APPLICATIONS OF FOLIATION THEORY TO INVARIANT THEORY

RICARDO A. E. MENDES AND MARCO RADESCHI

Abstract. We give applications of Foliation Theory to the Classical Invariant Theory of real orthogonal representations, including: The solution of the Inverse Invariant Theory problem for finite groups. An if-and-only-if criterion for when a separating set is a generating set. And the introduction of a class of generalized polarizations which, in the case of representations of finite groups, always generates the algebra of invariants of their diagonal representations.

1. Introduction

Invariant Theory without groups. Given a representation \( V \) of a group \( G \), Invariant Theory studies the algebra of polynomials \( f \) on \( V \) which are invariant under the \( G \)-action \((g.f)(x) = f(g^{-1}x)\).

We will restrict ourselves to the case where \( V \) is a real, finite-dimensional inner product space (a Euclidean vector space, for short), and \( G \) is a compact group acting by orthogonal transformations. In this case, the algebra \( \mathbb{R}[V]^G \) of invariant polynomials can be thought of as the algebra of polynomial functions \( V \to \mathbb{R} \) which are constant along the fibers of the quotient map \( \pi : V \to V/G \). Moreover, \( \mathbb{R}[V]^G \) separates orbits, in particular the orbit space \( V/G \) is Hausdorff.

This picture can be generalized to a setup not involving any group at all: notice, in fact, that the fibers of \( \pi : V \to V/G \) (i.e. the \( G \)-orbits) are smooth, embedded and pair-wise equidistant submanifolds of \( V \). Using these properties as a definition, one arrives at the notion of infinitesimal manifold submetry \( \sigma : V \to X \), from \( V \) onto a metric space \( X \), see Section 3 for a precise definition. Given such a map, one can still define the algebra \( B(\sigma) \) of polynomials constant along the fibers of \( \sigma \), called basic polynomials.

The interaction between infinitesimal manifold submetries \( \sigma : V \to X \) and their algebra \( B(\sigma) \) was studied in [MR20b]. In the present paper, we show how this more general context is natural is that it allows for the solution of problems that seem to have been out of

reach of classical Invariant Theory. Take, for example, the Inverse Invariant Theory Problem, about characterizing the sub-algebras of $\mathbb{R}[V]$ which are algebras of invariants of some representation. This seems to only have been solved over finite fields [NS02, Section 8.4], but in our more general context there is a satisfying solution. In fact, define Laplacian algebras, as the sub-algebras $A \subset \mathbb{R}[V]$ that contain the “distance-squared” polynomial $r^2 = \sum_i x_i^2$ and are preserved by the differential operator “dual” to $r^2$, namely the Laplacian $\Delta = \sum_i \partial^2/\partial x_i^2$. We then prove:

**Theorem A.** Let $V$ be a Euclidean vector space. Then, taking algebras of basic polynomials gives a one-to-one correspondence between infinitesimal manifold submetries from $V$, and Laplacian sub-algebras of $\mathbb{R}[V]$.

Using the results in [MR20b], this provides a solution to the Inverse Invariant Theory Problem for finite groups:

**Theorem B (Corollary [10]).** A subalgebra $A \subset \mathbb{R}[V]$ is the algebra of invariants for some orthogonal representation by a finite group if and only if $A$ is a Laplacian algebra whose field of fractions has transcendence degree equal to $\dim(V)$.

**Application to separating sets.** Another application to Classical Invariant Theory concerns separating sets, which is a topic of much recent research — see [DK15, Section 2.4] and references therein. In our context, a set $S$ of $G$-invariant polynomials is called separating if it separates $G$-orbits. The following characterizes the separating sets which generate the whole algebra of invariants:

**Theorem C.** Let $V$ be a real orthogonal representation of the compact group $G$, and let $\mathbb{R}[V]^G$ denote its algebra of invariants. Let $S \subset \mathbb{R}[V]^G$ be a separating set containing $r^2$, and $B$ the subalgebra generated by $S$. Then $B = \mathbb{R}[V]^G$ if and only if $\Delta f$ and $\langle \nabla f, \nabla g \rangle$ belong to $B$, for every $f, g \in S$.

We note that the condition on $S$ given in Theorem C is equivalent to $B$ being Laplacian. For a different criterion for a separating set to be generating, in the context of rational representations of reductive groups over algebraically closed fields, see [DK15, Theorem 2.4.6].

Theorem C can be a useful tool to prove First Fundamental Theorems, that is, to show that certain sets of polynomials generate the algebra of basic polynomials of a given manifold submetry, see Subsection 4.1 for a few illustrative examples.

**Application to polarizations.** Taking the sum of $k$ copies of a $G$-representation $V$ produces a $G$-representation $V^k$. Recall that, given a homogeneous $G$-invariant polynomial $f$ of degree $d$, its polarizations (which we will sometimes call classical polarizations to distinguish them from a generalization described below) are the multi-variable invariants $f_\alpha \in \mathbb{R}[V^k]^G$, where $\alpha = (\alpha_1, \ldots, \alpha_k)$ runs through the multi-indices with $|\alpha| = \sum_i \alpha_i = d$, defined by

\[
(1) \quad f \left( \sum_i s_i v_i \right) = \sum_{|\alpha|=d} s_1^{\alpha_1} \cdots s_k^{\alpha_k} f_\alpha(v_1, \ldots, v_k)
\]

where $s_i$ are formal variables.

Alternatively, the algebra generated by all polarizations can also be seen as the smallest sub-algebra of $\mathbb{R}[V^k]$ containing $\mathbb{R}[V]^G$ (seen as polynomials depending only on the first variable $v_1$) and closed under a certain family of differential operators called polarization operators, see Subsection 5.1.
Inspired by the latter form of the definition, we introduce a sub-algebra $A^{(k)} \subset \mathbb{R}[V^k]$, which we call the algebra of \textit{generalized polarizations}, associated to any Laplacian algebra $A \subset \mathbb{R}[V]$. It is defined as the smallest Laplacian algebra containing $A$ (seen as polynomials depending only on the first variable $v_1$) and the inner products $(v_1, \ldots, v_k) \mapsto \langle v_i, v_j \rangle$ for all $i, j$. When $A = \mathbb{R}[V]$ for a compact $G$, the algebra $A^{(k)}$ contains all classical polarizations, and is contained in $\mathbb{R}[V^k]^G$.

For most $G$-representations $V$, classical polarizations do \textit{not} generate $\mathbb{R}[V^k]^G$. It is conjectured, for example, that for $G$ finite, $\mathbb{R}[V^2]^G$ can only be generated by classical polarizations if $G$ is generated by reflections, see \cite{Sch07} and Remark 35 below for a more complete discussion. In contrast, one has:

\textbf{Theorem D.} Let $V$ be a real orthogonal representation of the finite group $G$, and $k \geq 2$. Then the algebra of invariants of the $G$-representation $V^k$ is generated by generalized polarizations.

Theorem D is an immediate consequence of Theorem C and the fact that classical polarizations separate $G$-orbits in $V^k$ for finite $G$, see \cite{DKW08} Theorem 3.4.

For the next application, assume for simplicity that the $G$-representation $V$ is faithful, so that we may treat $G$ as a subgroup of the orthogonal group $O(V)$. If $G$ is infinite, one faces a new difficulty in that a different subgroup $G'$ may have the same orbits as $G$, so that in particular $\mathbb{R}[V]^G = \mathbb{R}[V]^{G'}$. Such a pair of groups are called \textit{orbit-equivalent}, the simplest example being $SO(n)$ and $O(n)$ acting on $\mathbb{R}^n$ for $n > 1$. In such a case, $\mathbb{R}[V^k]^G$ and $\mathbb{R}[V^k]^{G'}$ will necessarily be different for $k$ large enough. Therefore, no procedure that produces elements of $\mathbb{R}[V^k]^G$ out of $\mathbb{R}[V]^G$ can possibly be enough to generate all of $\mathbb{R}[V^k]^G$ for a general subgroup $G$. To fix this, we impose the condition that $G$ be maximal (with respect to inclusion) in its orbit-equivalence class, and obtain:

\textbf{Theorem E.} Let $G$ be a compact subgroup of $O(V)$, maximal in its orbit-equivalence class, and $k \geq 2$. Assume one of the following conditions is satisfied:

(a) the connected component of $G$ is a torus;
(b) $k \geq \dim(V)$;

Then the algebra of invariants of the $G$-representation $V^k$ is generated by generalized polarizations.

The extra conditions (a), (b) above are technical, and the authors do not know if they are necessary:

\textit{Question 1.} Let $G$ be a compact subgroup of $O(V)$, maximal in its orbit-equivalence class, and $k \geq 2$. Is the algebra of invariants of the $G$-representation $V^k$ generated by generalized polarizations?

Finally, we mention that generalized polarizations can be used to give a sufficient criterion for a manifold submetry to be homogeneous, see Subsection 5.4.

\textbf{Maximality of Laplacian algebras.} In addition to being a generalization of orbit decompositions, the fibers of manifold submetries also generalize classical objects from Foliations Theory, such as: \textit{transnormal systems}; \textit{singular Riemannian foliations}; and \textit{isoparametric foliations}, that is, the foliation given by the parallel and focal submanifolds of isoparametric submanifolds. In particular, there exist...
many important examples of infinitesimal manifold submetries which are inhomogeneous, that is, not given by the orbits of some orthogonal action by a compact group.

The “Invariant Theory” of infinitesimal manifold submetries has its roots in the study, by many authors, of the algebraic aspects of singular Riemannian foliations and isoparametric foliations of Euclidean space. A crucial ingredient is that, like in the homogenous case, $B(\sigma)$ separates fibers. An early version of this was proved for isoparametric foliations in [M"un80, M"un81], then for singular Riemannian foliations in [LR18], and later for general manifold submetries in [MR20b]. In fact, Theorem A has an almost identical statement to [MR20b, Theorem A], in which the algebras in [LR18], and later for general manifold submetries in [MR20b]. In fact, Theorem A has an almost identical statement to [MR20b, Theorem A], in which the algebras are required to be both Laplacian and maximal.

To define maximality, note that any $A \subset \mathbb{R}[V]$ defines an equivalence relation $\sim_A$ on $V$ where $x \sim_A y$ if and only if $f(x) = f(y)$ for all $f \in A$. Then we say that a sub-algebra $A \subset \mathbb{R}[V]$ is maximal if any strictly larger algebra would define an equivalence relation strictly finer than $\sim_A$. It was conjectured in [MR20b] that Laplacian implies maximal, and the solution of this conjecture is the technical heart of the present paper:

**Theorem F.** Let $A \subset \mathbb{R}[V]$ be a Laplacian algebra. Then $A$ is maximal.

**Sketch of the proofs.** To prove that a Laplacian algebra $A$ is maximal (Theorem F), we consider the unit sphere $SV$ in $V$, and its quotient $X = SV/\sim_A$ by the equivalence relation given by $A$ as above. Then $A$ is an algebra of continuous functions on the compact Hausdorff topological space $X$, which separates points of $X$ by definition, so the Stone–Weierstrass Theorem implies that $A$ is dense in $C^0(X)$.

Assuming $A$ is not maximal, there is a homogeneous polynomial $f \not\in A$ that is constant on the equivalence classes of $\sim_A$, and hence descends to a continuous function on $X$. The fact that $A$ is Laplacian means that $A$ is compatible with the Theory of Spherical Harmonics. This implies that $f$ may be taken orthogonal to $A$ in the appropriate sense, and that the induced element of $C^0(X)$ is orthogonal to $A$ in the $L^2$ inner product, contradicting density of $A$.

Theorems A, B, and C follow from Theorem F and [MR20b], and Theorem D follows from Theorem C and [DKW08, Theorem 3.4].

We turn to Theorem E under condition (a), the proof under condition (b) being analogous. Thus let $G \subset O(V)$ be maximal in its orbit-equivalence class, and assume its connected component is a torus. Let $A = \mathbb{R}[V]^G$, and $k \geq 2$. By a local version of Theorem C (Theorem 16 below), it is enough to show that $A^{(k)}$ generically separates $G$-orbits, because $A^{(k)}$ is Laplacian by definition.

For simplicity, assume $k = 2$. Given $(x, y), (z, w) \in V^2$ such that $F(x, y) = F(z, w)$ for all $F \in A^{(2)}$, we need to find $g \in G$ such that $g(x, y) = (z, w)$. Since $A^{(2)}$ contains all inner products by definition, we have $\|x\| = \|z\|$, $\|y\| = \|w\|$, and $\langle x, y \rangle = \langle z, w \rangle$, and so there exists $g \in O(V)$ such that $g(x, y) = (z, w)$. Making $F$ run through all classical polarizations, the original definition given by (1) shows that $f(sx + ty) = f(sz + tw)$ for all $f \in A$, so that $sx + ty$ and $g(sx + ty)$ belong to the same $G$-orbit, for all $s, t \in \mathbb{R}$.

A similar argument using generalized polarizations instead of classical polarizations yields $g \in O(V)$ such that $g(x, y) = (z, w)$, and such that $\nabla f(x) + \nabla h(y)$ and $g(\nabla f(x) + \nabla h(y))$ belong to the same $G$-orbit for all $f, h \in A$. But the facts that the connected component of $G$ is a torus and that $(x, y)$ is generic imply that
every $v \in V$ can be written in the form $\nabla f(x) + \nabla h(y)$ for appropriate choices of $f, h$. Thus $g \in O(V)$ takes every $G$-orbit to itself, which implies $g \in G$ because $G$ is maximal in its orbit-equivalence class.

**Organization of the paper.** In Section 2 we recall some basic definitions, and the theory of Spherical Harmonics, and give a proof of Theorem F. Section 3 contains definitions involving submetries, and the proofs of Theorems A, B. In Section 4 we introduce the notion of local separating set, prove Theorem C, and illustrate how it can be used to prove First Fundamental Theorems. Section 5 is devoted to the study of generalized polarizations. It includes the proof of Theorem E and of a sufficient criterion for a manifold submetry to be homogeneous.

**Acknowledgements.** It is a pleasure to thank Harm Derksen for pointing out [Sch08], which was the main inspiration for the proof of Theorem F, and Matyas Domokos for a simplification of the proof of Theorem D using [DKW08]. We would also like to thank Alexander Lytchak and Matyas Domokos for suggestions that improved the exposition.

2. LAPLACIAN ALGEBRAS ARE MAXIMAL

This section is devoted to the proof of Theorem F, given in Subsection 2.5. To fix notations and for the sake of completeness, the definitions and basic facts needed in the proof are laid out in the first four subsections. The material in Subsections 2.1 and 2.2 is well-known, see for example [HT92, Exercise 12(e), page 118] or [Hel00, Introduction, Section 3]. The material in Subsections 2.3 and 2.4 is either contained in, or follows easily from, [MR20b].

2.1. Polynomials. Let $V$ be a Euclidean vector space, that is, a real finite-dimensional vector space with inner product $\langle \cdot, \cdot \rangle$ (which we will occasionally write $\langle \cdot, \cdot \rangle_V$), and denote by $O(V)$ the corresponding orthogonal group.

Let $\mathbb{R}[V]$ be the algebra of polynomial functions $V \to \mathbb{R}$, which is graded in the sense that

$$\mathbb{R}[V] = \bigoplus_{d=0}^{\infty} \mathbb{R}[V]_d$$

where $\mathbb{R}[V]_d$ denotes the space of homogeneous polynomials of degree $d$. The group $O(V)$ acts on $\mathbb{R}[V]$ by $(Uf)(v) = f(U^{-1}v)$ for $f \in \mathbb{R}[V]$ and $U \in O(n)$, and this action preserves the grading.

Choose an orthonormal basis $e_1, \ldots, e_n$ of $V$, and dual basis $x_1, \ldots, x_n$ of $V^*$. In particular we have an identification of $\mathbb{R}[V]$ with $\mathbb{R}[x_1, \ldots, x_n]$, and of $O(V)$ with the group of orthogonal $n \times n$ matrices $O(n)$.

Given $f \in \mathbb{R}[V]_d$, its dual is the differential operator $\hat{f}$, of order $d$, obtained from $f$ by replacing each variable $x_i$ with the partial derivative $\frac{\partial}{\partial x_i}$, and products with composition. Define a bilinear form $\langle \cdot, \cdot \rangle_d$ on each $\mathbb{R}[V]_d$ by

$$\langle f, g \rangle_d = \hat{f}(g).$$

It is not hard to see that this is an inner product, that the monomials $x_1^{\alpha_1} \cdots x_n^{\alpha_n}$ (where $\alpha_i \geq 0$ and $\alpha_1 + \cdots + \alpha_n = d$) form an orthogonal basis, and that $\|x_1^{\alpha_1} \cdots x_n^{\alpha_n}\|_2^2 = \alpha_1! \cdots \alpha_n!$. Note also that the dual operation satisfies $\hat{f} \hat{g} = \hat{g} \hat{f}$, so in particular multiplication with a polynomial $h$ is adjoint to $\hat{h}$. More precisely, for every
triple of homogeneous polynomials with \( \deg(fh) = \deg(g) \), one has \( \langle hf, g \rangle_{\deg(g)} = \langle f, h(g) \rangle_{\deg(f)} \).

**Lemma 2.** The inner product \( \langle , \rangle_{d} \) on \( \mathbb{R}[V]_{d} \) defined in (2) above is \( O(V) \)-invariant.

**Proof.** \( \mathbb{R}[V]_{d} \) is isomorphic, as an \( O(V) \)-representation, to the space of symmetric tensors \( \text{Sym}^{d}(V^{*}) \), that is, to the subspace of all elements of \( (V^{*})^{\otimes d} \) that are fixed by the natural action of the permutation group \( S_{d} \). Namely, the multilinear map \( \alpha \in \text{Sym}^{d}(V^{*}) \) corresponds to the polynomial function \( f = \phi(\alpha) \) given by \( f(v) = \alpha(v, \ldots, v) \).

The inner product on \( V \) induces a natural inner product on \( V^{*} \), which we also denote by \( \langle , \rangle \), which then induces the following inner product on \( (V^{*})^{\otimes d} \), which is clearly \( O(V) \)-invariant:

\[
\langle \lambda_{1} \otimes \cdots \otimes \lambda_{d}, \mu_{1} \otimes \cdots \otimes \mu_{d} \rangle = \langle \lambda_{1}, \mu_{1} \rangle \cdots \langle \lambda_{d}, \mu_{d} \rangle.
\]

Thus it suffices to show that \( \langle \phi(\alpha), \phi(\beta) \rangle_{d} = d! \langle \alpha, \beta \rangle \) for all \( \alpha, \beta \in \text{Sym}^{d}(V^{*}) \). To this end, note that \( x_{1}^{\alpha_{1}} \cdots x_{n}^{\alpha_{n}} = \phi(\alpha) \) with

\[
\alpha = \frac{1}{d!} \sum_{\sigma \in S_{d}} \sigma((x_{1})^{\otimes \alpha_{1}} \otimes \cdots \otimes (x_{n})^{\otimes \alpha_{n}})
\]

and that

\[
\langle \alpha, \alpha \rangle = \frac{1}{(d!)^{2}} \sum_{\sigma, \tau \in S_{d}} \langle \sigma((x_{1})^{\otimes \alpha_{1}} \otimes \cdots \otimes (x_{n})^{\otimes \alpha_{n}}), \tau((x_{1})^{\otimes \alpha_{1}} \otimes \cdots \otimes (x_{n})^{\otimes \alpha_{n}}) \rangle
\]

which equals \( \frac{\alpha_{1}^{\cdots} \cdot \alpha_{d}}{d!} \).

2.2. Harmonic polynomials. We keep the same notations as in the previous subsection. Let \( r^{2} \) denote the quadratic polynomial

\[
r^{2} = x_{1}^{2} + \cdots + x_{n}^{2} \in \mathbb{R}[V],
\]

and let \( \Delta \) denote the Laplace operator

\[
\Delta = \hat{r}^{2} = \frac{\partial^{2}}{\partial x_{1}^{2}} + \cdots + \frac{\partial^{2}}{\partial x_{n}^{2}}.
\]

For each \( d \geq 0 \), let \( \mathcal{H}_{d} \) denote the subspace of \( \mathbb{R}[V]_{d} \) consisting of the harmonic polynomials, that is, polynomials \( f \) satisfying \( \Delta(f) = 0 \). Then one has the following \( \langle , \rangle_{d} \)-orthogonal direct sum decomposition of \( \mathbb{R}[V]_{d} \).

\[
\mathbb{R}[V]_{d} = \mathcal{H}_{d} \oplus r^{2}\mathcal{H}_{d-2} \oplus \cdots \oplus r^{2(d/2)}\mathcal{H}_{d-2(d/2)}
\]

The summands above are also the irreducible components of \( \mathbb{R}[V]_{d} \) as an \( O(V) \)-representation, and they are pairwise inequivalent. These facts are usually called the theory of spherical harmonics, see for example [HT92 Exercise 12(e), page 118].

Another, more geometric, inner product one can define on \( \mathbb{R}[V]_{d} \) is the \( L^{2} \)-product given by

\[
\langle f, g \rangle_{L^{2}} = \int_{SV} fg \, d\text{vol}
\]

where \( SV \) denotes the unit sphere in \( V \), and \( d\text{vol} \) its natural Riemannian volume form. Since this inner product is also \( O(V) \)-invariant, we can apply Schur’s Lemma.
to conclude that there exist positive constants $C^d_i$ such that

\[(4)\] 

\[\langle f, g \rangle_{L^2} = \sum_{i=0}^{\lfloor d/2 \rfloor} C^d_i \langle f_i, g_i \rangle_d\]

according to the decomposition of $f, g \in \mathbb{R}[V]_d$ in (3). That is, $f = \sum_i f_i$, and $g = \sum_i g_i$, with $f_i, g_i \in r^i \mathcal{H}_{d-2i}$.

2.3. Laplacian algebras. Laplacian algebras were introduced in [MR20b]:

**Definition 3.** Let $A \subset \mathbb{R}[V]$ be a sub-algebra. It is called Laplacian if it contains $r^2$ and is preserved by the Laplace operator $\Delta$.

**Lemma 4.** Let $A \in \mathbb{R}[V]$ be a Laplacian algebra. Then

(a) $A$ is graded, that is,

\[A = \bigoplus_{d=0}^{\infty} A_d,\]

where $A_d = A \cap \mathbb{R}[V]_d$.

(b) Each $A_d$ is graded with respect to the decomposition in (3):

\[A_d = (A_d \cap \mathcal{H}_d) \oplus (A_d \cap r^2 \mathcal{H}_{d-2}) \oplus \cdots \oplus (A_d \cap r^{2\lfloor d/2 \rfloor} \mathcal{H}_{d-2\lfloor d/2 \rfloor}).\]

**Proof.** (a) Since $A$ is preserved by $\Delta$ and by multiplication with $r^2$, it is preserved by the Lie bracket $[\Delta, r^2]$ of these two linear maps. The latter is a linear endomorphism of $\mathbb{R}[V]$ with eigenspaces $\mathbb{R}[V]_d$, so $A$ is graded.

(b) Note that the $(\cdot, \cdot)_d$-orthogonal complement of $r^2 A_{d-2}$ in $A_d$ is exactly $A_d \cap \mathcal{H}_d$. Indeed, $f \in A_d$ is orthogonal to $r^2 A_{d-2}$ if and only if $\Delta(f) = 0$, because $\Delta(f)$ is an element of $A_{d-2}$ that satisfies $\langle \Delta(f), g \rangle_{d-2} = \langle f, r^2 g \rangle_d$ for all $g \in A_{d-2}$.

The result now follows by induction. \(\square\)

2.4. Partitions of vector spaces and maximal algebras. Given a sub-algebra $A \subset \mathbb{R}[V]$ (or, in fact, any subset), define the equivalence relation $\sim_A$ on $V$ by

\[v \sim_A w \iff f(v) = f(w) \quad \forall f \in A\]

In words, $v, w$ are equivalent if and only if they cannot be separated by any element of $A$.

Denote by $\mathcal{L}(A)$ the partition of $V$ into the equivalence classes (also called leaves) of $\sim_A$. The symbol $\mathcal{L}$ stands for Level sets, because the elements of $\mathcal{L}(A)$ are the common level sets of polynomials in $A$.

In the opposite direction, given a partition $\mathcal{F}$ of $V$, we define the sub-algebra $\mathcal{B}(\mathcal{F}) \subset \mathbb{R}[V]$ as the algebra of all $\mathcal{F}$-basic polynomials, that is, polynomials that are constant on the leaves of $\mathcal{F}$.

Given a partition $\mathcal{F}$ of $V$, a subset of $V$ is called $\mathcal{F}$-saturated if it is a union of $\mathcal{F}$-leaves. Partially order partitions by $\mathcal{F} \prec \mathcal{F}'$ when $\mathcal{F}$ is coarser than $\mathcal{F}'$, that is, when every $\mathcal{F}$-leaf is $\mathcal{F}'$-saturated. On the other hand, we partially order sub-algebras of $\mathbb{R}[V]$ by inclusion. Then both $\mathcal{L}$ and $\mathcal{B}$ preserve these partial orders. Moreover, one has the tautologies $A \subset \mathcal{B}(\mathcal{L}(A))$ and $\mathcal{L}(\mathcal{B}(\mathcal{F})) < \mathcal{F}$. In particular, $\mathcal{B} \circ \mathcal{L} \circ \mathcal{B} = \mathcal{B}$ and $\mathcal{L} \circ \mathcal{B} \circ \mathcal{L} = \mathcal{L}$.
Definition 5 ([MR200]). A sub-algebra $A \subset \mathbb{R}[V]$ is called maximal if $A = \mathcal{B}(\mathcal{L}(A))$, or, equivalently, if it is the algebra of basic polynomials of some partition of $V$.

Lemma 6. Let $A \subset \mathbb{R}[V]$ be a graded sub-algebra. Then $B = \mathcal{B}(\mathcal{L}(A))$ is also graded.

Proof. Since $A$ is graded, the homothetic transformations $h_\lambda : V \to V$ (defined by $h_\lambda(v) = \lambda v$) send $\mathcal{L}(A)$-leaves onto $\mathcal{L}(A)$-leaves, for all $\lambda \in \mathbb{R} \setminus \{0\}$.

Let $f \in B$ be a polynomial of degree $d$, and, for each $i = 0, \ldots, d$, let $f_i$ be its homogeneous component of degree $i$. Thus $f = \sum_{i=0}^{d} f_i$ and so

$$
\lambda^{-d} f \circ h_\lambda = \lambda^{-d} f_0 + \cdots + \lambda^{-1} f_{d-1} + f_d \in B
$$

for all $\lambda \neq 0$. Taking $\lambda \to \infty$ shows that $f_d \in B$, so that $f - f_d \in B$, and one can proceed by induction on the degree of $f$. \hfill \Box

2.5. Laplacian algebras are maximal.

Proof of Theorem [7]. Let $B = \mathcal{B}(\mathcal{L}(A))$. Assume for a contradiction that the inclusion $A \subset B$ is strict. By Lemmas [3] and [5] the algebras $A$ and $B$ are graded, so there exists $d$ such that the inclusion $A_d \subset B_d$ is strict. Let $f \in B_d \setminus \{0\}$ orthogonal to $A_d$ with respect to the inner product $\langle \cdot, \cdot \rangle_d$ defined in [2].

Let $X = SV/\sim_A$ be the quotient topological space of the unit sphere $SV \subset V$ by the equivalence relation $\sim_A$, which restricts to $SV$ because $r^2 \in A$. Since $SV$ is compact, so is $X$. Let $C^0(X)$ denote the algebra of continuous real-valued functions on $X$, and consider the algebra homomorphism

$$
\varphi : B \to C^0(X)
$$

where, given $h \in B$, $\varphi(h)$ is the function on $X$ induced by the restriction $h|_{SV} : SV \to \mathbb{R}$.

Then $\varphi(A)$ is a sub-algebra of $C^0(X)$ which separates points, and contains the constant functions. By the Stone–Weierstrass Theorem (see [Rud76] Theorem 7.32 on page 162) $\varphi(A)$ is dense in $C^0(X)$ with respect to the supremum norm.

Since $f$ is homogeneous and non-zero, we have $\int_{SV} f^2 d\text{vol} > 0$. Choose $g \in A$ such that the $C^0$-distance

$$
\sup_{x \in X} |\varphi(g)(x) - \varphi(f)(x)| = \sup_{v \in SV} |g(v) - f(v)|
$$

is small enough so that

$$
\int_{SV} f g d\text{vol} > 0.
$$

Assume $d = \deg f$ even. (The case $d$ odd is analogous and is left to the reader.) Since $f|_{SV}$ is an even function, we may assume $g$ is also even, that is, has only even degree homogeneous components, because the $C^0$-distance between $f|_{SV}$ and the even part of $g|_{SV}$ is at most the $C^0$-distance between $f|_{SV}$ and $g|_{SV}$. Thus, by multiplying the homogeneous components of $g$ with appropriate powers of $r^2$, we may assume $g$ homogeneous, and $\deg(g)$ is an even number $\geq d$.

On the other hand, for any $k$, the polynomial $r^{2k} f$ is a non-zero element of $B_{d+2k}$ which is $\langle \cdot, \cdot \rangle_{d+2k}$-orthogonal to $A_{d+2k}$, because $A$ is Laplacian. Therefore, we may assume $f, g$ are homogeneous of the same (even) degree $d$. 

Decompose \( f, g \) with respect to (3). That is, \( f = \sum_i f_i \), and \( g = \sum_i g_i \), with \( f_i, g_i \in \mathcal{H}_{d-2i} \). By Lemma 4, \( g_i \in A_d \) for every \( i \). Since \( f \) is orthogonal to \( A_d \), Lemma 4 implies that each \( f_i \) is orthogonal to \( A_d \). Thus, by (4), we obtain \( \int_{SV} f g \, d\text{vol} = 0 \), contradicting (5).

3. Manifold submetries

For more information on submetries and manifold submetries, see [KL 20, MR20b] and references therein.

**Definition 7.**

- A *submetry* is a map between metric spaces which maps closed metric balls to closed metric balls of the same radius.
- A *manifold submetry* is a submetry from a Riemannian manifold to a metric space, such that each fiber is a possibly disconnected embedded smooth submanifold.
- A *spherical manifold submetry* is a manifold submetry from the unit sphere \( SV \) in a Euclidean vector space \( V \).
- An *infinitesimal manifold submetry* is a manifold submetry from a Euclidean vector space \( V \), such that the origin is a fiber.

We note the fibers of a submetry form a partition of the domain into closed equidistant subsets, and that, conversely, any such partition comes from a submetry. We also note that, given an infinitesimal manifold submetry \( \sigma : V \to X \), the unit sphere \( SV \) is a union of fibers, and the restriction \( \sigma|_{SV} : SV \to \sigma(SV) \) is a spherical manifold submetry. Moreover, this procedure establishes a one-to-one correspondence between these two types of manifold submetries, see [MR20b, Appendix B1].

**Example 8.** Let \( G \) be a compact group, and \( V \) be an orthogonal \( G \)-representation. Then the quotient map \( V \to V/G \) is an infinitesimal manifold submetry, and \( SV \to SV/G \) is a spherical manifold submetry.

**Definition 9.** Given an infinitesimal manifold submetry \( \sigma : V \to X \), denote by \( \mathcal{F}_\sigma \) the partition of \( V \) into the fibers of \( \sigma \), and define its *algebra of basic polynomials* by \( B(\sigma) = B(\mathcal{F}_\sigma) \).

We will frequently abuse notation and write “let \((V, \mathcal{F})\) be a manifold submetry” when we mean “let \( \sigma : V \to X \) be a manifold submetry, and \( \mathcal{F} = \mathcal{F}_\sigma \)”.

**Proof of Theorem A** By [MR20b, Theorem A], \( \sigma \mapsto B(\sigma) \) gives a one-to-one correspondence between infinitesimal manifold submetries (modulo the equivalence relation of having the same fibers), and maximal Laplacian sub-algebras of \( \mathbb{R}[V] \). By Theorem F, the maximality condition is superfluous, because it follows from Laplacian.

Analogously, the word “maximal” can also be removed from the statements of [MR20b, Theorems B and C]:

**Corollary 10.** Let \( A \subset \mathbb{R}[V] \) be a sub-algebra. Then

(a) \( A \) is the algebra of invariants of a finite subgroup \( G \subset O(V) \) if and only if \( A \) is Laplacian and the field of fractions of \( A \) has transcendence degree (over \( \mathbb{R} \)) equal to \( \dim(V) \).
(b) $A$ is the algebra of basic polynomials of a transnormal system if and only if $A$ is Laplacian and integrally closed in $\mathbb{R}[V]$.

4. Separating versus generating invariants

In this section we prove a result (Theorem 16 below) that generalizes Theorem C in two directions: the orthogonal representation is replaced with a manifold submetry, and the set $S$ is only assumed to separate leaves on a certain open set.

**Definition 11.** Let $σ : V \to X$ be an infinitesimal manifold submetry, and $S ⊂ B(σ)$ a subset of the algebra $B(σ)$ of basic polynomials.

- The set $S$ is called a **separating set** for $σ$ if it separates the fibers of $σ$, that is, if $\mathcal{L}(S) = \mathcal{F}_σ$.
- The set $S$ is called a **local separating set** for $σ$ if there exists an open subset $U \subset V$ with the following properties. (1) $U$ is $\mathcal{L}(S)$-saturated, hence also $\mathcal{F}_σ$-saturated. And (2) $S$ separates fibers of $σ$ contained in $U$, that is, $\mathcal{L}(S)|_U = \mathcal{F}_σ|_U$.

**Example 12.** To illustrate the requirement that the open set $U$ be saturated with respect to both $\mathcal{L}(S)$ and $\mathcal{F}_σ$ in the definition above, consider $V = X = \mathbb{R}$, and $σ = \text{Id}$. Then the leaves of $\mathcal{F}_σ$ are points, and every polynomial on $V$ is $σ$-basic, so $B(σ) = \mathbb{R}[t]$. The set $S = \{t^2\}$ separates fibers of $σ$ contained in $U = (0, \infty)$, an open set which is $\mathcal{F}_σ$-saturated but not $\mathcal{L}(S)$-saturated. In fact, $S$ is not a local separating set for $σ$.

In the context of group actions, sets of separating invariants have been intensely studied in the recent past, see [DK15 Section 2.4] and references therein.

**Lemma 13.** Let $S ⊂ \mathbb{R}[V]$ be a subset containing $r^2$. Then the sub-algebra $B ⊂ \mathbb{R}[V]$ generated by $S$ is Laplacian if and only if $\Delta f$ and $⟨\nabla f, \nabla g⟩$ belong to $B$, for every $f, g ∈ S$.

**Proof.** See [MR20a] Proposition 37. □

**Remark 14.** Suppose $A$ is an algebra containing $r^2$ and generated by homogeneous polynomials of degree 2, and let $A_2$ be its degree two graded part. Then, identifying $V = \mathbb{R}^n$ and quadratic polynomials $f ∈ \mathbb{R}[V]_2$ with the symmetric matrices $\text{Hess}(f)/2 ∈ \text{Sym}^2(\mathbb{R}^n)$, Lemma 13 implies that $A$ is Laplacian if and only if $A_2$ is closed under the standard Jordan product on $\text{Sym}^2(\mathbb{R}^n)$ given by $M ⊗ N = (MN + NM)/2$. This observation leads to a classification of Laplacian algebras generated by quadratic polynomials: they are essentially the ones given in Examples 17 and 19 below — see [MR20a].

**Lemma 15.** Let $F, F'$ be the decompositions of $V$ into the fibers of infinitesimal manifold submetries $σ, σ'$ from $V$, and let $U ⊂ V$ be an open subset which is both $F$- and $F'$-saturated. If $F|_U = F'|_U$, then $F = F'$.

**Proof.** Let $x, y ∈ V$ on the same $F$-leaf. Let $L ⊂ U$ an $F$-, hence also $F'$-leaf. Take a minimizing geodesic $γ : [0, l] → V$ from $x$ to $L$, with $γ(0) = x$, and $γ(l) ∈ L$. Choose a vector $v ∈ T_yV$ whose image in (the appropriate space of directions in) the quotient $V/F$ coincides with the image of $γ'(0)$.

By [MR20a] Proposition 14(4)], $γ(t)$ and $y + tv$ belong to the same $F$-leaf for all $t$. In particular, there is $ε > 0$ such that, for all $t ∈ (l - ε, l + ε)$, the points $γ(t)$
and $y + tv$ belong to the same $F'$-leaf. Thus $\gamma'(l)$ and $v \in T_{y+tv}$ map to the same vector in $V/F'$.

Applying [MR20b Proposition 14(4)] again, we conclude that $x = \gamma(0)$ and $y$ belong to the same $F'$-leaf.

Thus $F'$ is coarser than $F$. Reversing the roles of $F, F'$ in the argument above yields $F$ coarser than $F'$, therefore $F = F'$.

**Theorem 16.** Let $\sigma$ be an infinitesimal manifold submetry from $V$, and $S$ a local separating set for $\sigma$ containing $r^2$. Then the sub-algebra $B \subset \mathbb{R}[V]$ generated by $S$ coincides with $B(\sigma)$ if and only if $\Delta f$ and $\langle \nabla f, \nabla g \rangle$ belong to $B$, for every $f, g \in S$.

**Proof.** Suppose $B = B(\sigma)$. Then, by [MR20b Theorem A], $B$ is Laplacian, and therefore $\Delta f$ and

$$\langle \nabla f, \nabla g \rangle = \frac{\Delta(fg) - f \Delta g - g \Delta f}{2}$$

belong to $B$, for every $f, g \in S$.

For the converse implication, assume $\Delta f$ and $\langle \nabla f, \nabla g \rangle$ belong to $B$, for every $f, g \in S$. By Lemma 15, $B$ is a Laplacian algebra. By Theorem A, $B = B(\sigma')$ for some manifold submetry $\sigma'$.

Denoting by $F, F'$ the fiber decompositions associated to $\sigma, \sigma'$, the fact that $S \subset B \subset B(\sigma)$ implies that $\mathcal{L}(S) < F' < F$ (recall that “$<$” means “coarser than”).

By definition of local separating, there exists an $\mathcal{L}(S)$-saturated open subset of $V$ (hence both $F$-, and $F'$-saturated) such that $\mathcal{L}(S)|_U = F|_U$. Thus $F'|_U = F|_U$, which, by Lemma 15 implies that $F' = F$. In particular, $B = B(F') = B(F) = B(\sigma)$. □

**Proof of Theorem C.** Follows immediately from Theorem 16 where the infinitesimal manifold submetry $\sigma$ is taken to be the quotient map $V \to V/G$. □

**4.1. Applications to First Fundamental Theorems.** We collect here a few simple examples which illustrate how Theorems C and 16 can be used to prove First Fundamental Theorems, that is, to prove that certain sets of invariant (respectively basic) polynomials actually generate the algebra of all invariant (respectively basic) polynomials. Our method is loosely analogous to the method illustrated in [Sch08 Section 5] to prove FFT’s for general tensors (as opposed to symmetric tensors, that is, polynomials).

**Example 17.** The standard diagonal action of $G = O(n)$ (respectively, $U(n), \text{Sp}(n)$) on $V = (\mathbb{R}^n)^k$ (respectively $(\mathbb{C}^n)^k$, $(\mathbb{H}^n)^k$). Generators for the algebra of invariants $\mathbb{R}[V]^G$ are given by the polynomials $f_{ij}(v_1, \ldots, v_n) = (v_i, v_j)$, and similarly in the complex and quaternionic cases. This is sometimes called Weyl’s First Fundamental Theorems for $O(n)$ (respectively $U(n), \text{Sp}(n)$), see [Wey97].

Indeed, these polynomials are clearly $G$-invariant, and it is an elementary fact in Linear Algebra that they separate the $G$-orbits. Moreover, being quadratic polynomials, it follows that $\Delta(f_{ij})$ are constant, hence belong to the algebra generated by $f_{ij}$. Finally, a simple computation shows that $\langle \nabla f_{ab}, \nabla f_{cd} \rangle$ belongs to the span of $\{f_{ij}\}$ for every $a, b, c, d$.

**Example 18.** The standard diagonal action of $G = \text{SO}(n)$ on $V = (\mathbb{R}^n)^k$. A set of generators for $\mathbb{R}[V]^G$ is given by the $f_{ij}$ from the previous example when $k < n$. 
If $k \geq n$, one needs to add certain polynomials $h_S$, one for each $n$-element subset $S = \{s_1, \ldots, s_n\} \subset \{1, \ldots, k\}$, defined by $h_S(v_1, \ldots, v_k) = \det(v_{s_1}, \ldots, v_{s_n})$.

Indeed, it is easy to see that these polynomials are $G$-invariant, and separate $G$-orbits. Moreover, $\Delta h_S = 0$ because each variable only appears once, and $\langle \nabla h_S, \nabla h_T \rangle$, being $O(n)$-invariant, can be written as polynomials in the $f_{ij}$, by the previous example. Finally, the fact that the gradient of the determinant function is the adjugate matrix, together with Cramer’s rule, shows that $\langle \nabla f_{ij}, \nabla h_S \rangle$ vanishes if $\{S \cap \{i, j\}\} = 0$ or 2, and equals $\pm h_{j \cup S \cap i}$ if $i \in S$ and $j \notin S$.

**Example 19.** Clifford foliations. Let $P_0, \ldots, P_m$ be a Clifford system, that is, a set of $2l \times 2l$ real symmetric matrices such that $P_i^2 = I$ for every $i$, and $P_i P_j = -P_j P_i$ for every $i \neq j$. The associated Clifford foliation in $\mathbb{R}^{2l}$ is defined as $\mathcal{L}(\{r^2, f_0, \ldots, f_m\})$, where $f_i(x) = \langle P_i x, x \rangle$, see [Rad14]. Then the algebra of basic polynomials is generated by the quadratic polynomials $r^2, f_0, \ldots, f_m$. (This was originally proved in [MR20a], with a considerably more complicated argument.)

Indeed, they separate leaves by definition, their Laplacians are constant, and $\langle \nabla f_i, \nabla f_j \rangle(x) = \langle (P_i P_j + P_j P_i)x, x \rangle$, which equals either 0 or $2 \|x\|^2$, according to whether $i \neq j$ or $i = j$.

5. Polarizations

Polarizations are a classical tool in Invariant Theory, used to produce multi-variable invariants from single-variable invariants. We introduce a generalization and show that in many situations these “generalized polarizations” are enough to generate all multi-variable invariants. For a general reference on (classical) polarizations, see [KP90] Section 7.1 and [Wey97].

5.1. Definitions.

**Definition 20.** Let $S$ be an arbitrary subset of $\mathbb{R}[V]$. The Laplacian sub-algebra generated by $S$ is defined to be the smallest Laplacian sub-algebra $A$ of $\mathbb{R}[V]$ that contains $S$. That is, $A$ is the intersection of all Laplacian sub-algebras of $\mathbb{R}[V]$ containing $S$.

**Remark 21.** In the notation of Remark 14 if the elements of $S$ are homogeneous polynomials of degree two, then the Laplacian algebra generated by $S$ is the sub-algebra of $\mathbb{R}[V]$ generated by the smallest Jordan sub-algebra of $\text{Sym}^2(\mathbb{R}^n) \cong \mathbb{R}[V]_2$ containing $S$ and $\text{Id}$.

**Remark 22.** If $S$ generates $A$ as a Laplacian algebra as in the definition above, one can produce a larger set which generates $A$ as an algebra in the following way. In particular, if $S$ is a local separating set for an infinitesimal manifold submetry $\sigma$, this produces a generating set for $A = B(\sigma)$ by Theorem 15.

Let $S_l = S \cup \{r^2\}$. For $l \geq 2$, define $T_l$ as all the elements of

$$\Delta S_{l-1} \cup \{\langle \nabla f, \nabla h \rangle \mid f, h \in S_{l-1}\}$$

that do not belong to the algebra generated by $S_{l-1}$, and define $S_l = S_{l-1} \cup T_l$.

Then $\bigcup_{l=1}^{\infty} S_l$ generates $A$ as an algebra by Lemma 13. Moreover, since $A$ is finitely generated by [MR20a] Lemma 24, the nested sequence $S_l$ stabilizes, and $A$ is generated, as an algebra, by $S_l$ for some $l$ that depends only on $S$. 

R. MENDES AND M. RADESCHI
Definition 23. Let $A \subset \mathbb{R}[V]$ a Laplacian sub-algebra, associated to the infinitesimal manifold submetry $\mathcal{F}$, and $k \geq 1$ an integer. The algebra of generalized polarizations on $V^k$, denoted $A^{(k)}$, is the Laplacian sub-algebra of $\mathbb{R}[V^k]$ generated by the polynomials $f_{ij}(v_1, \ldots, v_k) = \langle v_i, v_j \rangle$, and the polynomials $(v_1, \ldots, v_k) \mapsto f(v_1)$, for all $f \in A$.

Denote by $\mathcal{F}^{(k)}$ the infinitesimal manifold submetry of $V^k$ corresponding to $A^{(k)}$ according to Theorem [A]

Note that the subspaces $V_1 = V \times \{0\} \times \cdots \times \{0\}$, $V_2 = \{0\} \times V \times \{0\} \times \cdots \times \{0\}$, etc are $\mathcal{F}^{(k)}$-saturated (also called $\mathcal{F}^{(k)}$-invariant). In particular, $A^{(k)}$ is multi-graded with respect to the product structure of $V^k$, by [MR20a] Proposition 19.

Note also that, if $\mathcal{F}$ is homogeneous, given by the orbits of some $G \subset O(V)$, then $A^{(k)}$ is contained in the algebra of invariants $\mathbb{R}[V^k]^G$, where $G$ acts on $V^k$ diagonally. In particular, $A \mapsto A^{(k)}$ can be seen as a procedure that produces a set of multi-variable invariants from the single-variable invariants.

Example 24. Classical polarizations. Fix an orthonormal basis $x^1, \ldots, x^n$ of $V^*$, and obtain from it an orthonormal basis

$$\{x^a_i | i = 1, \ldots, k, a = 1, \ldots, n\}$$

for $(V^k)^*$. Then, for any $1 \leq i, j \leq k$, the classical polarization differential operator $P_{ij}$ on $\mathbb{R}[V^k]$, defined by

$$P_{ij} = \sum_{a=1}^{n} x^a_i \frac{\partial}{\partial x^a_j},$$

preserves $A^{(k)}$. Indeed, for any $H = H(x_1, \ldots, x_k) \in A^{(k)}$, which we may assume to be (multi-)homogeneous, we have

$$\langle \nabla f_{ij}, \nabla H \rangle_{V^k} = P_{ij}H + P_{ji}H \in A^{(k)}$$

because $A^{(k)}$ is Laplacian. Since $P_{ij}H$ and $P_{ji}H$ are homogeneous of different multi-degrees (unless $i = j$, in which case they are equal), and $A^{(k)}$ is multi-graded, they both belong to $A^{(k)}$.

Given $f \in A$, homogeneous of degree $d$, define $F(x_1, \ldots, x_n) = f(x_1)$, which is in $A^{(k)}$ by definition. The polynomials obtained from such $F$ by repeated application of classical polarization operators are called classical polarizations, and the algebra $\text{pol}(A, k) \subset A^{(k)}$ generated by all classical polarizations of all $f \in A$ is called the algebra of classical polarizations. Note that since the classical polarization operators are of order one, they satisfy the Leibniz rule, and so we would obtain the same algebra $\text{pol}(A, k)$ if we only let $f$ run through a set of generators of $A$. Moreover, $\text{pol}(A, k)$ equals the smallest sub-algebra of $\mathbb{R}[V]$ that contains all polynomials $F$ of the form above, and is preserved by the polarization operators.

In particular, note that $(P_{ij})^d F(x_1, \ldots, x_k) = df_i(x_1)$ is a classical polarization. Thus, the restriction $A^{(k)}|_{V_1}$ of $A^{(k)}$ to each invariant subspace $V_i \subset V^k$ contains a copy of $A$. If $\mathcal{F}$ is homogeneous, then $A^{(k)}|_{V_1} = A$. In contrast, for inhomogeneous $\mathcal{F}$ and $k \geq 2$, the authors do not know of a single example where these two algebras coincide, see Subsection [5.4] below.

Example 25. Wallach’s polarizations [Wal93, Appendix 2]. Given $i, j$, and $f(x) \in A$ homogeneous, let $F(x_1, \ldots, x_k) = f(x_i)$, and define the Wallach polarization
operator, denoted $P^f_{ij}$, by

$$P^f_{ij} = \sum_{a=1}^{\nu} \frac{\partial F}{\partial x^a_i} \frac{\partial}{\partial x^a_j}.$$ 

Note that for $f = r^2/2$, one recovers the classical operator $P_{ij}$.

The operators $P^f_{ij}$ preserve $A^{(k)}$. Indeed, let $Q = P_{ij}(F) \in A^{(k)}$. Then, for any multi-homogeneous $H \in A^{(k)}$, we have

$$A^{(k)} \ni \langle \nabla Q, \nabla H \rangle_{V^k} = P^f_{ij}(H) + \sum_{a,b} x^a_i \frac{\partial^2 F}{\partial x^a_i \partial x^b_j} \frac{\partial H}{\partial x^b_j}.$$ 

If $i = j$, the two summands above coincide, while for $i \neq j$, they are homogeneous with different multi-degrees. In either case, $P^f_{ij}(H) \in A^{(k)}$.

In particular, if we put $H(x_1, \ldots, x_k) = h(x_j)$ for some $h \in A$, we obtain the generalized polarization $P^f_{ij}(H)$, given by

$$(x_1, \ldots, x_k) \mapsto \langle (\nabla f)(x_i), (\nabla h)(x_j) \rangle_{V}.$$ 

5.2. Homogeneity of generalized polarizations. The goal of this subsection is to show, under a certain technical condition, that the algebra $A^{(k)}$ of generalized polarizations is homogeneous in the sense that it is the algebra of invariants of a certain group action, see Theorem 29 below.

The technical condition alluded to above is the following:

**Definition 26** ($k$ normal spaces). Let $(V, F)$ be an infinitesimal manifold submetry. We say $F$ satisfies the $k$ normal spaces condition, abbreviated $k$-NS, if there exists a non-empty open subset $U \subset V^k$ such that, for all $(x_1, \ldots, x_k) \in U$, we have

$$\nu_{x_1}(L_{x_1}) + \cdots + \nu_{x_k}(L_{x_k}) = V,$$

where for any $x \in V$, $\nu_{x}(L_{x}) \subset V$ denotes the normal space to the $F$-leaf $L_{x}$ at $x$.

If $G \subset O(V)$ is a compact subgroup, we say $G$ satisfies $k$-NS if its orbit decomposition does.

**Remark 27.** The following are immediate consequences of the definition. If $F$ satisfies $k$-NS, then it also satisfies $l$-NS for all $l \geq k$. Denoting by $F^0$ the decomposition of $V$ into the connected components of the $F$-leaves, $F^0$ satisfies $k$-NS if and only if $F$ does. If $F < F'$ (coarser than) and $F$ satisfies $k$-NS, then so does $F'$.

Recall that the principal stratum of an infinitesimal manifold submetry $(V, F)$ is the subset $V_0 \subset V$ of all points $x \in V$ such that $\nu_x(L_x)$ is spanned by $\{ \nabla f(x) \mid f \in B(F) \}$. It is non-empty and Zariski-open, in particular it is dense in the Euclidean topology.

The next lemma implies that $k$-NS is equivalent to the condition that $k$ generic normal spaces span $V$, and will ensure that Theorem 16 may be applied in the proof of Theorem 29 below.

**Lemma 28.** Let $(V, F)$ be an infinitesimal manifold submetry satisfying the $k$-NS condition. Then the open subset $U$ in Definition 26 may be assumed to be dense, $F^{(k)}$-saturated, and contained in $(V_0)^k$, where $V_0$ denotes the principal stratum of $F$.
Proof. Let \( \rho_1, \ldots, \rho_r \in A \) be a generating set. Since \( \nabla f(x) \in \nu_x(L_x) \) for every \( x \in V \) and \( f \in A \), the set

\[
U' = \{(x_1, \ldots, x_k) \in (V_0)^k | \text{span}\{\nabla \rho_a(x_b) | 1 \leq a \leq r, 1 \leq b \leq k\} = V\}
\]
satisfies the condition in Definition 26. Moreover, it is the complement of a Zariski-closed set, defined by polynomial equations in the polynomials \( \langle (\nabla \rho_a)(x_i), (\nabla \rho_b)(x_j) \rangle_V \). Since these are generalized polarizations by Example 25 we conclude that \( U' \) is \( \mathcal{F}^{(k)} \)-saturated. Finally, \( U' \) contains \( U \cap (V_0)^k \). In particular, the Zariski-open set \( U' \) is non-empty, therefore dense. \( \square \)

The following is the main result in this section:

**Theorem 29** (Homogeneity of generalized polarizations). Let \((V, \mathcal{F})\) be an infinitesimal manifold submetry satisfying k-NS, with associated algebra of basic polynomials \( A = B(\mathcal{F}) \). Let \( O(\mathcal{F}) \) be the closed subgroup of \( O(V) \) consisting of all \( g \in O(V) \) that map each \( \mathcal{F} \)-leaf to itself, and consider the diagonal action of \( O(\mathcal{F}) \) on \( V^k \). Then \( A^{(k)} = \mathbb{R}[V^k]^{O(\mathcal{F})} \).

Proof. By definition of \( G = O(\mathcal{F}) \), we have \( A \subset \mathbb{R}[V]^G \), and so \( A^{(k)} \subset \mathbb{R}[V^k]^G \). With Theorem 10 in mind, in order to prove the equality \( A^{(k)} = \mathbb{R}[V^k]^G \), it suffices to show that \( A^{(k)} \) is a local separating set for the decomposition of \( V^k \) into the \( G \)-orbits, because \( A^{(k)} \) is Laplacian by definition.

Let \( U \subset V^k \) be an open subset as in Definition 26 which, by Lemma 28, we may assume to be \( \mathcal{F}^{(k)} \)-saturated and contained in \((V_0)^k\). We will show that \( A^{(k)} \) separates \( G \)-orbits contained in \( U \). Explicitly, given

\[
(x_1, \ldots, x_k), (y_1, \ldots, y_k) \in U,
\]
such that every generalized polarization \( H \in A^{(k)} \) takes the same value on them, that is, \( H(x_1, \ldots, x_k) = H(y_1, \ldots, y_k) \), we will construct an orthogonal transformation \( g \in O(V) \) such that \( g(x_i, \ldots, x_k) = (y_1, \ldots, y_k) \), and then prove that \( g \in G \).

Let \( \rho_1, \ldots, \rho_r \in A \) be a generating set. We may assume \( \rho_1 = r^2/2 \). Consider the following two \( kr \)-tuples of vectors in \( V \):

\[
(\nabla \rho_a(x_i))_{a,i}, \quad (\nabla \rho_a(y_i))_{a,i}
\]

The inner product of any two entries in the first tuple coincides with the inner product of the corresponding entries in the second tuple, because such inner products are generalized polarizations, see Example 25. By Weyl’s First Fundamental Theorem for the orthogonal group (see Example 17), there exists \( g \in O(V) \) such that \( g \nabla \rho_a(x_i) = \nabla \rho_a(y_i) \) for all \( a, i \). Since \( \rho_1 = r^2/2 \), this implies that \( gx_i = y_i \) for all \( i \). Incidentally, \( g \) is uniquely determined because \( \{\nabla \rho_a(x_i)\}_{a,i} \) span \( V \).

It remains to show that \( g \in G \), that is, that \( g \) takes each \( \mathcal{F} \)-leaf to itself. Let \( v \in V \) be arbitrary. We will show that \( x_1 + v \) and \( g(x_1 + v) = y_1 + gv \) belong to the same \( \mathcal{F} \)-leaf. By the k-NS assumption, there exist scalars \( \lambda_{ai} \) such that

\[
v = \sum_{a,i} \lambda_{ai} \nabla \rho_a(x_i).
\]

We will need the following Claim, which follows immediately from the definition of the Wallach polarization operators (see Example 25):

**Claim:** Let \( H \in A^{(k)} \) be an arbitrary generalized polarization. Consider the
function $\Omega: \mathbb{R} \times V^k \to \mathbb{R}$ given by
\[
\Omega(t, z_1, \ldots, z_k) = H \left( z_1 + t \sum_{a,i} \lambda_{ai} \nabla \rho_a(z_i), \ z_2, \ldots, z_k \right)
\]
Then
\[
\frac{\partial \Omega}{\partial t}(t, z_1, \ldots, z_k) = \tilde{H} \left( z_1 + t \sum_{a,i} \lambda_{ai} \nabla \rho_a(z_i), \ z_2, \ldots, z_k \right)
\]
where $\tilde{H} = \sum_{a,i} \lambda_{ai} \frac{\partial \rho_a}{\partial t}(H) \in A^{(k)}$. In particular, $\frac{\partial \Omega}{\partial t}|_{t=0} \in A^{(k)}$ for all $b$.

We apply the Claim above to the case where $H(z_1, \ldots, z_k) = h(z_1)$ for an arbitrary $h \in A$. It follows that the polynomials $t \mapsto h(x_1 + tv)$ and $t \mapsto h(g(x_1 + tv))$ are equal, because they have the same derivatives, of all orders, at $t = 0$. Since $h \in A$ is arbitrary, this shows that $x_1 + v$ and $g(x_1 + v)$ belong to the same orbit, and, since $v$ was arbitrary, we conclude that $g \in G$. \hfill $\Box$

We finish this subsection with a couple of open questions regarding the $k$-NS condition.

**Question 30.** When $k \geq 2$, can the hypothesis that $\mathcal{F}$ satisfy the $k$-NS condition be dropped from Theorem 29?

**Question 31.** Is the $k$-NS condition equivalent to $k \dim(V/\mathcal{F}) \geq \dim(V)$?

### 5.3. When generalized polarizations generate

Let $G \subset O(V)$ be a closed subgroup, with algebra of invariants $A = \mathbb{R}[V]^G$, $k$ a positive integer, and let $A^{(k)}$ be the algebra of generalized polarizations. As mentioned earlier, we have $A^{(k)} \subset \mathbb{R}[V^k]^G$. The objective of this subsection is to give sufficient conditions for equality to hold, and in particular to prove Theorem 32.

First observe that equality cannot hold in full generality, because generalized polarizations depend only on the algebra of invariants $A = \mathbb{R}[V]^G$, which in turn only depends on the $G$-orbits, and not on $G$ itself. On the other hand, for $k = \dim(V)$ (and hence for all $k \geq \dim(V)$), the group $G$ itself is a $G$-orbit, in particular it is determined by $\mathbb{R}[V^k]^G$. Indeed, $V^{\dim(V)}$ can be identified with $\text{End}(V)$, and $G$ is the $G$-orbit through $\text{Id} \in \text{End}(V)$. For a concrete example, compare Examples 17 and 18. The groups $O(n)$ and $SO(n)$ have the same orbits, hence have the same algebra of invariants and algebras of generalized polarizations. But the algebras $\mathbb{R}[V^k]^{O(n)}$ and $\mathbb{R}[V^k]^{SO(n)}$ are distinct when $k \geq n$.

Subgroups $G, G' \subset O(V)$ are called orbit-equivalent if they have the same orbits. The discussion above shows that, at least when $k$ is large, we can only expect $A^{(k)} = \mathbb{R}[V^k]^G$ if $G$ is maximal (with respect to inclusion) in its orbit-equivalence class.

**Theorem 32.** Let $G \subset O(V)$ be a closed subgroup, with algebra of invariants $A = \mathbb{R}[V]^G$. Assume that $G$ is maximal in its orbit-equivalence class, and that the decomposition of $V$ into $G$-orbits satisfies $k$-NS. Then $\mathbb{R}[V^k]^G = A^{(k)}$.

**Proof.** Being “maximal in its orbit-equivalence class” is just another way of saying that $G = O(\mathcal{F})$, where $\mathcal{F}$ is the decomposition of $V$ into $G$-orbits. Thus the result follows immediately from Theorem 29. \hfill $\Box$
Remark 33. Theorem 32 gives an alternative proof of Theorem 1, which avoids \cite[Theorem 3.4]{DKW08}, because $G$ finite implies both $k$-NS for all $k$, and maximality in its orbit-equivalence class (see \cite[Lemma 1]{Swa02}).

Proof of Theorem 2 \begin{enumerate}
\item By Theorem 32, it suffices to show $G$ has the $k$-NS property. By Remark 27, it suffices to take $G$ to be a maximal torus in $O(V)$, and show that $G$ has the 2-NS property. If $V$ is even-dimensional, we may identify $V$ with $\mathbb{C}^n$, and let $G = U(1)^n$ act on $V$ in the standard way. Then the normal spaces at a pair points near $(1, \ldots, 1)$ and $(\sqrt{-1}, \ldots, \sqrt{-1})$ span $V$, so $G$ has 2-NS. If $V$ is odd-dimensional, we have $V = \mathbb{C}^n \oplus \mathbb{R}$ with $G = U(1)^n$ acting only on the $\mathbb{C}^n$ factor. Again, the normal spaces at a pair points near $(1, \ldots, 1, 0)$ and $(\sqrt{-1}, \ldots, \sqrt{-1}, 0)$ span $V$, so $G$ has 2-NS.
\item This follows immediately from Theorem 32 because $k \geq \dim(V)$ implies $k$-NS. Indeed, the position vector $v$ is normal to the $G$-orbit through $v$, for any $v \in V$.
\end{enumerate}

Remark 34. If $G \subset O(V)$ is maximal in its orbit-equivalence class, the algebra $A = \mathbb{R}[V]^G$ determines $G$, hence it also determines $\mathbb{R}[V^k]^G$ for all $k$. As a corollary of Theorem 2, we obtain an explicit way to produce $G$ and $\mathbb{R}[V^k]^G$ out of $A = \mathbb{R}[V]^G$. Namely, out of $A$ one constructs $A^{(\dim(V))} \subset \mathbb{R}[V^{\dim(V)}]$, which equals $\mathbb{R}[V^{\dim(V)}]^G$ by Theorem 2, and therefore $\mathbb{R}[V^k]^G$ is the restriction of $A^{(\dim(V))}$ to the subspace $V^k \subset V^{\dim(V)}$. Moreover, identifying $V^{\dim(V)}$ with $\text{End}(V)$, the group $G \subset \text{End}(V)$ is the leaf of $\mathcal{L}(A^{(\dim(V))})$ containing the identity endomorphism.

Remark 35. Theorem 32 applies to many groups $G$. In contrast, $\mathbb{R}[V^k]^G$ being generated by classical polarizations is quite special. Schwarz \cite{Sch07} has classified the complex rational representations $V$ of simple reductive algebraic groups $G$ such that $\mathbb{C}[V^k]^G$ is generated by classical polarizations. In particular the irreducible ones are coregular, that is, $\mathbb{C}[V]^G$ is free, and the reducible ones are isomorphic to a direct sum of a certain number of copies of the standard action of $\text{SL}(n)$ on $\mathbb{C}^n$. It is also conjectured in \cite{Sch07} that if $G$ is a finite group and $\mathbb{C}[V^k]^G$ is generated by classical polarizations, then the action of $G$ on $V$ is generated by reflections.

Even if $G$ is generated by reflections, $\mathbb{C}[V^2]^G$ (and hence $\mathbb{C}[V^k]^G$ for $k \geq 3$) may fail to be generated by classical polarizations, for example when $G$ is the Weyl group of type $D_4$. As for Wallach polarizations, they are enough to generate $\mathbb{C}[V^2]^G$ for $G$ of type $D_n$ for all $n$, but not for $G$ of type $F_4$. See \cite[Appendix 2]{Wal93} and \cite{Hum97}.

5.4. Homogeneity of infinitesimal manifold submetries. Not all infinitesimal manifold submetries $(V, \mathcal{F})$ are homogeneous, that is, given by the orbit decomposition of some compact subgroup $G \subset O(V)$. Historically, the first inhomogeneous examples were isoparametric foliations constructed in \cite{OT75, OT76}, later generalized in \cite{FKM81}, and the octonionic Hopf fibration of $\mathbb{R}^{16}$. The latter is an example of a Clifford foliation, see Example 19. All these are examples of composed Clifford foliations, see \cite{Rad14}. In some sense “most” composed Clifford foliations are inhomogeneous \cite{GR16}, and, since this construction can be applied to any homogeneous foliation, one can reasonably argue that there are “at least as many” inhomogeneous manifold submetries as homogeneous ones.

There are many ways one can prove that a given manifold submetry $(V, \mathcal{F})$ is inhomogeneous. One method involves generalized polarizations. Recall from
Subsection 5.1 that the restriction of \( F^{(k)} \) to the invariant subspace \( V \times 0 \times \cdots \times 0 \subset V^k \) is finer than the original manifold submetry \( F \), and that they coincide if \( F \) is homogeneous. Thus, if one can find a number \( k \) and a generalized polarization in \( A^{(k)} \) whose restriction to \( V \times 0 \times \cdots \times 0 \) is not constant on some \( F \)-leaf, then \( F \) is inhomogeneous. The following result provides a converse to this method, under the technical \( k \)-NS assumption:

**Theorem 36.** Let \( (V,F) \) be an infinitesimal manifold submetry with algebra of basic polynomials \( A \), and \( k \geq 2 \). Assume \( (V,F) \) satisfies \( k \)-NS, and that the restriction of \( F^{(k)} \) to the saturated subspace \( V \times \{0\} \times \cdots \times \{0\} \) is isomorphic to \( F \). Then \( F \) is homogeneous.

**Proof.** By Theorem 29, \( F^{(k)} \) is given by the orbits of the diagonal action of \( O(F) \) on \( V^k \). In particular, its restriction to \( V \times \{0\} \times \cdots \times \{0\} \) is given by the orbits of \( O(F) \) acting on \( V \). Thus \( F \) is also given by these orbits, that is, \( F \) is homogeneous. \( \square \)

As a corollary, if the restriction of \( F^{(\dim(V))} \) to the saturated subspace \( V \times \{0\} \times \cdots \times \{0\} \) is isomorphic to \( F \), then \( F \) is homogeneous. Note also that the condition in Theorem 36 can be rephrased as an algebraic condition on \( A \), namely “the restriction of \( A^{(k)} \) to \( V \times \{0\} \times \cdots \times \{0\} \) is equal to \( A \)”.

**Remark 37.** In the notations of Remarks 14 and 21, let \( A \) be a Laplacian algebra generated by the homogeneous quadratic polynomials \( A_2 \), seen as a Jordan subalgebra \( A_2 \simeq J \subset \text{Sym}^2(R^n) \). Let \( U \subset \text{Mat}_{n\times n}(R) \) be the enveloping algebra of \( J \), that is, the span of all products of matrices in \( J \). Then it is not hard to see that, for all \( k \geq 2 \), the algebra \( A^{(k)} \) of generalized polarizations is the algebra generated by those quadratic polynomials in \( R[V^k]_2 \) whose Hessians have the form

\[
\begin{bmatrix}
C_{11} & C_{12} & \cdots & C_{1k} \\
C_{12}^T & C_{22} & \cdots & C_{2k} \\
\vdots & \vdots & \ddots & \vdots \\
C_{1k}^T & \cdots & \cdots & C_{kk}
\end{bmatrix}
\]

where \( C_{ij} \in U \) for all \( i, j \). In particular, the restriction of \( A^{(k)} \) to \( V \times \{0\} \times \cdots \times \{0\} \) is independent of \( k \), for \( k \geq 2 \). Thus Theorem 36 implies that \( A \) is homogeneous if and only if the restriction of \( A^{(2)} \) to \( V \times \{0\} \) is equal to \( A \) if and only if every symmetric matrix in \( U \) belongs to \( J \).

Since most Clifford foliations do not satisfy the 2-NS condition, Remark 37 makes one wonder:

**Question 38.** Does Theorem 36 hold without the \( k \)-NS condition?
