Poisoning from alcohol based hand sanitizer in a hospitalized patient

Madhavi Katikaneni, Hugo Villanueva

ABSTRACT

Introduction: Alcohol based hand sanitizers help to decrease infection rates in hospitals. They contain isopropanol (isopropyl alcohol) or ethanol (ethyl alcohol) in high concentrations, and are easily accessible to patients and staff in health care settings.

Case Report: A 31-year-old female with history of alcohol abuse, seizure disorder and depression presented with symptoms of alcohol intoxication. Initial laboratory results were normal except an ethanol level of 311 mg/dl. She was admitted to the detoxification unit for ethyl alcohol intoxication. It was noted by the staff that she was trying to drink from the wall mounted hand sanitizers and was also seen sucking on alcohol wipes intermittently. On the third day in the detoxification unit, she was found to have lethargy, disorientation, tachycardia, hypotension, and tachypnea. She was given intravenous fluids and intubated for airway protection and transferred to intensive care unit. Laboratory tests showed normal pH, negative anion gap, normal glucose, large serum ketone, measured serum osmolality 340 mOsm/kg, osmolal gap 53 mOsm/kg, ethanol 13 mg/dl. She was treated for supraventricular arrhythmia, aspiration pneumonia. She did not require hemodialysis as acute kidney injury was mild, and osmolal gap and ketones came down with supportive care. Subsequently, she was extubated and recovered completely.

Conclusion: Alcohol based hand sanitizers should be used carefully under surveillance in detoxification and psychiatric units. Poisoning due to isopropanol can be managed effectively if recognized early. Elevated osmolal gap, absence of acidosis, and positive ketones are important clues which help in diagnosing isopropanol poisoning.

INTRODUCTION

Hand hygiene with alcohol based hand sanitizers helps to decrease infection rates in hospitals [1]. They are wall mounted, and easily accessible in hospital setting. The rate of intentional ingestion of hand sanitizers has been on the rise from 2005 to 2009 as per NPDS (National poison data system) [2]. Chemically, alcohol pads and hand sanitizers contain 60 to 80% isopropanol or ethanol.
CASE REPORT

A 31-year-old female with history of alcohol abuse, seizure disorder and depression presented with ataxia, confusion, disorientation. Her medications were trazadone 50 mg orally every night, quetiapine 100 mg orally twice a day, hydroxyzine dose unknown. She follows with primary physician infrequently and has previous admissions for alcohol withdrawal seizures. On admission vitals were temperature 98.6 degrees Fahrenheit, blood pressure 132/84 mmHg, pulse rate 74 per minute, respiratory rate 14 per minute, and had an unremarkable physical exam. Laboratory results showed blood urea nitrogen (BUN) 14 mg/dL, serum creatinine (Scr) 0.7 mg/dL, serum bicarbonate (co2) 28 mEq/L, anion gap (AG) 14 mEq/L, negative ketone in urine and an ethanol level of 311 mg/dL. The patient was admitted to the detoxification unit for ethyl alcohol intoxication and was given oral lorazepam to prevent alcohol withdrawal symptoms. It was noted that she was trying to drink from the wall mounted hand sanitizers (CAL STAT PLUS containing 63% isopropyl alcohol as active ingredient), and sucking on alcohol wipes intermittently in spite of staff counseling.

On the third day in the detoxification unit she was noted to be disoriented and agitated. Vital signs showed temperature 98 degrees Fahrenheit, blood pressure 90/60 mm Hg, pulse rate 124/minute, respiratory rate 20 per minute, and oxygen saturation was 90% on room air. Physical examination showed right lung base crackles, and non-focal neurological examination. She became more and more lethargic and was intubated for airway protection along with administration of intravenous fluids. Laboratory values showed BUN 11 mg/dL, Scr 1.2 mg/dL, lactate 0.7 mmol/L, AG 10 mEq/L, CO2 28 mEq/L, pH 7.37, PaCO2 43 mmHg, PaO2 96 mmHg, serum acetate large, urine ketone 40 mg/dL, measured serum osmolality 340 mOsm/kg, calculated osmolality 287 mOsm/kg, osmolal gap 53 mOsm/kg, serum ethanol 13 mg/dL, lactate 0.7 mmol/L, serum glucose 115 mg/dL, CPK 495 U/L.

She was later transferred to the intensive care unit (ICU), where she was treated for supraventricular arrhythmia which responded to adenosine and was later started on diltiazem drip. She was also placed on lorazepam drip for sedation along with intravenous fluids and multivitamins. Later she developed aspiration arrhythmia which responded to adenosine and was transferred to the intensive care unit (ICU), where she was treated for supraventricular arrhythmia which responded to adenosine and was transferred to the intensive care unit (ICU), where she was treated for supraventricular arrhythmia which responded to adenosine. DISCUSSION

The half-life of isopropanol which is usually 2.5–6 hours may be prolonged if there is combined intoxication with ethyl alcohol, because ethyl alcohol has higher affinity to alcohol dehydrogenase. Effects of intoxication are due to isopropanol itself and include central nervous system depression, myocardial depression, arrhythmia, respiratory depression, and rhabdomyolysis [3]. Although our patient’s isopropanol levels were sent to the lab, they were not available on-time to manage the patient. Hence, our diagnosis was mostly based on history and osmolar gap of 53 mOsm/kg. Other diagnostic clues were absence of acidosis and anion gap, large ketonemia [4]. Using the fact, that accumulation of low molecular substances like alcohols, propylene glycol, and diethylene glycol will raise serum osmolarity above the calculated level, we can estimate the isopropanol alcohol level. The normal osmolar gap measured using freezing point depression method is 10 mOsm/kg to 20 mOsm/kg, and for every 10 mg/dL of isopropanol the change in osmolality is 1.66. Based on this the level of isopropanol alcohol in our patient, was estimated as 71.4 mg/dL to 56.4 mg/dL [5]. If the patient presents late, as isopropyl alcohol is already metabolized to acetone, osmolal gap can be normal. In that situation the only clue would be elevated acetone. Interference of acetone with Jaffe calorimetric assay leading to false elevation of creatinine can occur. For every 100 mg/dL of acetone estimated increase in serum creatinine is 1 mg/dL [6].

Unlike methanol and ethylene glycol which have toxic metabolites like formic acid and oxalic acid, isopropanol has acetone as end product. Acetone is relatively nontoxic and fomepizole which is an alcohol dehydrogenase inhibitor is not recommended [7].

Hemodialysis is needed for levels more than 400 mg/dL and if there is central nervous system depression or renal failure.

Intoxication with isopropanol from hand sanitizers happened while patient was hospitalized. Although there was no bad outcome, it is essential to recognize the problem and make changes in detoxification units. It is essential for the clinician to probe the possibility of intoxication from other kind of alcohols. Facility to check isopropanol levels is not available in all hospitals, and even if levels are sent results may not be immediately available to make clinical decisions. Checking the osmolar gap, acetone levels in blood and urine on admission and having high index of suspicion will help in early recognition of isopropanol poisoning. Some recommendations regarding the use of hand sanitizers in detoxification units include listing of the contents of hand sanitizers as isopropanol instead of isopropyl alcohol, because ethyl alcohol has higher affinity to alcohol dehydrogenase. Effects of intoxication are due to isopropanol itself and include central nervous system depression, myocardial depression, arrhythmia, respiratory depression, and rhabdomyolysis [3]. Although our patient’s isopropanol levels were sent to the lab, they were not available on-time to manage the patient. Hence, our diagnosis was mostly based on history and osmolar gap of 53 mOsm/kg. Other diagnostic clues were absence of acidosis and anion gap, large ketonemia [4]. Using the fact, that accumulation of low molecular substances like alcohols, propylene glycol, and diethylene glycol will raise serum osmolarity above the calculated level, we can estimate the isopropanol alcohol level. The normal osmolar gap measured using freezing point depression method is 10 mOsm/kg to 20 mOsm/kg, and for every 10 mg/dL of isopropanol the change in osmolality is 1.66. Based on this the level of isopropanol alcohol in our patient, was estimated as 71.4 mg/dL to 56.4 mg/dL [5]. If the patient presents late, as isopropyl alcohol is already metabolized to acetone, osmolal gap can be normal. In that situation the only clue would be elevated acetone. Interference of acetone with Jaffe calorimetric assay leading to false elevation of creatinine can occur. For every 100 mg/dL of acetone estimated increase in serum creatinine is 1 mg/dL [6].
CONCLUSION

Alcohol based hand sanitizers should be used carefully under surveillance in detoxification and psychiatric units. Poisoning due to isopropanol can be managed effectively if recognized early. Elevated osmolar gap, absence of acidosis, and positive ketones are important clues which help in diagnosing isopropanol poisoning.

Edorium Journals: An introduction

Edorium Journals Team

About Edorium Journals
Edorium Journals is a publisher of high-quality, open access, international scholarly journals covering subjects in basic sciences and clinical specialties and subspecialties.

Invitation for article submission
We sincerely invite you to submit your valuable research for publication to Edorium Journals.

But why should you publish with Edorium Journals?
In less than 10 words - we give you what no one does.

Vision of being the best
We have the vision of making our journals the best and the most authoritative journals in their respective specialties. We are working towards this goal every day of every week of every month of every year.

Exceptional services
We care for you, your work and your time. Our efficient, personalized and courteous services are a testimony to this.

Editorial Review
All manuscripts submitted to Edorium Journals undergo pre-processing review, first editorial review, peer review, second editorial review and finally third editorial review.

Peer Review
All manuscripts submitted to Edorium Journals undergo anonymous, double-blind, external peer review.

Early View version
Early View version of your manuscript will be published in the journal within 72 hours of final acceptance.

Manuscript status
From submission to publication of your article you will get regular updates (minimum six times) about status of your manuscripts directly in your email.

Our Commitment

Six weeks
You will get first decision on your manuscript within six weeks (42 days) of submission. If we fail to honor this by even one day, we will publish your manuscript free of charge.

Four weeks
After we receive page proofs, your manuscript will be published in the journal within four weeks (31 days). If we fail to honor this by even one day, we will publish your manuscript free of charge and refund you the full article publication charges you paid for your manuscript.

Most Favored Author program
Join this program and publish any number of articles free of charge for one to five years.

Favored Author program
One email is all it takes to become our favored author. You will not only get fee waivers but also get information and insights about scholarly publishing.

Institutional Membership program
Join our Institutional Memberships program and help scholars from your institute make their research accessible to all and save thousands of dollars in fees make their research accessible to all.

Our presence
We have some of the best designed publication formats. Our websites are very user friendly and enable you to do your work very easily with no hassle.

Something more...
We request you to have a look at our website to know more about us and our services.

We welcome you to interact with us, share with us, join us and of course publish with us.
