leq \ell \).

In the next step, we will show that \( |S_K| \) is either bounded by some constant or is at least \( \frac{2}{q} \). However there is no fixed set of polynomials whose set of common roots is exactly \( S_K \), hence it is difficult to write \( S_K \) as a variety directly. We need to analyze the set \( S_K \) as follows.

By the definition of Berge path, each Berge path of length \( \ell_0 \) in \( S_K \) is a sequence of core vertices and edges such as \( (x, e_1, v_1, e_2, \ldots, v_{\ell_0-1}, e_{\ell_0}, y) \). We can partition the set of Berge paths into which partite set each core vertex \( v_i \) is in. Hence for fixed type \( K \), \( S_K \) can be partitioned into disjoint sets depending on which partite set each core vertex belongs to. Denote \( S_{t_1,t_2,\ldots,t_{\ell_0-1}} \) as the set of Berge paths from \( x \) to \( y \) such that the \( i \)-th core vertex \( v_i \in V_{t_i} \). If we view \( \sigma \) as \( \ell_0-1 \) tuple from \( [r]^{\ell_0-1} \), then we can write \( S_K \) as
\[ S_K = \bigcup_{\sigma \in [r]^{\ell_0-1}} S_{K,\sigma}, \]
and obviously it is a disjoint union.

Fix any \( S_{K,\sigma} \), we denote the core vertices in an arbitrary Berge path of length \( \ell_0 \) as \( v_1, v_2, \ldots, v_{\ell_0-1} \) and the non-core vertices in edge \( e_j \) as \( w_{k_j}^1, w_{k_j}^2, \ldots, w_{k_j}^{k_j-2} \), where edge \( e_j \) is in \( F_{k_j} \). Here we need to make sure that the non-core vertices are ordered based on their partite sets, that is, if \( w_{s_1}^1 \in V_{t_1} \) and \( w_{s_2}^2 \in V_{t_2} \), where \( s_1 < s_2 \), then \( t_1 < t_2 \).

Now we define the variety \( T_{K,\sigma} \) as
\[ \{ z \in \mathbb{F}_q^{\ell_0(r-1)-1} : f_{i_{1,1}}^{k_1} (z) = f_{i_{1,2}}^{k_2} (z) = \cdots = f_{i_{1,\ell_0}}^{k_{\ell_0}} (z) = 0, 1 \leq i \leq \ell_0 (r-1) - 1 \}, \]
where \( f_{i,j}^{k} \) is the \( j \)-th random polynomial used to define \( F_{k_j} \) and \( z \in \mathbb{F}_q^{\ell_0(r-1)-1} \) runs over sequence \( (v_1, \ldots, v_{\ell_0-1}, w_1^1, \ldots, w_{r_1}^{k_1}, \ldots, w_1^{k_1}, \ldots, w_{r_2}^{k_2}, \ldots, w_{r_1}^{k_0}, \ldots, w_{r_{\ell_0}}^{k_{\ell_0}}) \). Note that each \( z \) is a vector ordered with the core vertices first and the non-core vertices after.

We then write the polynomials \( f_{i_{1,1}}^{k_1} (z) = f_{i_{1,2}}^{k_2} (z) = \cdots = f_{i_{1,\ell_0}}^{k_{\ell_0}} (z) \) more accurately as follows.
\[ f_{i_{1,1}}^{k_1} (z) = f_{i_{1}}^{k_1} (x, v_1, w_1^{k_1}, \ldots, w_{r_1}^{k_1}), \]
\[ f_{i_{1,2}}^{k_2} (z) = f_{i_{1}}^{k_2} (x, v_1, w_1^{k_2}, \ldots, w_{r_2}^{k_2}), \]
\[ \cdots \]
\[ f_{i_{1,\ell_0}}^{k_{\ell_0}} (z) = f_{i_{1}}^{k_{\ell_0}} (u_{\ell_0-1}, y, w_1^{k_0}, \ldots, w_{r_2}^{k_0}). \]
where $1 \leq i \leq \ell_0(r-1) - 1$. Observe that when $\sigma$ is fixed, the order of all non-core vertices is fixed, hence we also fix the order of arguments given to $f_{i}^{k_{i_0}}$ according to $\sigma$. For example, suppose $v_{\ell_0-1} \in V_1$ and $y \in V_3$, then we write $f_{i,\ell_0}^{k_{i_0}}(z)$ as

$$f_{i,\ell_0}^{k_{i_0}}(z) = f_{i}^{k_{i_0}}(v_{\ell_0-1}, w_1^{k_{i_0}}, y, w_2^{k_{i_0}}, \ldots, w_{r-2}^{k_{i_0}}).$$

It is easy to see that $S_{K,\sigma} \subset T_{K,\sigma}$. However $T_{K,\sigma}$ contains not only all the Berge paths in $S_{K,\sigma}$ but also some degenerate walks which are not Berge paths, hence to obtain $S_{K,\sigma}$ we need to exclude the walks that are not Berge paths. If $T_{K,\sigma}$ contains a degenerate walk $x = v_0, v_1, v_2, \ldots, v_{\ell_0-1}, v_{\ell_0} = y$, define

$$D_{a,b} \triangleq T_{K,\sigma} \cap \{v_0, \ldots, v_{\ell_0}, w_1^{k_1}, \ldots, w_{r-2}^{k_{r-2}} : v_a = v_b\},$$

for $0 \leq a < b \leq \ell_0$ and let $D \triangleq \bigcup_{a,b} D_{a,b}$. We claim that $D$ is a variety since the union of varieties is a variety, and the complexity of $D$ is bounded.

Now we can use Lemma 2.1 to analyze $S_{K,\sigma} = T_{K,\sigma} \setminus D$. For arbitrary type $K$ and $\sigma \in [v]^{\ell_0-1}$, there exists a constant $c(K, \sigma)$ which is depended on $K$ and $\sigma$, such that either $|S_{K,\sigma}| \leq c(K, \sigma)$ or $|S_{K,\sigma}| \geq \frac{q}{2}$. Note that $|S_K| = \sum_{\sigma \in [v]^{\ell_0-1}} |S_{K,\sigma}|$, if there exists a $\sigma$ such that $|S_{K,\sigma}| > c(K, \sigma)$, then $|S_K| \geq |S_{K,\sigma}| \geq \frac{q}{2}$, otherwise $|S_K| \leq c(K, \ell_0, r)$ for some constant $c(K, \ell_0, r)$ which is depended on $\ell_0$ and $r$. With the Markov’s inequality, we obtain that

$$\mathbb{P}[|S_K| \geq c(K, \ell_0, r)] = \mathbb{P}[|S_K| \geq \frac{q}{2}] = \mathbb{P}[|S_K|^r \geq \left(\frac{q}{2}\right)^r] \leq \frac{\mathbb{E}(|S_K|^r)}{\left(\frac{q}{2}\right)^r} = \frac{C_K}{\left(\frac{q}{2}\right)^r} = O_{r,\ell}(q^{-r}).$$

Let $p \triangleq \ell \max_{\ell_0 \leq \ell} c(K, \ell_0, r)$, then we have the expected number of $(\frac{q}{2}, K)$-bad pairs is at most $(rN)^2 \frac{C_K}{\left(\frac{q}{2}\right)^r} = O_{r,\ell}(q^{(2-r)})$. The proof of Lemma 3.7 is finished by linearity of expectation.

**Proof of Theorem 1.5** When $\ell \geq 2$, let $\bar{F}$ be a multi-hypergraph defined as above. By Lemma 3.7, there are constants $p = p(r, \ell)$ and $C = C(r, \ell)$ such that the expected number of $ph^{r}$-bad pairs is at most $C h^{\ell}q^{(2-r)}$. Let $F$ be obtained from $\bar{F}$ by transforming all the multiple edges to simple edges.

Since $\mathcal{F}_1, \mathcal{F}_2, \ldots, \mathcal{F}_h$ are independent random hypergraphs, by Lemma 2.2, the expected number of edges in $\bar{F}$ is $h^{\ell+1} = h^{\ell}q^{\ell+1}$ and $Y$ is the number of multiple edges, we can bound its expected number as following

$$\mathbb{E}[Y] \leq N^r \sum_{i=2}^{h} \binom{h}{i} \frac{1}{q^{(r-1)}-1} = o(N).$$
Then we can remove all $ph^\ell$-bad pairs in $\mathcal{F}$ to obtain a new hypergraph $\mathcal{F}'$. Since each vertex is in at most $O(n^{r-1})$ edges, at most $O(n^{r-1})|B_{ph^\ell}|$ edges are removed. Therefore the expected number of edges in $\mathcal{F}'$ is at least

$$\mathbb{E}[e(\mathcal{F}')] \geq h(\frac{N}{r})^{1+\frac{1}{\ell}} - 2N^{r-1}\mathbb{E}[|B_{ph^\ell}|] - N^r \sum_{i=2}^{h} \binom{h}{i} \left( \frac{1}{q^{(r-1)-1}} \right)^i.$$

When $t$ is sufficiently large, let $h = (\frac{1}{\rho})^{\frac{1}{\ell}}$, then there exists a hypergraph $\mathcal{F}'$ which is $\Theta_{\ell,t}^B$-free with $\Theta(n)$ vertices and $\Omega_{r,\ell}(t^{\frac{1}{\ell}}n^{1+\frac{1}{\ell}})$ edges.

\[ \Box \]

4 Concluding remarks

In this paper, we develop the powerful random algebraic method to construct various multi-hypergraphs. We investigate three important objects including complete $r$-partite $r$-uniform hypergraphs, complete bipartite hypergraphs and Berge theta hypergraphs, and we obtain some tight lower bounds on the corresponding Turán problems.

However, we fail in determining whether the upper bound $\text{ex}_r(n, \Theta^B_{\ell,t}) = O_{\ell,t}(t^{r-1-\frac{1}{\ell}}n^{1+\frac{1}{\ell}})$ is tight when $t$ is large. We strongly believe this upper bound is tight, for instance, the results of Gerbner, Methuku and Vizer \[16\] determined the asymptotics for $\text{ex}_3(n, \Theta^B_{2,t}) = (1 + o(1))(\frac{1}{6}(t - 1)\frac{1}{2}n^{\frac{2}{3}}$. Moreover, for some relatively small $\ell$ and $t$, determining $\text{ex}_r(n, \Theta^B_{\ell,t})$ is also of great interest.
