STOCHASTIC SOLUTIONS FOR TIME-FRACTIONAL HEAT EQUATIONS WITH COMPLEX SPATIAL VARIABLES

LUISA BEGHIN AND ALESSANDRO DE GREGORIO

Abstract. We deal with complex spatial diffusion equations with time-fractional derivative and study their stochastic solutions. In particular, we complexify the integral operator solution to the heat-type equation where the time derivative is replaced with the convolution-type generalization of the regularized Caputo derivative. We prove that this operator is solution of a complex time-fractional heat equation with complex spatial variable. This approach leads to a wrapped Brownian motion on a circle time-changed by the inverse of the related subordinator. This time-changed Brownian motion is analyzed and, in particular, some results on its moments, as well as its construction as weak limit of continuous-time random walks, are obtained. The extension of our approach to the higher dimensional case is also provided.

MSC 2010: Primary 26A33; Secondary 60G22

Key Words and Phrases: complex singular integrals, complex evolution equations, generalized Caputo derivative, time-changed processes, wrapped Brownian motion

1. Introduction

The study of the evolution equations with complex spatial variables is a quite recent research topic in the theory of the partial differential equations and complex analysis. In the pioneering works [8]-[9], the authors proposed two different methods to complexify the spatial variable appearing in different evolution equations (and keeping the time variable real). In particular, for the heat equation a possible approach consists in the complexification of the spatial variable in the linear semigroup operator

\[ T_t f(x) = \frac{1}{\sqrt{2\pi t}} \int_{-\infty}^{+\infty} f(x-y) e^{-\frac{y^2}{2t}} dy \]

representing the unique solution to the Cauchy problem

\[ \frac{\partial u}{\partial t}(x,t) = \frac{1}{2} \frac{\partial^2 u}{\partial x^2}(x,t), \quad u(x,0) = f(x), \]

where \( t > 0, x \in \mathbb{R} \) and \( f \in \text{BUC}(\mathbb{R}) \). This approach is interesting because, by exploiting the theory of semigroups of linear operators, it is possible to obtain a new complex version of the heat equation (see (2.2) below) and study the properties of its analytic solution (see [8]-[9]). Furthermore, it is worth to observe that in this framework a suitable probabilistic interpretation of the solution to (2.2) leads to a wrapped up Brownian motion on a circle. The stochastic analysis of complex diffusion equations still seems to be an unexplored research topic.

The above mentioned theory was developed starting from partial differential equations involving the standard time derivative. The aim of this paper is to study complex versions of the time-fractional heat equations obtained by complexifying the spatial variable only (and keeping the time variable real). The main idea is to complexify the spatial variable in the corresponding...
integral operator arising in the study of time-fractional evolution equations. In particular, we study the stochastic solution of the complex heat equation, when the time-derivative is replaced by a convolution-type operator, which generalizes the Caputo fractional derivative. We will adopt the definition given in [6], i.e.

\begin{equation}
\mathcal{D}_t^\alpha u(t) := \frac{d}{dt} \int_0^t (t - s)^{-\alpha}(u(s) - u(0))ds, \quad t \geq 0,
\end{equation}

where \(w(\cdot)\) is the tail Lévy measure of a subordinator \(\mathcal{H}_\theta := \{\mathcal{H}_\theta(t)\}_{t \geq 0}\) and \(g(\cdot)\) is its Laplace exponent, i.e. \(E e^{-\theta \mathcal{H}_\theta(t)} = e^{-\theta g(t)}\), where \(t, \theta \geq 0\) (see Section 3 for details on this definition). The so-called generalized fractional calculus has been developed in recent years, starting from Kochubei in [13], by many authors (see, among the others, [23], [10], [14]). They extend the traditional construct of fractional derivatives and integrals in order to allow a wider class of kernels. Indeed, it is immediate to check that, by choosing \(w(\cdot) = \delta_{1/2}\), \(g(\cdot) = 2\), traditional construct of fractional derivatives and integrals in order to allow a wider class of kernels. Indeed, it is immediate to check that, by choosing \(w(\cdot) = \delta_{1/2}\), \(g(\cdot) = 2\),

\begin{equation}
\frac{\partial^\alpha}{\partial t^\alpha} u(t) := \frac{1}{\Gamma(1 - \alpha)} \frac{d}{dt} \int_0^t (t - s)^{-\alpha}(u(s) - u(0))ds, \quad t \geq 0.
\end{equation}

It has been proved in [17] that the solution to

\[ \frac{\partial^\alpha}{\partial t^\alpha} u(x,t) = \Delta u(x,t), \quad t \geq 0, \quad x \in \mathbb{R}^d, d \geq 1, \]

with \(u(x,0) = f(x)\), admits the probabilistic representation \(E_x [f(B(\mathcal{H}_\alpha(t)))]\), where \(B := \{B(t)\}_{t \geq 0}\) is the standard Brownian motion on \(\mathbb{R}^d\), with infinitesimal generator \(\Delta\), and \(\mathcal{E}_\alpha := \{\mathcal{E}_\alpha(t)\}_{t \geq 0}\), is the inverse of the stable subordinator \(\mathcal{H}_\alpha\) (independent of \(B\)).

The paper is organized as follows. Section 2 contains the probabilistic interpretation of the solution to the complex Cauchy problem introduced in [8] and a discussion on the properties of the circular Brownian motion. The generalized fractional setting and the complex time-fractional heat equation are introduced in Section 3, where the stochastic solution related to the related complex Cauchy problem is obtained. Section 4 is devoted to the analysis of the time-changed Brownian motion emerging in the previous section. Some results on the moments of the process are provided, as well as the construction of the time-changed process based on the convergence of time-continuous random walks. Furthermore, some special cases involving stable and tempered
stable subordinators are examined. The last section contains the analysis of the complex time-
fractional heat equation in higher dimensions.

2. On the probabilistic meaning of heat-type equations with complex space
variables

Let $D := \{ z \in \mathbb{C}; |z| < 1 \}$ be the open unit disk and introduce the Banach space $(A(D), \| \cdot \|)$, where $A(D) = \{ f : D \to \mathbb{C} : f$ is analytic on $D$, continuous on $\overline{D} \}$, endowed with the uniform norm $\| f \| = \sup \{|f|; z \in D\}$. If $f \in A(D)$ then it can be represented in the series form $f(z) = \sum_{k=0}^{\infty} a_k z^k$.

In the interesting paper [8], it was proved (see Theorem 2.1 in [8]) that the singular (at $t = 0$) complexified Cauchy problem in this way. Indeed, it is evident from (2.1), that the solution of

\begin{equation}
W_t f(z) = \frac{1}{\sqrt{2\pi t}} \int_{-\infty}^{+\infty} f(ze^{-iu})e^{-u^2/2t} du, \quad t \geq 0,
\end{equation}

is a $C_0$-contraction semigroup of linear operators on $A(D)$. Furthermore, $u(z, t) = W_t f(z)$, is the unique solution (with $u(z, t) \in A(D)$ for a fixed $t$) for the Cauchy problem

\begin{equation}
\frac{\partial u}{\partial t}(z, t) = \frac{1}{2} \frac{\partial^2 u}{\partial \varphi^2}(z, t), \quad z = re^{i\varphi}, 0 < r < 1, \varphi \in [0, 2\pi),
\end{equation}

under the initial condition

\begin{equation}
u(z, 0) = f(z), \quad z \in \overline{D},
\end{equation}

where $f \in A(D)$.

Here we briefly discuss the interesting probabilistic meaning of representing the solution of a
complexified Cauchy problem in this way. Indeed, it is evident from (2.1), that the solution of the latter can be expressed as

\begin{equation}
u(z, t) = \mathbb{E} f \left( ze^{-iB(t)} \right) = \mathbb{E} f (\mathcal{B}_z(t)),
\end{equation}

where $B := \{ B(t) \}_{t \geq 0}$ is the $\mathbb{R}$-valued Brownian motion on $(\Omega, \mathcal{F}, \mathbb{P})$ and $\mathcal{B}_z(t) = z e^{-iB(t)}$. This means that the probabilistic representation of the solution for this complexified Cauchy problem is directly related to a circular or wrapped Brownian motion $\mathcal{B}_z := \{ \mathcal{B}_z(t) \}_{t \geq 0}$ moving on a circle with radius $r \in (0, 1]$ (hereafter denoted by $\mathcal{S}_r$) and starting point $z$. Furthermore, $\mathcal{B}_z$ stands for $\mathcal{B}_1$.

For the sake of simplicity, we set $z = 1$. From the properties of the classical $\mathbb{R}$-valued Brownian motion, it is easy to characterized $\mathcal{B}$. Let $\overline{\mathcal{B}}$ be the complex conjugate of $\mathcal{B}$. We observe that the wrapped Brownian motion $\mathcal{B}$, satisfies the following properties:

1) $\mathcal{B}(0) = 1$ a.s.;
2) $\mathcal{B}(t_k)\overline{\mathcal{B}}(t_{k-1})$ with $k = 1, 2, ..., n \in \mathbb{N}, 0 = t_0 < t_1 < t_2 < ... < t_n < \infty$ are independent;
3) $\mathcal{B}(t)\overline{\mathcal{B}}(s)$ has the same distribution of $\mathcal{B}(t+h)\overline{\mathcal{B}}(s+h)$, where $0 \leq s < t, h \geq -s$;
4) for $0 \leq s \leq t$,

\begin{equation}
\mathcal{B}(t)\overline{\mathcal{B}}(s) \sim WN(0, e^{-\frac{t-s}{\sigma^2}}),
\end{equation}

where $WN(\mu, e^{-\frac{\sigma^2}{2}}), \mu \in \mathbb{R}, \sigma^2 > 0$, stands for a wrapped normal random variables with probability density function given by

\begin{equation}f(\varphi) = \frac{1}{\sqrt{2\pi \sigma}} \sum_{k=-\infty}^{\infty} e^{-\frac{(\varphi - \mu + 2k \pi)^2}{2\sigma^2}}, \quad \varphi \in [0, 2\pi).
\end{equation}

This result follows by standard arguments on the wrapped distributions; i.e. by wrapping the $N(0, t-s)$ onto the circle (see, e.g., [16]).
5) $\mathfrak{B}$ is a wrapped Gaussian process; i.e. let $0 =: t_0 \leq t_1 < t_2 < \ldots < t_n < \infty$, the random vector $(\mathfrak{B}(t_1), \mathfrak{B}(t_2), \ldots, \mathfrak{B}(t_n))$ is multivariate wrapped normal in the following sense

$$\prod_{k=1}^{n} (\mathfrak{B}(t_k))^{\alpha_k}, \quad \alpha_k \in \mathbb{R},$$

admits a one-dimensional wrapped gaussian distribution. Indeed,

$$\prod_{k=1}^{n} (\mathfrak{B}(t_k))^{\alpha_k} = e^{i \sum_{k=1}^{n} \alpha_k B(t_k)}.$$

Since $B$ is a Gaussian process, it follows that

$$n \sum_{k=1}^{n} \alpha_k B(t_k) \sim N(0, \sum_{k=1}^{n} \alpha_k^2 t_k).$$

Then, as in the previous point

$$\prod_{k=1}^{n} (\mathfrak{B}(t_k))^{\alpha_k} \sim WN(0, e^{-\sum_{k=1}^{n} \alpha_k^2 t_k}).$$

3. Time-fractional diffusive-type equations with a complex spatial variable

Let us introduce a time-fractional version of the complex heat equation (2.2) and study its stochastic solution.

Let $g : (0, +\infty) \to \mathbb{R}$ be a Bernstein function (i.e. a non-negative, $C^\infty$ function such that $(-1)^{k-1} g^{(k)}(x) \leq 0, \forall x > 0, k \in \mathbb{N}$). Then, it is well-known that the following representation holds (see e.g., [22])

$$g(x) = a + bx + \int_{0}^{\infty} (1 - e^{-sz}) \nu(ds), \quad b \geq 0,$$

where $\nu(\cdot)$ is a non-negative measure on $(0, +\infty)$, satisfying the condition

$$\int_{0}^{\infty} (z \land 1) \nu(dz) < \infty,$$

i.e. $\nu$ is a Lévy measure.

Let $w(s) = \int_{0}^{\infty} \nu(dz)$ be its tail, in this paper we consider the following convolution-type derivative (see [6])

$$\mathfrak{D}^\alpha u(t) := \frac{d}{dt} \int_{0}^{t} w(t - s) (u(s) - u(0))ds.$$

Typically $w$ is a non-negative decreasing function on $(0, +\infty)$ that blows up at $x = 0$ and locally integrable on $[0, \infty)$. We refer to [6] for the functional setting, observing that obviously this definition is a generalization of the Caputo fractional derivative (see, e.g., [12]): the latter is recovered, as a special case, for $w(s) = \frac{s^\alpha}{\Gamma(1-\alpha)}$, with $\alpha \in (0, 1)$. Observe that we used a quite different notation from [6] in order to underline the connection between this generalized fractional derivative and the particular choice of the underlying Bernstein function $g$. We remark that a similar probabilistic approach to the generalized time-fractional derivatives have been developed in [23]. It is similar but not equivalent. Hereafter, we exclude compound Poisson subordinator, namely we assume that $a = 0$ and that the tail measure $w(\cdot)$ is infinite in the origin and absolutely continuous on $(0, +\infty)$. Let now $H_g := \{H_g(t)\}_{t \geq 0}$ be the subordinator with Lévy measure $\nu$ and Laplace exponent $g$, i.e.

$$\mathbb{E} \left( e^{-\theta H_g(t)} \right) = e^{-tg(\theta)}, \quad \theta \geq 0.$$
We denote by \( E_g := \{ E_g(t) \}_{t \geq 0} \), the inverse (or hitting-time) process \( E_g(t) := \inf \{ s > 0 : H_g(s) > t \} \), i.e.
\[
\begin{align*}
\{ E_g(t) \geq s \} = \{ H_g(s) \leq t \}, \quad \forall s, t \in \mathbb{R}^+.
\end{align*}
\]
By the assumptions on \( w \), the subordinator \( t \mapsto H_g(t) \) associated to \( g \) is strictly increasing a.s. As a consequence, its inverse \( t \mapsto E_g(t) \) is continuous a.s. We recall that the time-Laplace transform of the density of \( E_g(t) \) denoted by \( m_g(s, t) := \mathbb{P}(E_g(t) \in ds) / ds \) reads
\[
\int_0^\infty e^{-\theta t} m_g(s, t) dt = \frac{g(\theta)}{\theta} e^{-sg(\theta)}, \quad \theta \geq 0,
\]
see, for example, Proposition 3.2 in [23].

We now consider the standard \( \mathbb{R} \)-valued Brownian motion \( B(t) \), time-changed by \( E_g(t) \), \( t \geq 0 \), (under the assumption that \( B \) and \( E_g \) are mutually independent); i.e. \( \{ B(E_g(t)) \}_{t \geq 0} \). Then, the density of \( B(E_g(t)) \) for a fixed \( t > 0 \), is given by
\[
\ell_g(x, t) = \int_0^{+\infty} e^{-\frac{x^2}{2t}} m_g(y, t) dy, \quad x \in \mathbb{R}.
\]

For all \( t > 0 \), we can define on \( D \), the following complex integral
\[
W_t^g f(z) := \int_{\mathbb{R}} f(z e^{-iu}) \ell_g(u, t) du, \quad z \in \overline{D},
\]
where \( \ell_g \) is given in (3.6). The following stochastic interpretation of (3.7) emerges
\[
W_t^g f(z) = E f(\mathfrak{B}_g^z(t)),
\]
where
\[
\mathfrak{B}_g^z := \{ \mathfrak{B}_g^z(t) \}_{t \geq 0} := \{ z e^{-iB(t)} \}_{t \geq 0},
\]
is the time-changed circular Brownian motion moving on a circle with radius \( r \in (0, 1] \) with starting point \( z \), obtained from the wrapped up process \( \mathfrak{B}_g^z \) introduced in the previous section.

We observe that
\[
W_t^g f(z) = E [W_{E_g(t)} f(z)] = \int_0^\infty W_y f(z) m_g(y, t) dy,
\]
that is \( W_t^g \) arises by the time-change of the \( C_0 \)-semigroup (2.1).

We have the following analytic results concerning the convolution operator \( W_t^g \).

**Theorem 3.1.** (i) If \( f \in A(D) \), then we have that for any \( t > 0 \), we have that
\[
W_t^g : A(D) \to A(D);
\]
i.e. \( W_t^g f(z) \) is analytic in \( D \)
\[
W_t^g f(z) = \sum_{k=0}^{\infty} a_k z^k d_k(t),
\]
where \( d_k(t) := E[e^{-\frac{i\theta t}{\sqrt{2}}} \mathfrak{B}_g(t)] \), and if \( f \) is continuous on \( \overline{D} \), the integral \( W_t^g f(z) \) is continuous on \( \overline{D} \) as well. Furthermore
\[
R_\theta W_t^g f(z) := \int_0^\infty e^{-\theta t} W_t^g f(z) dt = \sum_{k=0}^{\infty} a_k z^k \tilde{d}_k(\theta), \quad \theta \geq 0,
\]
where
\[
\tilde{d}_k(\theta) := \frac{g(\theta) / \theta}{g(\theta) + \frac{\pi}{2}}.
\]
(ii) Moreover, \( u(z, t) = W_t^b f(z) \) is the unique solution, belonging to \( A(D) \) for any \( t \geq 0 \), of the Cauchy problem

\[
\begin{align*}
(D_t^b + \beta \partial_t) u(z, t) &= \frac{1}{2} \frac{\partial^2 u}{\partial z^2}(z, t), \quad (t, z) \in (0, \infty) \times D \setminus \{0\}, \ z = re^{i\varphi},
\end{align*}
\]

(3.12)

\[
\begin{align*}
\quad u(z, 0) &= f(z), \quad f(z) \in A(D), \ z \in \overline{D}.
\end{align*}
\]

(3.13)

\[ L \left( D_t^b W_t^b f(z) + b \frac{\partial}{\partial t} W_t^b f(z); \theta \right) = g(\theta) R_b W_t^b f(z) - \frac{g(\theta)}{\theta} f(z) \]

Proof. (i) The representation (3.10) follows by considering that \( f(z) \in A(D) \) and by taking into account (3.6) together with (3.5). Indeed, since \( f(ze^{-iu}) = \sum_{k=0}^{\infty} a_k z^k e^{-iku}, z \in D \), is absolutely convergent, we can write

\[ W_t^b f(z) = \sum_{k=0}^{\infty} a_k z^k \mathbb{E}[e^{-ikB(\xi_t)}] \]

\[
= \sum_{k=0}^{\infty} a_k z^k \int_{\mathbb{R}} e^{-iku} \ell_\delta(u, t) du
\]

\[ = \sum_{k=0}^{\infty} a_k z^k \int_{0}^{+\infty} \frac{1}{\sqrt{2 \pi y}} m_y(y, t) dy \int_{\mathbb{R}} e^{-iku} e^{-\frac{y^2}{2}} du
\]

\[ = \sum_{k=0}^{\infty} a_k z^k \int_{0}^{+\infty} e^{-\frac{y^2}{2}} m_y(y, t) dy
\]

\[ = \sum_{k=0}^{\infty} a_k z^k \mathbb{E}(e^{-\frac{\cdot^2}{2} \xi_t}) \]

By using the same arguments in [9], it is possible to prove that if \( z_n, z_0 \in \overline{D} \), with \( \lim_{n \to \infty} z_n = z_0 \), we get

\[ |W_t^b f(z_n) - W_t^b f(z_0)| \leq \int_{\mathbb{R}} \omega_1(f; |z_n - z_0|) \ell_\delta(u, t) du
\]

\[ = \omega_1(f; |z_n - z_0|), \]

where \( \omega_1(f; \delta) := \sup \{|f(u) - f(v)|; |u - v| \leq \delta, u, v \in \overline{D} \} \) is the modulus of continuity of \( f \).

Then if \( f \) is continuous on \( \overline{D} \), the integral \( W_t^b f(z) \) is continuous on \( \overline{D} \), as \( n \to \infty \).

From (3.10) and by exploiting (3.5), we obtain that

\[ R_b W_t^b f(z) = \sum_{k=0}^{\infty} a_k z^k \int_{0}^{+\infty} e^{-\frac{\cdot^2}{2} \xi_t} d\theta f(\theta) \]

\[ = \sum_{k=0}^{\infty} a_k z^k \frac{g(\theta)}{\frac{k^2}{2} + g(\theta)}. \]

(ii) From Theorem 2.1 in [6], we can observe that: 1) \( D_t^b W_t^b f(z) \) is well-defined since the integral appearing in the definition of \( D_t^b \) is absolutely convergent in the Banach space \( (A(D), || \cdot ||) \); 2) for \( b > 0, t \mapsto W_t^b f(\cdot) \) is globally Lipschitz in \( (A(D), || \cdot ||) \) and then \( \frac{\partial}{\partial t} W_t^b f(\cdot) \) exists in \( (A(D), || \cdot ||) \) for a.a. \( t \geq 0 \). In order to prove that (3.10) coincides with the solution of (3.12) with initial condition (3.13) we take the time-Laplace transform of both sides of (3.12). By applying the result (2.18) in [21], on the Laplace transform of the generalized derivative (3.2), we obtain
exploiting the theory of wrapped distribution, for any \( t > 0 \) we consider the definition
\[
B(t) = \int_0^t f(s) \, ds.
\]
Therefore, the probability distribution on a circle is characterized by its Fourier coefficients (see [7], Theorem XIX 6.1). In our case, for \( k \in \mathbb{N} \), we have that
\[
\phi_k := \int_0^{2\pi} e^{ik\varphi} \mu_{\mathcal{B}_g}(\varphi, t) \, d\varphi = \sum_{k=-\infty}^{\infty} \int_{2k\pi}^{2(k+1)\pi} e^{ik\varphi} \ell_g(\varphi, t) \, d\varphi
\]
\[
= \mathbb{E}[e^{ikB(\mathcal{E}_g(t))}] = \mathbb{E}[e^{\ell_g(\varphi, t)}] = d_k(t).
\]

Therefore,
\[
\mu_{\mathcal{B}_g}(\varphi) = \frac{1}{2\pi} \sum_{k=-\infty}^{\infty} \phi_k e^{-ik\varphi} = \frac{1}{2\pi} \left( 1 + 2 \sum_{k=1}^{\infty} d_k(t) \cos(k\varphi) \right).
\]

We now evaluate the Laplace transform of the first moments of \( \mathcal{B}_g(t) \) by applying the results on the joint moments of the inverse subordinators given in [24]. In particular, we recall that, for the Laplace transform of \( K_{t_1, \ldots, t_n}(s_1, \ldots, s_n) := \mathbb{E}(\mathcal{E}_g(t_1) > s_1, \ldots, \mathcal{E}_g(t_n) > s_n) \), the following formula holds
\[
\tilde{K}_{\theta_1, \ldots, \theta_n}(s_1, \ldots, s_n) := \int_0^\infty \cdots \int_0^\infty e^{-\theta_1 t_1 - \cdots - \theta_n t_n} K_{t_1, \ldots, t_n}(s_1, \ldots, s_n) \, dt_1 \cdots dt_n
\]
We start by evaluating, for any $\eta$ where $\theta > 0$, then, by taking the time-Laplace transform and considering (4.5), we have that, for $\theta > 0$, $t \geq 0$, $r \in \mathbb{N}$

\begin{equation}
\mathcal{L}\left\{ \mathbb{E}[g(t)]^r; \theta \right\} = \frac{2g(\theta)}{\theta(r + 2g(\theta))}, \quad \theta > 0, t \geq 0, r \in \mathbb{N}
\end{equation}

and

\begin{equation}
\mathcal{L}\left\{ \mathbb{E}[g(t_1)g(t_2)]; \theta_1, \theta_2 \right\} = \frac{4g(\theta_1)g(\theta_2)[g(\theta_1 + \theta_2) + 2] + 3[g(\theta_1) + g(\theta_2) - g(\theta_1 + \theta_2)]}{\theta_1\theta_2[2 + g(\theta_1 + \theta_2)(3 + 2g(\theta_1)(1 + 2g(\theta_2)))},
\end{equation}

for $0 \leq t_1 < t_2$ and $\theta_1, \theta_2 > 0$.

Proof. The $r$-th moment in (4.2) can be easily obtained by a conditioning argument and by considering (3.3):

\[ V(t) := \mathbb{E}\left[ e^{tB(\mathcal{E}_t)} \right]^r = \mathbb{E}\left[ e^{t\mathcal{E}_t} \mathcal{E}_t \right] \]

\[ = \mathbb{E}e^{-\mathcal{E}_t} = \int_0^{+\infty} e^{-\frac{\mathcal{E}_t}{t}} m_g(s, t)ds. \]

Then, by taking the time-Laplace transform and considering (4.5), we have that, for $\theta > 0$,

\[ \mathcal{V}(\theta) = \int_0^{+\infty} e^{-\theta t} V(t)dt = \int_0^{+\infty} e^{-\frac{\mathcal{E}_t}{t}} m_g(s, \theta)ds = \frac{g(\theta)}{\theta(r/2 + g(\theta))}, \]

where $\tilde{m}_g(s, \theta) := \int_0^{+\infty} e^{-\theta t} m_g(s, t)dt$. In order to prove formula (4.3), we write

\begin{equation}
V(t_1, t_2) := \mathbb{E}[g(t_1)g(t_2)] = \mathbb{E}\left[ e^{tB(\mathcal{E}_t)_{\mathcal{E}_t}} \mathcal{E}_t \right] = \mathbb{E}\left[ e^{tB(\mathcal{E}_t(t_1))} + tB(\mathcal{E}_t(t_2)) \mathcal{E}_t \right] \mathbb{E}\left[ e^{tB(\mathcal{E}_t(t_1)) + tB(\mathcal{E}_t(t_2))} \mathcal{E}_t \right] = \mathbb{E}\left[ e^{tB(\mathcal{E}_t(t_1)) + tB(\mathcal{E}_t(t_2)) + \min\{\mathcal{E}_t(t_1), \mathcal{E}_t(t_2)\}} \right].
\end{equation}

We start by evaluating, for any $\eta_1, \eta_2 > 0$

\[ V_{\eta_1, \eta_2}(t_1, t_2) = \mathbb{E}e^{-\eta_1\mathcal{E}_t(t_1) - \eta_2\mathcal{E}_t(t_2)} \]

\[ = \int_0^{+\infty} \int_0^{+\infty} e^{-\eta_1 s_1 - \eta_2 s_2} \frac{\partial^2}{\partial s_1 \partial s_2} K_{t_1, t_2}(s_1, s_2)ds_1ds_2 \]

[by repeatedly integrating by parts]

\[ = K_{t_1, t_2}(0, 0) - \eta_1 \int_0^{+\infty} e^{-\eta_1 s_1} K_{t_1, t_2}(s_1, 0)ds_1 - \eta_2 \int_0^{+\infty} e^{-\eta_2 s_2} K_{t_1, t_2}(0, s_2)ds_2 + \eta_1 \eta_2 \int_0^{+\infty} \int_0^{+\infty} e^{-\eta_1 s_1 - \eta_2 s_2} K_{t_1, t_2}(s_1, s_2)ds_1ds_2. \]
We now consider that \( K_{t_1,t_2}(0,0) = P( E_{\theta}(t_1) > 0, E_{\theta}(t_2) > 0) = 1 \) and that \( K_{t_1,t_2}(s_1,0) = P( E_{\theta}(t_1) > s_1) \), so that we can write
\[
\int_{0}^{+\infty} e^{-\eta s_1} K_{t_1,t_2}(s_1,0) ds_1 = \int_{0}^{+\infty} e^{-\eta s_1} P( E_{\theta}(t_1) > s_1) ds_1 = \frac{1}{\eta} [1 - \tilde{m}_g(\eta, t_1)],
\]
and analogously for \( K_{t_1,t_2}(0,s_2) \). Therefore, we get
\[
V_{\eta,s_2}(t_1,t_2) = \tilde{m}_g(\eta, t_1) + \tilde{m}_g(\eta, t_2) - 1
\]
\begin{equation}
\tag{4.5}
\end{equation}
In order to apply (4.1), we evaluate the Laplace transform of (4.5), with respect to the time variables:
\[
\tilde{V}_{\eta,s_2}(\theta_1, \theta_2) := \int_{0}^{+\infty} \int_{0}^{+\infty} e^{-\theta_1 t_1 - \theta_2 t_2} V_{\eta,s_2}(t_1,t_2) dt_1 dt_2 = \frac{1}{\theta_2} \tilde{m}_g(\eta, \theta_1) + \frac{1}{\theta_1} \tilde{m}_g(\eta, \theta_2) - \frac{1}{\theta_1 \theta_2} + \eta \eta_2 \int_{0}^{+\infty} \int_{0}^{+\infty} e^{-\eta_1 s_1 - \eta_2 s_2} K_{\theta_1,\theta_2}(s_1,s_2) ds_1 ds_2,
\]
where \( \tilde{m}_g(\eta, \theta) := \int_{0}^{+\infty} e^{-\eta s} \tilde{m}_g(s, \theta) ds \). On the other hand, we can rewrite the last integral in (4.6), by applying (4.1), as follows
\[
\frac{1}{\theta_1 \theta_2} \int_{0}^{+\infty} \int_{s_1}^{+\infty} e^{-\eta_1 s_1 - \eta_2 s_2} e^{-s_1 [g(\theta_1 + \theta_2) - g(\theta_2)] - s_2 g(\theta_2)} ds_1 ds_2
\]
\[
+ \frac{1}{\theta_1 \theta_2} \int_{0}^{+\infty} \int_{s_1}^{+\infty} e^{-s_1 - s_2 g(\theta_2)} ds_1 ds_2
\]
\[
= \frac{1}{\theta_1 \theta_2} \int_{0}^{+\infty} \int_{s_1}^{+\infty} e^{-[\eta_1 g(\theta_1 + \theta_2) - g(\theta_2)] s_1} ds_1 ds_2
\]
\[
+ \frac{1}{\theta_1 \theta_2} \int_{0}^{+\infty} \int_{s_2}^{+\infty} e^{-[\eta_2 g(\theta_1 + \theta_2) - g(\theta_1)] s_2} ds_2 ds_1
\]
\[
= \frac{1}{\theta_1 \theta_2} \left[ \int_{0}^{+\infty} \int_{s_1}^{+\infty} e^{-s_1 A_1 - s_2 B_1} ds_1 ds_2 + \int_{0}^{+\infty} \int_{s_2}^{+\infty} e^{-s_1 B_1 - s_2 A_1} ds_1 ds_2 \right]
\]
\[
= \frac{1}{\theta_1 \theta_2} \left[ \frac{1}{B_2(A_1 + B_2)} + \frac{1}{B_1(A_1 + B_2)} \right],
\]
where we put \( A_1 := \eta_1 + g(\theta_1 + \theta_2) - g(\theta_2) \), for \( i, j = 1,2 \) and \( i \neq j \), \( B_i := \eta_1 + g(\theta_i) \), for \( i = 1,2 \). We consider that \( A_1 + B_2 = A_2 + B_1 = \eta_1 + \eta_2 + g(\theta_1 + \theta_2) \), so that we can write (4.6), by recalling (4.5), as
\begin{equation}
\tag{4.7}
\end{equation}
By taking into account that \( H_{\theta} \) is a.s. increasing and its inverse \( E_{\theta} \) is a.s. non-decreasing, so that \( \min(E_{\theta}(t_1), E_{\theta}(t_2)) = E_{\theta}(t_1) \) a.s., for \( t_2 > t_1 \), formula (4.3) follows from (4.7), with \( \eta_1 = 3/2 \) and \( \eta_2 = 1/2 \), after some algebraic calculations. \( \square \)
We are also able to give an integral representation for the mixed moment $E[\mathcal{B}_g(t)\mathcal{B}_g(s)]$, for $t, s \geq 0$.

**Theorem 4.2.** Let $U_g(\tau) := E[\mathcal{E}_g(\tau)]$, $\tau \geq 0$ and $E[(\mathcal{E}_g(t))^k] < \infty$, $k \in \mathbb{N}$, then

\[
E[\mathcal{B}_g(t)\mathcal{B}_g(s)] = E\mathcal{B}_g(t \lor s) + \frac{1}{2} \int_0^{t \wedge s} E\mathcal{B}_g(t \lor s - \tau)dU_g(\tau)
\]

for $t, s \geq 0$ and $t \neq s$, while $E[\mathcal{B}_g(t)\mathcal{B}_g(t)] = 1$.

**Proof.** Let $t > s$ and denoting $U_g(s, t; k, j) := E[(\mathcal{E}_g(s))^k(\mathcal{E}_g(t))^j]$, $s, t \geq 0$, $k, j \in \mathbb{N}$, we can write down

\[
E[\mathcal{B}_g(t)\mathcal{B}_g(s)] = E[e^{i(B(t) - B(s))}]
\]

\[
= E[e^{i(B(t) - B(s))}E[\mathcal{E}_g(t), \mathcal{E}_g(s)]]
\]

\[
= E[e^{-\frac{i}{2}(\mathcal{E}_g(t) - \mathcal{E}_g(s))^2}]
\]

\[
= \sum_{k=0}^{\infty} \frac{1}{k!} \left(-\frac{1}{2}\right)^k E[(\mathcal{E}_g(t) - \mathcal{E}_g(s))^k]
\]

\[
= \sum_{k=0}^{\infty} \frac{1}{k!} \left(-\frac{1}{2}\right)^k \sum_{j=0}^{k} (-1)^{k-j} \binom{k}{j} E[(\mathcal{E}_g(t))^j(\mathcal{E}_g(s))^{k-j}]
\]

\[
= \sum_{k=1}^{\infty} \frac{1}{k!} \left(-\frac{1}{2}\right)^k \sum_{j=0}^{k-1} (-1)^{k-j} \binom{k-1}{j} U_g(s, t; k - j, j)
\]

\[
+ \sum_{k=0}^{\infty} \frac{1}{k!} \left(-\frac{1}{2}\right)^k E[(\mathcal{E}_g(t))^k]
\]

\[
= \sum_{k=1}^{\infty} \frac{1}{k!} \left(-\frac{1}{2}\right)^{k-1} \sum_{j=0}^{k-1} (-1)^{k-j} \binom{k-1}{j} U_g(s, t; k - j, j)
\]

where we have singled out the term $j = k$ in the second summation, since it must be treated separately (in view of its different behavior for $s = 0$). Now we use the recursive representation of the moments given by Theorem 4.2, [24], so that (4.9) can be rewritten as follows

\[
E[\mathcal{B}_g(t)\mathcal{B}_g(s)] = \sum_{k=1}^{\infty} \frac{1}{k!} \left(-\frac{1}{2}\right)^{k-1} \sum_{j=0}^{k-1} (-1)^{k-j} \binom{k-1}{j}
\]

\[
\times \int_0^s (k - j)U_g(s - \tau, t - \tau; k - j - 1, j)dU_g(\tau)
\]

\[
+ \sum_{k=1}^{\infty} \frac{1}{k!} \left(-\frac{1}{2}\right)^{k-1} \sum_{j=0}^{k-1} (-1)^{k-j} \binom{k-1}{j}
\]

\[
\times \int_0^t jU_g(s - \tau, t - \tau; k - j, j - 1)dU_g(\tau) + E\mathcal{B}_g(t)
\]

\[
= I_1 + I_2 + E\mathcal{B}_g(t).
\]

The first term in (4.10) can be treated as follows

\[
I_1 = \sum_{k=1}^{\infty} \frac{1}{k!} \left(-\frac{1}{2}\right)^{k-1} \sum_{j=0}^{k-1} (-1)^{k-j} \binom{k-1}{j}
\]
Let $D$ be a transformed continuous-time random walk on a circle. Let us denote by
\[X(t) = \frac{1}{a} \frac{1}{2} \sum_{j=0}^{k-1} (-1)^{k-j} \binom{k-1}{j} (t - j) \int_0^t E [J(t-\tau)]^{k-j} J(t-\tau) d\tau \]
while the second one reads
\[Y(t) = \frac{1}{a} \frac{1}{2} \sum_{j=0}^{k-1} (-1)^{k-j} \binom{k-1}{j} (t - j) \int_0^t E [J(t-\tau)]^{k-j} J(t-\tau) d\tau \]

We now prove that the wrapped Brownian motion $B\|_g$ is a solution to the fractional heat equation
\[\frac{1}{2} \int_0^t \mathbb{E} [B(t-\tau)B(s-\tau)] d\tau \]

The result follows by inserting $I_1$ and $I_2$ into (4.10) and treating the case $s > t$ analogously. \qed

We now prove that the wrapped Brownian motion $B\|_g$ can be obtained as a scaling limit of a transformed continuous-time random walk on a circle. Let us denote by $\approx$ the convergence in the $J_1$ topology and by $\Rightarrow$ the convergence in the $M_1$ topology in the Skorohod space $D([0,T],\mathbb{R}^d)$, for $T > 0$ and $d = 1,2,...$ (see [25] and [19] for details on $J_1$ and $M_1$ topologies).

**Theorem 4.3.** Let $c > 0$ and let $Y_j^{(c)}$, $j = 1,2,...$, be i.i.d. random variables with finite moments and scale parameter $c$. Let moreover $J_j^{(c)}$, $j = 1,2,...$, be i.i.d. random variables, independent of $Y_j^{(c)}$, for any $j = 1,2...$ and for any $c > 0$, and such that for $T^{(c)}(ct) := \sum_{j=1}^{(c)} J_j^{(c)}$ the following

\[\times \int_0^s (k-j)U_g(s-\tau,t-\tau;k-j+1,1)dU_g(\tau) \]

\[= \sum_{k=1}^{\infty} \frac{1}{k!} \left( -\frac{1}{2} \right)^k \sum_{j=0}^{k-1} (-1)^{k-j} \binom{k-1}{j} \int_0^s E [(J(t-\tau))^{k-j} J(t-\tau)] dU_g(\tau) \]

\[= \sum_{k=2}^{\infty} \frac{1}{(k-1)!} \left( -\frac{1}{2} \right)^{k-1} \sum_{m=0}^{k-2} (-1)^{k-m-1} \binom{k-1}{m} \int_0^s E [(J(t-\tau))^{k-m} J(t-\tau)] dU_g(\tau) \]

\[= -\frac{1}{2} \sum_{k=2}^{\infty} \frac{1}{(k-1)!} \left( -\frac{1}{2} \right)^{k-1} \int_0^s E [(J(t-\tau) - J(s-\tau))^{k-1}] dU_g(\tau) \]

\[+ \frac{1}{2} \sum_{k=2}^{\infty} \frac{1}{(k-1)!} \left( -\frac{1}{2} \right)^{k-1} \int_0^s E [(J(t-\tau))^{k-1}] dU_g(\tau) \]

\[= -\frac{1}{2} \int_0^s \mathbb{E} [B_g(t-\tau)B_g(s-\tau)] dU_g(\tau) + \frac{1}{2} \int_0^s \mathbb{E} B_g(t-\tau) dU_g(\tau). \]
convergence holds \( \{T^{(c)}(ct)\}_{t \geq 0} \overset{J_1}{\to} \{\mathcal{H}_g(t)\}_{t \geq 0} \), as \( c \to +\infty \), in \( D([0, +\infty), \mathbb{R}^+) \). Then

\[
\{e^{\sum_{j=1}^{n(c)} Y_j^{(c)}}\}_{t \geq 0} \overset{M}{\to} \{\mathfrak{B}_g(t)\}_{t \geq 0}, \quad c \to +\infty,
\]
in \( D([0, +\infty), S_1) \), where \( N^{(c)}_i := \max\{n \geq 0 : T^{(c)}(n) \leq t\} \).

**Proof.** The convergence in (4.11) follows by the application of Theorem 2.1 and Corollary 2.4 in [18], in the special case where \( A(t) = B(t), t \geq 0 \): indeed, let \( \text{Disc}(x) \) be the set of discontinuities of \( x \), the assumption that \( \text{Disc}(\{A(t)\}_{t \geq 0}) \cap \text{Disc}(\{\mathcal{H}_g(t)\}_{t \geq 0}) = \emptyset \) a.s. is automatically satisfied because, as well-known, it is always possible to choose a version of Brownian motion such that its trajectories are continuous with probability one. Moreover, the Lévy measure of \( \mathcal{H}_g \) is infinite on \([0, +\infty)\) by assumption. By the independence of \( J_j^{(c)} \) and \( Y_j^{(c)} \), for any \( j = 1, 2, \ldots \) and by the functional central limit theorem, we have that

\[
\sum_{j=1}^{n(c)} Y_j^{(c)}, T^{(c)}(ct)_{i \geq 0} \overset{J_1}{\to} \{B(t), \mathcal{H}_g(t)\}_{t \geq 0}, \quad c \to +\infty,
\]
in the \( J_1 \) topology on \( D([0, +\infty), \mathbb{R} \times \mathbb{R}^+) \). Therefore, by the above mentioned Theorem 2.1 in [18], the following convergence holds

\[
\sum_{j=1}^{n(c)} Y_j^{(c)}_{i \geq 0} \overset{M}{\to} \{B(\mathcal{E}_g(t))\}_{t \geq 0}, \quad c \to +\infty,
\]
in the \( M_1 \) topology on \( D([0, +\infty), \mathbb{R}) \). The result finally follows by applying the continuous mapping theorem to the function \( \phi(\cdot) : \mathbb{R} \to \mathbb{C} \) defined as \( \phi(x) = e^{ix}, x \in \mathbb{R} \). \( \square \)

We refer to [18] for the description of some relevant situations where this kind of convergence can be appropriately applied.

4.0.1. **The stable case.** For \( g(\theta) = \theta^{\alpha}, \alpha \in (0, 1) \), formula (3.1) holds for \( a = 0 \) and \( b = \lim_{\theta \to +\infty} g(\theta)/\theta = 0 \). Moreover, the process \( \mathcal{E}_g(t) \) reduces to the inverse of the \( \alpha \)-stable subordinator (see e.g. [20]) and the operator \( \mathcal{D}_\beta^g \) coincides with the Caputo time-fractional derivative of order \( \alpha \), namely \( \partial^\alpha/\partial t^\alpha \). In this case, if we denote \( W_t^\alpha \) as \( W_t^\alpha \), we have that

\[
W_t^\alpha(f)(z) = \frac{1}{\Gamma(\alpha/2)} \int_{\mathbb{R}} f(ze^{iu}) W_{-z/2, 1-z} \left( -\frac{|u|}{\Gamma(\alpha/2)} \right) du,
\]

where

\[
W_{\beta, \gamma}(x) = \sum_{k=0}^{\infty} \frac{x^k}{k! \Gamma(\beta k + \gamma)},
\]
is the Wright function, defined for \( \beta, \gamma, x \in \mathbb{C} \). The representation (4.12) follows by the fact that the fundamental solution of the time-fractional diffusion equation

\[
\frac{\partial^\alpha}{\partial t^\alpha} u(x,t) = \frac{1}{2} \frac{\partial^2}{\partial x^2} u(x,t),
\]

involving Caputo time-fractional derivatives of order \( \alpha \in (0, 1) \) is given by

\[
u(x,t) = \frac{1}{\Gamma(\alpha/2)} W_{-\alpha/2, 1-\alpha/2} \left( -\frac{|x|}{\Gamma(\alpha/2)} \right),
\]

see for example [15].

Then, in this case, as a consequence of Theorem 3.1, we have the following result.
Corollary 4.1. Let $E_\alpha(x) := \sum_{j=0}^{\infty} \frac{x^j}{\Gamma(j+1)}$, for $x, \alpha \in \mathbb{C}$, if $f(x) \in A(D)$, then we have on $D$ that

$$W_t^\alpha f(z) = \mathbb{E} f(z e^{iB_t(E_\alpha(t))}) = \int_{\mathbb{R}} f(z e^{iu}) \ell_\alpha(u,t) du = \sum_{k=0}^{\infty} a_k d_k(t) z^k,$$

where $d_k(t) = E_\alpha \left( -\frac{k^\alpha}{2} \right)$, $\alpha \in (0,1)$, $E_\alpha(t)$ is the inverse of the $\alpha$-stable subordinator and $\ell_\alpha$ is the probability density of the time-changed Brownian motion $B_\alpha(t) := B(E_\alpha(t))$.

Moreover, $W_t^\alpha f(z)$ is the unique solution $u(z,t)$ for the fractional Cauchy problem

\begin{equation}
\begin{aligned}
\frac{\partial^\alpha u}{\partial t^\alpha} (z,t) &= \frac{1}{2} \frac{\partial^2 u}{\partial z^2} (z,t), \\
(z,t) &\in \mathbb{R}^+ \times D, \quad z = re^{i\varphi}, \quad r \in (0,1), \quad \varphi \in [0,2\pi)
\end{aligned}
\end{equation}

\begin{equation}
u(0,z) = f(z), \quad z \in D, \ f \in A(D).
\end{equation}

Remark 4.1. Observing that, for $\alpha = 1/2$ the following equality in distribution holds

\begin{equation}
B(E_{1/2}(t)) \overset{d}{=} B_1(\{B_2(t)\}),
\end{equation}

where $B_1$ and $B_2$ are independent, we have that

\begin{equation}
W_t^{1/2} f(z) = \mathbb{E} f(z e^{iB_{1/2}(t)})
\end{equation}

coincides with the solution to (4.16), for $\alpha = 1/2$. Therefore, in this special case, we have an iterated Brownian motion on the circle.

Remark 4.2. In the stable case, i.e. for $g(\theta) = \theta^\alpha$, the inverse transform of the $r$-th moment given in (4.2) can be easily obtained and reads

$$\mathbb{E} [B_\alpha(t)]^r = E_\alpha \left( -\frac{r^\alpha}{2} \right), \quad r \in \mathbb{N}.$$

Moreover, we can evaluate explicitly the mixed moment in (4.9), by recalling that $U_\alpha(\tau) = \mathbb{E} E_\alpha(\tau) = \frac{\tau^\alpha}{\Gamma(\alpha+1)}$ and that $\mathbb{E} B_\alpha(\tau) = E_\alpha(-\tau^\alpha/2)$, so that, for $s < t$, we get

\begin{align*}
\mathbb{E}[B_\alpha(t)B_\alpha(s)] &= E_\alpha \left( -\frac{\alpha^\alpha}{2} \right) + \frac{\alpha}{2\Gamma(\alpha+1)} \int_0^s E_\alpha \left( -\frac{(t-\tau)^\alpha}{2} \right) \tau^{\alpha-1} d\tau \\
&= E_\alpha \left( -\frac{\alpha^\alpha}{2} \right) + \frac{\alpha}{2\Gamma(\alpha)} \int_0^{s/t} E_\alpha \left( -\frac{\alpha(1-y)^\alpha}{2} \right) y^{\alpha-1} dy \\
&= E_\alpha \left( -\frac{\alpha^\alpha}{2} \right) + \frac{\alpha}{2\Gamma(\alpha)} \sum_{j=0}^{\infty} \left( -\frac{\alpha^\alpha}{2} \right)^j \frac{1}{\Gamma(\alpha j + 1)} B(\alpha j + 1, \alpha; s/t),
\end{align*}

where $B(a,b;x) := \int_0^x z^{a-1}(1-z)^{b-1}dz$ is the incomplete beta function. Since, for $s \to t$, the previous expression reduces to one, we can write, for any $s, t \geq 0$,

\begin{align*}
\mathbb{E}[B_\alpha(t)B_\alpha(s)] &= E_\alpha \left( -\frac{(s \vee s)^\alpha}{2} \right) \\
&+ \frac{(s \vee s)^\alpha}{\Gamma(\alpha)} \sum_{j=0}^{\infty} \frac{(-t \vee s)^\alpha/2)^j}{\Gamma(\alpha j + 1)} B(\alpha j + 1, \alpha; (t \wedge s)/(t \vee s)).
\end{align*}

Finally, it is easy to check that, for $\alpha = 1$, (4.8) reduces to $e^{-(t \vee s - t \wedge s)/2}$ as it should be, since, in this case $E_\alpha(t) = t$, a.s. for any $t \geq 0$. 

4.0.2. The tempered stable case. For \( g(\theta) = (\theta + \mu)^\alpha - \mu^\alpha \), for \( \theta, \mu \geq 0 \), \( a = b = 0 \), and the process \( \mathcal{E}_t \) reduces to the inverse of the tempered stable subordinator (in the next \( \mathcal{E}_T \)) and the operator \( D_t^\alpha \) coincides with the tempered derivative (see e.g. \[2\] and \[3\]) denoted by

\[
D_t^\alpha f(t) := e^{-\mu t} \frac{\partial}{\partial \alpha}(e^{\mu t} f(t)) - \mu^\alpha f(t) = \left( \mu + \frac{d}{dt} \right)^\alpha f(t).
\]

Since in this case the tail Lévy measure is given by

\[
w(s) = \frac{\alpha \mu^\alpha}{\Gamma(1 - \alpha)} \Gamma(-\alpha, \mu s) \Gamma(1),
\]

where \( \Gamma(\rho, x) = \int_x^{+\infty} e^{-\omega} \omega^{\rho-1} d\omega \), is the upper incomplete gamma function. The tempered derivative (4.19) can be also expressed in a convolution form, as follows

\[
D_t^\alpha f(t) = \frac{\alpha \mu^\alpha}{\Gamma(1 - \alpha)} \int_0^t \frac{\partial}{\partial z} f(t - z) \Gamma(-\alpha, \mu z) dz.
\]

**Corollary 4.2.** Let \( W_t^\alpha \) be denoted as \( W_t^{\alpha,\mu} \), for \( g(\theta) = (\theta + \mu)^\alpha - \mu^\alpha \), then the complex integral

\[
W_t^\alpha f(z) = \int_{\mathbb{R}} f(z e^{iu}) \ell_{\alpha,\mu}(u, t) du = \sum_{k=0}^{\infty} a_k z^k d_k(t),
\]

where \( \ell_{\alpha,\mu} \) is the probability density of the time-changed Brownian motion \( B(\mathcal{E}_T(t)) \) and

\[
d_k(t) = \frac{1}{\Gamma(\alpha)} \int_0^t \frac{\partial^2 u}{\partial \varphi^2} (z, t) dz
\]

is the unique solution of the fractional Cauchy problem

\[
D_t^\alpha u(z, t) = \frac{\partial^2 u}{\partial \varphi^2} (z, t),
\]

\((z, t) \in D \times \mathbb{R}^+, \quad z = re^{i\varphi}, \quad r \in (0, 1), \quad \varphi \in [0, 2\pi)\)

\[(4.25) \quad u(z, 0) = f(z), \quad z \in \partial D, f \in A(D).\]

**Proof.** The result follows by using Theorem 3.1 and by inverting the Laplace transform

\[
\hat{d}_k(\theta) = (\theta + \mu)^\alpha - \mu^\alpha \theta\left[(\theta + \mu)^\alpha - \mu^\alpha + \frac{\theta^2}{2}\right].
\]

This can be done by applying the well-known formula of the Laplace transform of the two-parameter Mittag-Leffler function (see e.g. \[11\]) and recalling that (see \[4\])

\[
\mathcal{L}\{\Gamma(\alpha; \mu x); \theta\} = \frac{(\mu + \theta)^\alpha - \mu^\alpha}{\theta(\mu + \theta)^\alpha}.
\]

**Remark 4.3.** Note that, in the special case \( \mu = 0 \), the expression of \( d_k(t) \) reduces, for any \( k \in \mathbb{N} \) and \( t \geq 0 \) to

\[
d_k(t) = \int_0^t \frac{1}{z} E_{\alpha,\mu}( - \frac{k^2}{2} z^\alpha ) dz = E_{\alpha}( - \frac{k^2}{2} t^\alpha ),
\]

which coincides with the stable case.
5. Higher dimensional extensions

Following [8]-[9], we can also consider the n-dimensional fractional Cauchy problem extending (3.12)-(3.13). In this case, the probabilistic interpretation of the solution for the complexified multidimensional fractional heat equation can be obtained by means of n-dimensional Brownian motions time changed with the inverse of the subordinator $E_g$.

Let $z_1, z_2, \ldots, z_n \in \mathbb{D}$ and $f(z_1, z_2, \ldots, z_n) \in A(D^n)$, which means that $f(z_1, z_2, \ldots, z_n)$ belongs to $A(D)$ for each complex variable $z_1, z_2, \ldots, z_n$. Let us deal with the arguments developed in Section 3 and extend them to the multidimensional case. Let us introduce the following complex motions time changed with the inverse of the subordinator $E_g$.

Theorem 5.1.

Then, we have the following result representing the multidimensional version of Theorem 3.1.

\begin{equation}
(5.1)
\tilde{W}_t^g f(z_1, z_2, \ldots, z_n) = \frac{1}{(2\pi)^{n/2}} \int_{-\infty}^{\infty} \prod_{i=1}^{n} f(z_1 e^{-iu_i}, \ldots, z_n e^{-iu_n}) du_1 \cdots du_n
\end{equation}

\begin{equation}
\times \int_{0}^{\infty} e^{-\frac{t^2 + \sum_{i=1}^{n} \frac{i^2}{y^2}}{g_1(y, t)}} m_g(y, t) dy
\end{equation}

\begin{equation}
= \mathbb{E} f \left( z_1 e^{-iB_1(E_g(t))}, \ldots, z_n e^{-iB_n(E_g(t))} \right)
\end{equation}

\begin{equation}
= \mathbb{E} \left( \mathcal{B}_{1,g}(t), \mathcal{B}_{2,g}(t), \ldots, \mathcal{B}_{n,g}(t) \right),
\end{equation}

for $z_1, z_2, \ldots, z_n \in \mathbb{D}$. Furthermore, let $\mathcal{B}_{g}^{z_1, \ldots, z_n} := \{z_k e^{-iB_k(E_g(t))}\}_{t \geq 0}$ with $z_k = r_k e^{i\varphi_k}$, $r_k \in (0, 1]$, $\varphi_k \in [0, 2\pi)$, and $\{B_k(t)\}_{t \geq 0}$ independent standard Brownian motions, for $k = 1, 2, \ldots, n$. Therefore, the time-changed process

\begin{equation}
\mathcal{B}_{g}^{z_1, \ldots, z_n} := \left\{ \left( \mathcal{B}_{1,g}^{z_1}(t), \mathcal{B}_{2,g}^{z_2}(t), \ldots, \mathcal{B}_{n,g}^{z_n}(t) \right) \right\}_{t \geq 0}
\end{equation}

represents a n-dimensional wrapped Brownian motion on the n-dimensional circle $S^n := S_{r_1} \times \cdots \times S_{r_n}$, where the coordinate processes are the circular Brownian motions (3.9) with random time $E_g$ (and then they are not independent). Therefore, simple calculations show that $\mathcal{B}_{g}^{z_1, \ldots, z_n}$ has covariance matrix with entries

\begin{equation}
q_{i,j} = \mathbb{E} \left[ \mathcal{B}_{i,g}^{z_i}(t) \mathcal{B}_{j,g}^{z_j}(t) \right] - \mathbb{E} \left[ \mathcal{B}_{i,g}^{z_i}(t) \right] \mathbb{E} \left[ \mathcal{B}_{j,g}^{z_j}(t) \right]
\end{equation}

\begin{equation}
= \begin{cases} z_i z_j \left( \mathbb{E} e^{-\varepsilon_{x_i}(t)} - (\mathbb{E} \varepsilon_{x_i}(t))^2 \right), & i \neq j, \\ z_i^2 \left( 1 - (\mathbb{E} \varepsilon_{x_i}(t))^2 \right), & i = j. \end{cases}
\end{equation}

Now, we recall that, by the multivariate Taylor’s expansion, we can write

\begin{equation}
f(z_1, \ldots, z_n) = \sum_{k_1, \ldots, k_n=0}^{\infty} a_{k_1, \ldots, k_n} z_1^{k_1} \cdots z_n^{k_n}.
\end{equation}

Then, we have the following result representing the multidimensional version of Theorem 3.1.

Theorem 5.1. (i) If $f \in A(D^n)$, then we have that the complex integral (5.1) can be written as

\begin{equation}
(5.2)
\tilde{W}_t^g f(z_1, z_2, \ldots, z_n) = \sum_{k_1, \ldots, k_n=0}^{\infty} a_{k_1, \ldots, k_n} z_1^{k_1} \cdots z_n^{k_n} d_{k_1, \ldots, k_n}(t),
\end{equation}

where $d_{k_1, \ldots, k_n}(t) = \mathbb{E} \left[ e^{-\frac{t^2}{g_1(t)} \sum_{i=1}^{n} k_i^2} \right]$. Furthermore

\begin{equation}
(5.3)
R_t^g \tilde{W}_t^g f(z_1, z_2, \ldots, z_n) := \int_{0}^{\infty} e^{-\theta t} \tilde{W}_t^g f(z_1, z_2, \ldots, z_n) dt
\end{equation}

for $z_1, z_2, \ldots, z_n \in \mathbb{D}$.
\[
\tilde{d}_{k_1,\ldots,k_n}(\theta) = \frac{g(\theta)/\theta}{g(\theta) + (k_1^2 + \ldots + k_n^2)/2},
\]

where

\[(5.4)\]

(ii) Let \( t > 0, f \in A(D^n) \) and \( z_1, \ldots, z_n \in \mathcal{D} \). The integral operator \((5.1)\) is the unique solution

\[u(z_1, z_2, \ldots, z_n, t) = \mathcal{W}_t^\psi f(z_1, z_2, \ldots, z_n)\]

(\( \text{that belongs to } A(D) \) for each complex variable \( z_k \)) of the fractional Cauchy problem

\[(5.5)\]

\[D_t^\theta u(z_1, z_2, \ldots, z_n, t) = \frac{1}{2} \left[ \frac{\partial^2}{\partial \varphi_1^2} + \ldots + \frac{\partial^2}{\partial \varphi_n^2} \right] u(z_1, z_2, \ldots, z_n, t),\]

\[z_1 = r_1 e^{i\varphi_1}, \ldots, z_n = r_n e^{i\varphi_n} \in D \setminus \{0\},\]

\[(5.6)\]

\[u(z_1, z_2, \ldots, z_n, 0) = f(z_1, z_2, \ldots, z_n),\]

where \( \varphi_k \) is the principal value of \( z_k \).

\textbf{Proof.} (i) The representation \((5.2)\) follows by writing \((5.1)\) as follows

\[\mathcal{W}_t^\psi f(z_1, z_2, \ldots, z_n) = \sum_{k_1,\ldots,k_n=0}^{\infty} a_{k_1,\ldots,k_n} \int_{-\infty}^{+\infty} du_{n} \cdots \int_{-\infty}^{+\infty} du_{1} e^{-i\sum_{j=1}^{n} u_{j} k_{j}}\]

\[\times \int_{0}^{+\infty} e^{-\frac{u_{1}^2 + \ldots + u_{n}^2}{2}} \mathcal{W}_t^\psi f(z_1, z_2, \ldots, z_n) dy\]

\[= \sum_{k_1,\ldots,k_n=0}^{\infty} a_{k_1,\ldots,k_n} \mathcal{E} \left[ e^{-i\sum_{j=1}^{n} k_{j} B_{j}(\xi(t))} \right]\]

\[= \sum_{k_1,\ldots,k_n=0}^{\infty} a_{k_1,\ldots,k_n} \mathcal{E} \left[ e^{-\frac{\xi(t)}{\sum_{j=1}^{n} k_{j}}} \right].\]

Since the time-Laplace transform of \( \mathcal{E} e^{-i\sum_{j=1}^{n} k_{j} B_{j}(\xi(t))} \) coincides with \((5.4)\) (see, for example, [5]), the result \((5.3)\) holds true.

(ii) Analogously to the one-dimensional case, we take the time-Laplace transform of both sides of \((5.5)\), as follows

\[\mathcal{L}(D_t^\theta \mathcal{W}_t^\psi f)(z_1, \ldots, z_n; \theta)\]

\[(5.7)\]

\[= \frac{g(\theta)}{\theta} \left[ \sum_{k_1,\ldots,k_n=0}^{\infty} a_{k_1,\ldots,k_n} \frac{z_1^{k_1} \ldots z_n^{k_n} g(\theta)}{g(\theta) + (k_1^2 + \ldots + k_n^2)/2} - f(z_1, \ldots, z_n) \right]\]

and

\[\frac{1}{2} \left[ \frac{\partial^2}{\partial \varphi_1^2} + \ldots + \frac{\partial^2}{\partial \varphi_n^2} \right] \mathcal{L}(\mathcal{W}_t^\psi f)(z_1, \ldots, z_n; \theta)\]

\[(5.8)\]

\[= -\frac{1}{2} \sum_{k_1=0,\ldots,k_n=0}^{\infty} \frac{g(\theta)/\theta}{g(\theta) + (k_1^2 + \ldots + k_n^2)/2} a_{k_1,\ldots,k_n} (k_1^2 + \ldots + k_n^2) z_1^{k_1} \ldots z_n^{k_n}.\]

Therefore \((5.7)\), \((5.8)\) and \((5.2)\) allow to conclude the proof. \(\square\)
