L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
MINIMIZING FRACTIONAL HARMONIC MAPS
ON THE REAL LINE IN THE SUPERCRITICAL REGIME

VINCENT MILLOT, YANNICK SIRE, AND HUI YU

ABSTRACT. This article addresses the regularity issue for minimizing fractional
harmonic maps of order $s \in (0, 1/2)$ from an interval into a smooth manifold.
Hölder continuity away from a locally finite set is established for a general target.
If the target is the standard sphere, then Hölder continuity holds everywhere.

1. Introduction

In a series of recent articles [6, 7], F. Da Lio and T. Riviére introduced the concept
of 1/2-harmonic maps into a manifold. Given a compact smooth submanifold $\mathcal{N} \subset \mathbb{R}^d$
without boundary, such a map $u : \mathbb{R} \to \mathcal{N}$ is defined as a critical point of the nonlocal
energy
\[ E_s(u) := \frac{1}{2\pi} \int_{\mathbb{R}^2} \frac{|u(x) - u(y)|^2}{|x - y|^{2s}} \, dx dy. \]
It satisfies the Euler-Lagrange equation
\[ (-\Delta)^{\frac{s}{2}} u \perp \text{Tan}(u, \mathcal{N}), \]
where $(-\Delta)^{\frac{s}{2}}$ is the fractional Laplacian as defined in Fourier space. Obviously, this
equation is in strong analogy with the standard harmonic map equation into $\mathcal{N}$,
and one main issue is to prove a priori regularity. This was achieved in [6, 7], thus
extending the famous regularity result of F. Hélein for classical harmonic maps on
surfaces [11]. The notion of 1/2-harmonic maps has been then extended in [14, 16] to
higher dimensions, and partial regularity for minimizing or stationary 1/2-harmonic
maps established (in analogy with the classical harmonic map problem [1, 5, 17]).

All these works pave the way to a more general theory for fractional harmonic
maps where the energy $E_s$ is replaced by the Dirichlet form induced by the fractional
Laplacian $(-\Delta)^s$ with exponent $s \in (0, 1)$. As noticed in [15, Remark 1.7], the
case $s \in (0, 1/2)$ is in strong relation with the so-called nonlocal minimal surfaces
introduced by L. Caffarelli, J.M. Roquejoffre, and O. Savin [2]. For this reason, we
focus here on the case $s \in (0, 1/2)$, and as first step toward such a theory, we shall
consider minimizing $s$-harmonic maps in one space dimension. Before going further,
let us give some details on the mathematical framework.

Given $s \in (0, 1/2)$ and a bounded open interval $\omega \subset \mathbb{R}$, the nonlocal (or fractional)
$s$-energy in $\omega$ of a measurable function $u : \mathbb{R} \to \mathbb{R}^d$ is defined as
\[ E_s(u, \omega) := \frac{\gamma_s}{2} \int_{\omega \times \omega} \frac{|u(x) - u(y)|^2}{|x - y|^{1+2s}} \, dx dy + \gamma_s \int_{\omega \times (\mathbb{R}\setminus\omega)} \frac{|u(x) - u(y)|^2}{|x - y|^{1+2s}} \, dx dy. \]
The normalization constant $\gamma_s := 4\pi^{2s} \frac{\Gamma(1+2s)}{\Gamma(1-s)}$ is chosen in such a way that
\[ E_s(u, \omega) = \frac{1}{2} \int_{\mathbb{R}} |(-\Delta)^{\frac{s}{2}} u|^2 \, dx \quad \forall u \in C^0_0(\omega; \mathbb{R}^d). \]
Following [15, Section 2], we denote by $\dot{H}^s(\omega; \mathbb{R}^d)$ the Hilbert space made of $L^2_{\text{loc}}(\mathbb{R})$
functions $u$ such that $E_s(u, \omega) < \infty$, and we set
\[ \dot{H}^s(\omega; \mathcal{N}) := \{ u \in \dot{H}^s(\omega; \mathbb{R}^d) : u(x) \in \mathcal{N} \text{ a.e. on } \mathbb{R} \}. \]

Definition. We say that $u \in \dot{H}^s(\omega; \mathcal{N})$ is a minimizing $s$-harmonic map in $\omega$ if
\[ E_s(u, \omega) \leq E_s(\tilde{u}, \omega) \]
for every $\tilde{u} \in \tilde{H}^s(\omega; N)$ such that $\text{spt}(\tilde{u} - u) \subseteq \omega$.

Exactly as in the case $s = 1/2$ (see [14, Remark 4.24]), a minimizing $s$-harmonic map satisfies the Euler-Lagrange equation

$$(\nabla)^s u \perp \text{Tan}(u, N) \text{ in } \mathcal{D}'(\omega).$$

In terms of scaling, this equation turns out to be supercritical (since $s \in (0, 1/2)$), and one may expect that minimizing $s$-harmonic maps are singular, exactly as it happens for (classical) minimizing harmonic maps in dimensions greater than three [17].

The main objective of this paper is to provide a first partial regularity result for minimizing $s$-harmonic maps. At this stage, we should point out that existence is not an issue. Indeed, prescribing an exterior condition $g \in \tilde{H}^s(\omega; N)$, one can minimize the energy $\mathcal{E}_s(\cdot, \omega)$ over all maps $u \in \tilde{H}^s(\omega; N)$ satisfying $u = g$ a.e. in $\mathbb{R} \setminus \omega$. Existence for this minimization problem easily follows from the Direct Method of Calculus of Variations, and it obviously produces a minimizing $s$-harmonic map in $\omega$.

Our first main result concerns the case of a general (smooth) target $N$.

**Theorem 1.1.** For $s \in (0, 1/2)$, let $u \in \tilde{H}^s(\omega; N)$ be a minimizing $s$-harmonic map in $\omega$. Then $u$ is locally Hölder continuous in $\omega$ away from a locally finite set of points.

The proof of Theorem 1.1 follows somehow the general scheme for proving partial regularity of minimizing harmonic maps, or more precisely of minimizing harmonic maps with (partially) free boundary. Indeed, the problem can be rephrased as a degenerate regularity problem for harmonic maps with free boundary, once we use the so-called Caffarelli-Silvestre extension [3]. With this respect, our arguments resemble to the ones in [4, 9, 10], except that they have to be suitably modified to deal with our degenerate setting. In view of this classical literature, one may wonder if Hölder continuity implies higher order regularity. We do not address this question here, as it will be the object of a future work. In a complementary direction, one can ask whether or not a (one dimensional) minimizing $s$-harmonic can be singular. We believe that, in general, Theorem 1.1 is optimal, but the question remains open. However, if the manifold $N$ is a standard sphere, then there are no singularities at all. This statement (and proof) is in a sense an amusing fractional counterpart of the regularity result of R. Schoen & K. Uhlenbeck [18] for minimizing harmonic maps into spheres.

**Theorem 1.2.** For $s \in (0, 1/2)$, let $u \in \tilde{H}^s(\omega; \mathbb{S}^{d-1})$ be a minimizing $s$-harmonic map in $\omega$. Then $u$ is locally Hölder continuous in $\omega$.

This article is organized as follows. In Section 2, we introduce the notion of harmonic maps with free boundary induced by the Caffarelli-Silvestre extension, together with some fundamental properties such as the monotonicity formula. In Section 3, we prove an $\varepsilon$-regularity theorem for those harmonic maps with free boundary. Section 4 is devoted to compactness properties of minimizing $s$-harmonic maps, and Theorems 1.1 & 1.2 are proved in Section 5.

**Notation.** We shall often identify $\mathbb{R}$ with $\partial \mathbb{R}^2_+ = \mathbb{R} \times \{0\}$. More generally, a set $A \subseteq \mathbb{R}$ can be identified with $A \times \{0\} \subseteq \partial \mathbb{R}^2_+$. Points in $\mathbb{R}^2$ are written $x = (x, y)$. We denote by $B_r(x)$ the open disc in $\mathbb{R}^2$ of radius $r$ centered at $x = (x, y)$. For an arbitrary set $\Omega \subseteq \mathbb{R}^2$, we write $\Omega^+ := \Omega \cap \mathbb{R}^2_+$ and $\partial^+ \Omega := \partial \Omega \cap \mathbb{R}^2_+$. If $\Omega \subseteq \mathbb{R}^2_+$ is a bounded open set, we shall say that $\Omega$ is admissible whenever

- $\partial \Omega$ is Lipschitz regular;
- the (relative) open set $\partial^0 \Omega \subseteq \partial \mathbb{R}^2_+ \simeq \mathbb{R}$ is defined by

  $$\partial^0 \Omega := \left\{ x \in \partial \Omega \cap \partial \mathbb{R}^2_+ : B_{\frac{r}{2}}(x) \subseteq \Omega \text{ for some } r > 0 \right\},$$

  is non empty and has Lipschitz boundary;
- $\partial \Omega = \partial^+ \Omega \cup \partial^0 \Omega$. 

Finally, we denote by $d_{\mathcal{N}}$ the distance function on $\mathbb{R}^d$ to the manifold $\mathcal{N}$, i.e.,

$$d_{\mathcal{N}}(z) := \inf_{p \in \mathcal{N}} |z - p|.$$ 

The tangent and normal spaces to $\mathcal{N}$ at a point $p \in \mathcal{N}$ are denoted by $\text{Tan}(p, \mathcal{N})$ and $\text{Nor}(p, \mathcal{N})$, respectively.

2. Minimizing weighted harmonic maps with free boundary

The proof of our results relies on the already mentioned Caffarelli-Silvestre extension procedure [3] which allows to rephrase our fractional problem into a local one. Before going into details on the extension of minimizing $s$-harmonic maps, we briefly introduce the resulting local problem and its functional setting.

2.1. Minimizing weighted harmonic maps. For a bounded admissible open subset $\Omega \subseteq \mathbb{R}^2_+$, we consider the weighted spaces

$$L^2(\Omega; \mathbb{R}^d, y^a dx) := \left\{ v \in L^1_{\text{loc}}(\Omega; \mathbb{R}^d) : y^{\frac{a}{2}}|v| \in L^2(\Omega) \right\} \quad \text{with } a := 1 - 2s > 0,$$

and

$$H^1(\Omega; \mathbb{R}^d, y^a dx) := \left\{ v \in L^2(\Omega, y^a dx) : \nabla v \in L^2(\Omega, y^a dx) \right\}.$$ 

We refer to [15, Section 2] for the main properties of these spaces that we shall use. We simply recall that a map $v \in H^1(\Omega; \mathbb{R}^d, y^a dx)$ has a well defined trace on $\partial_0 \Omega$, and the trace operator from $H^1(\Omega; \mathbb{R}^d, y^a dx)$ into $L^2(\partial_0 \Omega; \mathbb{R}^d)$ is a compact linear operator.

On $H^1(\Omega, y^a dx dy)$, we define the weighted Dirichlet energy

$$E_s(v, \Omega) := \frac{1}{2} \int_{\Omega} y^a |\nabla v|^2 \, dx.$$ 

**Definition 2.1.** Let $\Omega \subseteq \mathbb{R}^2_+$ be a bounded admissible open set, and consider a map $v \in H^1(\Omega; \mathbb{R}^d, y^a dx)$ such that $v(x) \in \mathcal{N}$ a.e. on $\partial^0 \Omega$. We say that $v$ is a minimizing weighted harmonic map in $\Omega$ with respect to the (partially) free boundary $v(\partial^0 \Omega) \subseteq \mathcal{N}$ if

$$E_s(v, \Omega) \leq E_s(w, \Omega)$$

for every competitor $w \in H^1(\Omega, y^a dx)$ satisfying $w(x) \in \mathcal{N}$ a.e. on $\partial^0 \Omega$, and such that $\text{spt}(w - v) \subseteq \Omega \cup \partial^0 \Omega$. In short, we shall say $v$ is a minimizing weighted harmonic map with free boundary in $\Omega$.

**Remark 2.2.** Using variations supported in $\Omega$, one obtains that a minimizing weighted harmonic map $v$ with free boundary in $\Omega$ satisfies

$$\text{div}(y^a \nabla v) = 0 \quad \text{in } \Omega. \quad (2.1)$$

In particular, $v \in C^\infty(\Omega)$ by standard elliptic theory. The regularity issue is then at (and only at) the free boundary $\partial^0 \Omega$. Arguing exactly as [4, Section 2], one obtains

$$y^a \partial_y v \perp \text{Tan}(v, \mathcal{N}) \quad \text{on } \partial^0 \Omega$$

in the duality sense. In other words, the (full) Euler-Lagrange equation derived from minimality is

$$\int_{\Omega} y^a \nabla v \cdot \nabla \zeta \, dx = 0 \quad (2.2)$$

for every $\zeta \in H^1(\Omega; \mathbb{R}^d, y^a dx)$ satisfying $\zeta(x) \in \text{Tan}(v(x), \mathcal{N})$ for a.e. $x \in \partial^0 \Omega$, and such that $\text{spt}(\zeta) \subseteq \Omega \cup \partial^0 \Omega$. 

2.2. Extending minimizing s-harmonic maps. We now move on the extension procedure of [3]. Given a bounded open interval $\omega \subseteq \mathbb{R}$, we define the extension $u^\omega : \mathbb{R}^d_+ \to \mathbb{R}^d$ of a map $u \in \hat{H}^s(\omega; \mathbb{R}^d)$ by

$$u^\omega(x, y) := \sigma_s \int_{\mathbb{R}} \frac{t^{2s} u(t)}{(x-y)^2 + t^2} \frac{dt}{t^s} \quad \text{with} \quad \sigma_s := \pi^{-\frac{d}{2}} \frac{\Gamma(\frac{1+2s}{2})}{\Gamma(s)}.$$  

This extension can be referred to as fractional harmonic extension of $u$ (by analogy with the case $s = 1/2$) as it solves

$$\begin{cases} 
\text{div}(y^s \nabla u^\omega) = 0 & \text{in } \mathbb{R}^d_+, \\
u^\omega = u & \text{on } \mathbb{R} \simeq \partial \mathbb{R}^2_+.
\end{cases}$$  

(2.3)

It turns out that $u^\omega \in H^1(\Omega; \mathbb{R}^d, y^s dx)$ for every bounded admissible open set $\Omega \subseteq \mathbb{R}^2_+$ such that $\partial \Omega \subseteq \omega$. In addition, $u^\omega \in L^\infty(\mathbb{R}^2_+)$ whenever $u \in L^\infty(\mathbb{R})$, and $\|u^\omega\|_{L^\infty(\mathbb{R}^2_+)} \leq \|u\|_{L^\infty(\mathbb{R})}$. We refer to [15, Section 2] for further details.

We shall make use of the following converse statement to control the fractional energy by the weighted Dirichlet energy.

**Lemma 2.3.** Let $r > 0$ and $v \in H^1(B_{2r}^+, \mathbb{R}^d, y^s dx)$. The trace of $v$ on the interval $\omega_r := \partial^0 B_{2r}^+$ belongs to $H^s(\omega_r; \mathbb{R}^d)$, and

$$\int_{\omega_r \times \omega_r} \frac{|v(x) - v(y)|^2}{|x-y|^{1+2s}} \, dx \, dy \leq C \mathcal{E}_s(v, B_{2r}^+).$$

for some constant $C = C(s)$.

**Proof.** Without loss of generality, we may assume that $v$ has a vanishing average over the half ball $B_{2r}^+$.

Let $\zeta \in C^\infty(B_{3r}; [0, 1])$ be a cut-off function such that $\zeta(x) = 1$ for $|x| \lesssim r$, $\zeta(x) = 0$ for $|x| \gtrsim 3r/2$, and satisfying $|\nabla \zeta| \lesssim C/r$. The function $v_r := \zeta v$ belongs to $H^1(\mathbb{R}^2_+; \mathbb{R}^d, y^s dx)$, and Poincaré’s inequality in $H^1(\mathbb{R}^2_+; \mathbb{R}^d, y^s dx)$ (see e.g. [8]) yields

$$\int_{\mathbb{R}^2_+} y^s |\nabla v_r|^2 \, dx \leq 2\mathcal{E}_s(v, B_{2r}^+) + \frac{C}{r^2} \int_{B_{3r}^+} y^s |v|^2 \, dx \leq C_s \mathcal{E}_s(v, B_{2r}^+).$$  

(2.4)

On the other hand, it follows from [3] (see also [15, Lemma 2.8]) that

$$\int_{\omega_r \times \omega_r} \frac{|v(x) - v(y)|^2}{|x-y|^{1+2s}} \, dx \, dy \leq \int_{\mathbb{R} \times \mathbb{R}^d} \frac{|v_r(x) - v_r(y)|^2}{|x-y|^{1+2s}} \, dx \, dy \leq C_s \int_{\mathbb{R}^2_+} y^s |\nabla v_r|^2 \, dx,$$  

(2.5)

for some constant $C_s$ depending only on $s$. Gathering (2.4) and (2.5) leads to the announced estimate. \hfill \square

The following proposition draws links between minimizing $s$-harmonic maps and minimizing weighted harmonic maps with free boundary. Its proof follows exactly as in [14, Proposition 4.9] (see also [15, Corollary 2.13]), and we shall omit it.

**Proposition 2.4.** Let $\omega \subseteq \mathbb{R}$ be a bounded open interval, and $u \in \hat{H}^s(\omega; N)$ a minimizing $s$-harmonic map in $\omega$. Then $u^\omega$ is a minimizing weighted harmonic map in $\Omega \subseteq \mathbb{R}^2_+$ satisfying $\partial^0 \Omega \subseteq \omega$.

2.3. The monotonicity formula. In this subsection, we consider a bounded admissible open set $\Omega \subseteq \mathbb{R}^2_+$, and a minimizing weighted harmonic map $v \in H^1(\Omega; \mathbb{R}^d, y^s dx)$ with free boundary. We present the fundamental monotonicity formula involving the following density function: for a point $x_0 = (x_0, 0) \in \partial^0 \Omega$ and $r > 0$ such that $B_r^+(x_0) \subseteq \Omega$, we set

$$\Theta_r(x_0, r) := \frac{1}{r^{1-2s}} \mathcal{E}_s(v, B_r^+(x_0)).$$
Lemma 2.5. For every $x_0 \in \partial^0 \Omega$ and $r > \rho > 0$ such that $B^+_\rho(x_0) \subseteq \Omega$,

$$\Theta_v(x_0, r) = \Theta_v(x_0, \rho) = \int_{B^+_\rho(x_0) \setminus B^+_\rho(x_0)} y^a \frac{|(x - x_0) \cdot \nabla v|^2}{|x - x_0|^{3-2a}} \, dx.$$  

Proof. The proof follows classically from the stationarity implied by minimality. To be more precise, let us consider a vector field $X = (X_1, X_2) \in C^1(\mathbb{R}^2; \mathbb{R}^2)$ compactly supported in $\Omega \cup \partial^0 \Omega$ and such that $X_2 = 0$ on $\mathbb{R} \times \{0\}$. Then consider a compactly supported $C^1$-extension of $X$ to the whole $\mathbb{R}^2$, still denoted by $X$. We define $\{\phi_t\}_{t \in \mathbb{R}}$ the flow on $\mathbb{R}^2$ generated by $X$, i.e., for $x \in \mathbb{R}^2$, the map $t \mapsto \phi_t(x)$ is defined as the unique solution of the differential equation

$$\begin{cases}
\frac{d}{dt} \phi_t(x) = X(\phi_t(x)), \\
\phi_0(x) = x.
\end{cases}$$

Notice that $\phi_t(\Omega) = \Omega$, $\phi_t(\partial^0 \Omega) = \partial^0 \Omega$, and $\text{spt}(\phi_t - \text{id}_{\mathbb{R}^2}) \cap \mathbb{R}^2 \subseteq \Omega \cup \partial^0 \Omega$. As a consequence, the map $v_t := v \circ \phi_t \in H^1(\Omega; \mathbb{R}^d, g^a \, dx)$ satisfies $v_t(x) \in \mathcal{N}$ a.e. on $\partial^0 \Omega$, and $\text{spt}(v_t - v) \subseteq \Omega \cup \partial^0 \Omega$. By minimality $E_a(v, \Omega) \leq E_a(v_t)$ for every $t \in \mathbb{R}$, so that

$$\left\{ \frac{d}{dt} E_a(v_t, \Omega) \right\}_{t=0} = 0.$$  

Computing this derivative (see e.g. [19, Chapter 2.2] or [15]) leads to

$$\int_\Omega y^a \left( |\nabla v|^2 \text{div} X - 2 \sum_{i,j=1}^2 (\partial_i v \cdot \partial_j v) \partial_j X_i \right) \, dx + a \int_\Omega y^{a-1} |\nabla v|^2 X_2 \, dx = 0 \quad (2.6)$$

for every vector field $X = (X_1, X_2) \in C^1(\mathbb{R}^2; \mathbb{R}^2)$ compactly supported in $\Omega \cup \partial^0 \Omega$ and such that $X_2 = 0$ on $\mathbb{R} \times \{0\}$. From equation (2.6), the announced monotonicity follows as in [15, Lemma 6.2].

Corollary 2.6. For every $x_0 \in \partial^0 \Omega$, the limit

$$\Theta_v(x_0) := \lim_{r \downarrow 0} \Theta_v(x_0, r)$$

exists, and the function $\Theta_v : \partial^0 \Omega \to [0, \infty)$ is upper semicontinuous. In addition,

$$\Theta_v(x_0, r) - \Theta_v(x_0) = \int_{B^+_\rho(x_0)} y^a \frac{|(x - x_0) \cdot \nabla v|^2}{|x - x_0|^{3-2a}} \, dx. \quad (2.7)$$

Proof. The existence of the limit defining $\Theta_v$ as well as (2.7) are straightforward consequences of Lemma 2.5. Then $\Theta_v$ is upper semicontinuous as a pointwise limit of a decreasing family of continuous functions.

3. The $\varepsilon$-regularity theorem

3.1. An extension lemma and the hybrid inequality. This subsection is essentially devoted to the construction of comparison maps. We shall start with the construction of competitors from a boundary data satisfying a small oscillation condition. Testing minimality against such competitors leads to the so-called hybrid inequality (see [9, 10]), a central estimate in the proof of the $\varepsilon$-regularity theorem.

Let us start with an elementary lemma.

Lemma 3.1. Let $v \in H^1(\partial^+ B_1; \mathbb{R}^d, g^a \, dx)$ be such that $v(\pm 1, 0) \in \mathcal{N}$. Then,

$$d_{\mathcal{H}}^a(v(x)) \leq \left( \int_{\partial^+ B_1} y^a |\partial_r v|^2 \, d\mathcal{H}^1 \right)^{1/2} \left( \int_{\partial^+ B_1} y^{-a} d_H^a(v) \, d\mathcal{H}^1 \right)^{1/2}$$

for every $x \in \partial^+ B_1$. 

Proof. First recall that $H^1(\partial^+ B_1; \mathbb{R}^d, y^a dx) \hookrightarrow W^{1,1}(\partial^+ B_1; \mathbb{R}^d)$, so that maps in $H^1(\partial^+ B_1; \mathbb{R}^d, y^a dx)$ are continuous on $\partial^+ B_1$. Then notice that the function $d_N$ is 1-Lipschitz, and by chain rule one derives $|\nabla d_N^2| \leq 2d_N$ a.e. in $\mathbb{R}^d$. In turns, it implies that $d_N^2(u) \in H^1(\partial^+ B_1, y^a dx)$ and

$$|\partial_v d_N^2(v)| \leq 2d_N(v)|\partial_v v| \quad \text{a.e. on } \partial^+ B_1.$$ 

Since $\forall (1,0) \in \mathcal{N}$, this estimate implies that for every $x \in \partial^+ B_1$,

$$d_N^2(v(x)) \leq 2 \int_{(1,0),x} d_N(v)|\partial_v v| d\mathcal{H}^1,$$

where $((1,0),x)$ denotes the arc in $\partial^+ B_1$ going from $(1,0)$ to $x$. The announced inequality then follows from Cauchy-Schwarz inequality. \hfill \square

Lemma 3.2 (Comparison maps). There exist two constants $\varepsilon_0 = \varepsilon_0(\mathcal{N}) > 0$ and $C = C(\mathcal{N}, s)$ such that the following holds. Let $v \in H^1(\partial^+ B_1; \mathbb{R}^d, y^a dx)$ be such that $v(\pm 1,0) \in \mathcal{N}$, and $\xi \in \mathbb{R}^d$. If

$$\left(\int_{\partial^+ B_1} y^a|\partial_v v|^2 d\mathcal{H}^1\right) \left(\int_{\partial^+ B_1} y^{-a}|v - \xi|^2 d\mathcal{H}^1 + \int_{\partial^+ B_1} y^{-a} d_N^2(v) d\mathcal{H}^1\right) \leq \varepsilon_0,$$ (3.1)

then there exists $w \in H^1(B_1^+; \mathbb{R}^d, y^a dx)$ such that $w(\partial^0 B_1^+) \subseteq \mathcal{N}$, $w = v$ on $\partial^+ B_1$, and

$$\int_{B_1} y^a|\nabla w|^2 dx \leq C \left(\int_{\partial^+ B_1} y^a|\partial_v v|^2 d\mathcal{H}^1\right)^{1/2} \left(\int_{\partial^+ B_1} y^{-a}|v - \xi|^2 d\mathcal{H}^1 + \int_{\partial^+ B_1} y^{-a} d_N^2(v) d\mathcal{H}^1\right)^{1/2}.$$ (3.2)

Proof. Reflect $v$ evenly to the entire sphere $\partial B_1$. Obviously, $v \in H^1(\partial B_1; \mathbb{R}^d, |y|^a dx)$ by symmetry. We consider the variational solution $h \in H^1(B_1^+; \mathbb{R}^d, |y|^a dx)$ of

$$\begin{cases}
\text{div}(|y|^a \nabla h) = 0 & \text{in } B_1,

h = v & \text{on } \partial B_1.
\end{cases}$$ (3.3)

Note that $h \in L^\infty(B_1)$. Indeed, since $v$ is absolutely continuous, it is bounded. Since $h$ minimizes $E_h(\cdot, B_1)$ over all maps equal to $v$ on $\partial B_1$, a classical truncation argument shows that $|h|$ does not exceed $||v||_{L^\infty(\partial B_1)}$.

Next, recalling [3, Lemma 6.2], we have

$$\int_{\partial B_1} |y|^a|\partial_v h|^2 d\mathcal{H}^1 \leq \int_{\partial B_1} |y|^a|\partial_v v|^2 d\mathcal{H}^1.$$ (3.4)

Using (3.2) and (3.3), we infer from the divergence theorem and Cauchy-Schwarz inequality that

$$\int_{B_1} |y|^a|\nabla h|^2 dx = \int_{B_1} |y|^a|\nabla (h - \xi)|^2 dx$$

$$= \int_{\partial B_1} |y|^a(h - \xi) \cdot \partial_n h d\mathcal{H}^1$$

$$\leq \left(\int_{\partial B_1} |y|^a|v - \xi|^2 d\mathcal{H}^1\right)^{1/2} \left(\int_{\partial B_1} |y|^a|\partial_v v|^2 d\mathcal{H}^1\right)^{1/2}.$$ (3.5)

Hence, by symmetry,

$$\int_{B_1} |y|^a|\nabla h|^2 dx \leq 2 \left(\int_{\partial B_1} y^a|v - \xi|^2 d\mathcal{H}^1\right)^{1/2} \left(\int_{\partial B_1} y^a|\partial_v v|^2 d\mathcal{H}^1\right)^{1/2}. \quad (3.4)$$
By the fundamental theorem of calculus (and symmetry), we have
\[ |v(x) - v(x_0)|^2 \leq 2 \int_{(x_0, x_1)} |v - v(x_0)||\partial_x v| \, d\mathcal{H}^1 \]
\[ \leq 2 \left( \int_{\partial^+ B_1} y^{-a}|v - v(x_0)|^2 \, d\mathcal{H}^1 \right)^{1/2} \left( \int_{\partial^+ B_1} y^a|\partial_x v|^2 \, d\mathcal{H}^1 \right)^{1/2} \]
for every \( x, x_0 \in \partial B_1 \).

We choose the point \( x_0 \) in such a way that \( x \mapsto |v(x) - \xi| \) achieves its minimum at \( x_0 \). Then,
\[ |v - v(x_0)|^2 \leq 2|v - \xi|^2 + 2|v(x_0) - \xi|^2 \leq 4|v - \xi|^2 \quad \text{on} \quad \partial B_1. \]
Consequently,
\[ |v(x) - v(x_0)|^2 \leq 4 \left( \int_{\partial^+ B_1} y^{-a}|v - \xi|^2 \, d\mathcal{H}^1 \right)^{1/2} \left( \int_{\partial^+ B_1} y^a|\partial_x v|^2 \, d\mathcal{H}^1 \right)^{1/2} \]
(3.5)
for every \( x \in \partial B_1 \).

Since \( h \) is bounded, \( |h - v(x_0)|^2 \) belongs to \( \mathcal{H}^1(B_1, |y|^a \, dx) \). Moreover,
\[ \text{div}(|y|^a \nabla (|h - v(x_0)|^2)) \geq 0 \quad \text{in} \quad B_1, \]
and the maximum principle in [8] together with (3.5) implies that
\[ |h(x) - v(x_0)|^2 \leq 4 \left( \int_{\partial^+ B_1} y^{-a}|v - \xi|^2 \, d\mathcal{H}^1 \right)^{1/2} \left( \int_{\partial^+ B_1} y^a|\partial_x v|^2 \, d\mathcal{H}^1 \right)^{1/2} \]
for every \( x \in B_1 \). Applying Lemma 3.1 at \( x = x_0 \), we now infer that
\[ d_N(h(x)) \leq |d_N(h(x)) - d_N(v(x_0))| + d_N(v(x_0)) \]
\[ \leq |h(x) - v(x_0)| + d_N(v(x_0)) \]
\[ \leq 2 \left( \int_{\partial^+ B_1} y^{-a}|v - \xi|^2 \, d\mathcal{H}^1 \right)^{1/4} \left( \int_{\partial^+ B_1} y^a|\partial_x v|^2 \, d\mathcal{H}^1 \right)^{1/4} \]
\[ + \left( \int_{\partial^+ B_1} y^{-a}d_N^2(v) \, d\mathcal{H}^1 \right)^{1/4} \left( \int_{\partial^+ B_1} y^a|\partial_x v|^2 \, d\mathcal{H}^1 \right)^{1/4} \]
\[ \leq 2 \left( \int_{\partial^+ B_1} y^a|\partial_x v|^2 \, d\mathcal{H}^1 \right)^{1/4} \left( \int_{\partial^+ B_1} y^{-a}|v - \xi|^2 \, d\mathcal{H}^1 \right)^{1/4} \]
\[ + \int_{\partial^+ B_1} y^{-a}d_N^2(v) \, d\mathcal{H}^1 \]
\[ \leq 2 \left( \int_{\partial^+ B_1} y^a|\partial_x v|^2 \, d\mathcal{H}^1 \right)^{1/4} \left( \int_{\partial^+ B_1} y^{-a}|v - \xi|^2 \, d\mathcal{H}^1 \right)^{1/4} \]
for every \( x \in B_1 \). By our assumption, we thus have
\[ d_N(h) \leq 2\varepsilon_0^{1/4} \quad \text{in} \quad B_1. \]
As a consequence, if \( \varepsilon_0 = \varepsilon_0(N) \) is small enough, \( h \) takes values in a small tubular neighborhood of \( \mathcal{N} \). In such a neighborhood, the nearest point retraction \( \pi_N \) on \( \mathcal{N} \) is well defined and smooth. Therefore, \( \pi_N(h) \) belongs to \( \mathcal{H}^1(B_1; \mathcal{N}, |y|^a \, dx) \), and
\[ \|\pi_N(h) - h\|_{L^\infty(B_1)} \leq 4 \left( \int_{\partial^+ B_1} y^a|\partial_x v|^2 \, d\mathcal{H}^1 \right)^{1/2} \left( \int_{\partial^+ B_1} y^{-a}|v - \xi|^2 \, d\mathcal{H}^1 \right)^{1/2} \]
\[ + \int_{\partial^+ B_1} y^{-a}d_N^2(v) \, d\mathcal{H}^1 \quad \text{. (3.6)} \]
We shall now construct the extension \( w \) interpolating \( h \) and \( \pi_N(h) \) near \( \partial^+ B_1 \). We proceed as follows. Consider the set
\[ A := \left\{ x = (x, y) \in \overline{B}_1^+: 0 \leq y \leq 1/2, \ |x| \leq \sqrt{1 - y^2} - y^2 \right\}, \]
and let ζ ∈ C∞(B₁⁺ ∩ [0, 1]) be a smooth cut-off function satisfying ζ = 1 in A ∩ B₁⁺, and ζ = 0 on ∂⁺B₁. From the very definition of A, we can even find ζ in such a way that
\[ |\partial_γ ζ(x, y)| \leq C \quad \text{and} \quad |\partial_λ ζ(x, y)| \leq Cy^{-2}, \tag{3.7} \]
where C = C(s). In particular, ζ ∈ H¹(B₁⁺ ∩ [0, 1], y^α dx). We finally define
\[ w := ζ(π_N(h) - h) + h \in H¹(B₁⁺; R^d, y^α dx). \]
By construction, w(x) ∈ N for x ∈ ∂⁺B₁⁺, and w = h = v on ∂⁺B₁. Then we estimate
\[
\int_{B₁⁺} y^α |\nabla w|^2 \, dx \leq 2 \int_{B₁⁺} y^α |\nabla h|^2 \, dx + 4 \int_{B₁⁺} y^α |\nabla (π_N(h) - h)|^2 \, dx \\
+ 4 \int_{B₁⁺} y^α |\nabla ζ|^2 |π_N(h) - h|^2 \, dx \\
\leq C \int_{B₁⁺} y^α |\nabla h|^2 \, dx + 4\|π_N(h) - h\|^2_{L^∞(B₁⁺)} \int_{B₁⁺} y^α |\nabla ζ|^2 \, dx. \tag{3.8}
\]
Gathering (3.8) with (3.4), (3.6), and (3.7) leads to the announced result.

**Corollary 3.3 (Hybrid inequality).** There exists two constants \(ε₁ = ε₁(N) > 0 \) and \(C = C(N, s) \) such that the following holds. Let \(v ∈ H¹(B₁⁺; R^d, y^α dx)\) be a minimizing weighted harmonic map with free boundary in \(B₁⁺\), and \(ξ ∈ R^d\). If
\[
\left( \int_{B₁⁺} y^α |\nabla v|^2 \, dx \right) \left( \int_{B₁⁺} y^{-α} |v - ξ|^2 \, dx + \int_{B₁⁺} y^{-α} d_{N}^2(v) \, dx \right) \leq ε₁,
\]
then
\[
\int_{B₁⁺/2} y^α |\nabla v|^2 \, dx \leq \lambda \int_{B₁⁺} y^α |\nabla v|^2 \, dx \\
+ \frac{C}{λ} \left( \int_{B₁⁺} y^{-α} |v - ξ|^2 \, dx + \int_{B₁⁺} y^{-α} d_{N}^2(v) \, dx \right)
\]
for every \(λ ∈ (0, 1)\).

**Proof.** By a classical averaging argument, we can find \(r ∈ (1/2, 1) \) such that \(v\) restricted to \(∂⁺B_r\) belongs to \(H¹(∂⁺B_r; R^d, y^α dx)\), and
\[
\int_{∂⁺B_r} y^{-α} |v - ξ|^2 \, dH^1 \leq 12 \int_{B₁⁺} y^{-α} |u - ξ|^2 \, dx,
\]
\[
\int_{∂⁺B_r} y^{-α} d_{N}^2(v) \, dH^1 \leq 12 \int_{B₁⁺} y^{-α} d_{N}^2(u) \, dx,
\]
\[
\int_{∂⁺B_r} y^α |\partial_γ v|^2 \, dH^1 \leq 12 \int_{B₁⁺} y^α |\nabla v|^2 \, dx.
\]
Setting \(v_r(x) := v(rx)\) for \(x ∈ ∂⁺B₁\), we deduce by scaling that \(v_r\) satisfies (3.1) for \(ε₁\) small enough. Denote by \(w_r\) the extension of \(v_r\) provided by Lemma 3.2, and set \(w(x) := w(x/r)\) for \(x ∈ B₁⁺\). Scaling back, we discover that
\[
\int_{B₁⁺} y^α |\nabla w|^2 \, dx \\
\leq C \left( \int_{∂⁺B_r} y^α |\partial_γ v|^2 \, dH^1 \right)^{1/2} \left( \int_{∂⁺B_r} y^{-α} |v - ξ|^2 \, dH^1 + \int_{∂⁺B_r} y^{-α} d_{N}^2(v) \, dH^1 \right)^{1/2}.
\]
Since \(w = v\) on ∂⁺B_r, and \(w(x) ∈ N\) on ∂⁺B₁⁺, we may extend \(w\) by \(v\) in \(B₁⁺ \setminus B_r⁺\) to produce a competitor to minimality, that we still denote by \(w\). Hence, we have
\[ E_s(v, B_1^+) \leq E_s(w, B_1^+) \], which leads to
\[
\int_{B_{1/2}^+} y^a|\nabla v|^2 \, dx \leq \int_{B_1^+} y^a|\nabla v|^2 \, dx \\
\leq \int_{B_1^+} y^a|\nabla v|^2 \, dx \\
\leq \frac{\lambda}{12} \int_{\partial^+ B_r} y^a|\partial_r v|^2 \, dH^1 \\
+ \frac{3}{\lambda} \left( \int_{\partial^+ B_r} y^{-a}|v - \xi|^2 \, dH^1 + \int_{\partial^+ B_r} y^{-a}d_N^2(v) \, dH^1 \right) \\
\leq \lambda \int_{B_1^+} y^a|\nabla v|^2 \, dx \\
+ \frac{36}{\lambda} \left( \int_{B_1^+} y^{-a}|v - \xi|^2 \, dx + \int_{B_1^+} y^{-a}d_N^2(v) \, dx \right)
\]
for every \( \lambda \in (0, 1) \).

**3.2. Small energy regularity.** We shall now prove the aforementioned small energy regularity property. As usual, the cornerstone argument is an energy improvement under a small oscillation condition. This leads to an improved energy decay, which in turn implies Hölder continuity as in the classical Morrey’s lemma.

**Theorem 3.4 (Energy improvement).** There exist constants \( r_0 = r_0(s, N) \in (0, 1/2) \) and \( \epsilon_2 = \epsilon_2(s, N) > 0 \) such that the following holds. If \( v \in H^1(B_1^+; \mathbb{R}^d, y^a \, dx) \) is a minimizing weighted harmonic map in \( B_1^+ \) satisfying \( E_s(v, B_1^+) \leq \epsilon_2^2 \), then
\[
\frac{1}{r_0^{1-2s}}E_s(v, B_{r_0}^+) < \frac{1}{2}E_s(v, B_1^+).
\]

Let us start with the following elementary lemma inspired from [4, Lemma 3.3].

**Lemma 3.5.** Let \( v \in H^1(B_1^+; \mathbb{R}^d, y^a \, dx) \) be such that \( v(x) \in N \) for a.e. \( x \in \partial^0 B_1^+ \). Setting
\[
\bar{v} := \frac{2}{\pi} \int_{B_1^+} v \, dx,
\]
one has
\[
d_N(\bar{v}) \leq C \left( E_s(v, B_1^+) \right)^{1/2}
\]
for some constant \( C = C(s) \).

**Proof.** Since \( d_N \) is 1-Lipschitz, we have \( d_N(\bar{v}) \leq |v - \bar{v}| + d_N(v) \), and \( d_N(v) \in H^1(B_1^+, y^a \, dx) \) satisfies \( d_N(v) = 0 \) on \( \partial^0 B_1^+ \). Applying Poincaré’s inequalities, and Hölder’s inequality,
\[
d_N(\bar{v}) \leq C \int_{B_1^+} |v - \bar{v}| \, dx + C \int_{B_1^+} d_N(v) \, dx \\
\leq C \int_{B_1^+} |\nabla v| \, dx + C \int_{B_1^+} |\nabla (d_N(v))| \, dx \\
\leq C \left( E_s(v, B_1^+) \right)^{1/2}
\]
where we have used again the fact that \( d_N \) is 1-Lipschitz in the last inequality.

**Proof of Theorem 3.4. Step 1.** We argue by contradiction assuming that for a given radius \( r_0 \in (0, 1/2) \) (to be chosen), there is a sequence \( \{v_n\} \) in \( H^1(B_1^+; \mathbb{R}^d, y^a \, dx) \) of minimizing weighted harmonic maps in \( B_1^+ \) such that
\[
\epsilon_n^2 := E_s(v_n, B_1^+) \to 0, \tag{3.9}
\]
and
\[
\frac{1}{r_0^{1-2s}}E_s(v_n, B_{r_0}^+) \geq \frac{1}{2}E_s(v_n, B_1^+). \tag{3.10}
\]
By Lemma 3.5, we have $d_N(\bar{v}_n) \leq C\varepsilon_n \rightarrow 0$. Hence, for $n$ large enough, there is a unique $p_n \in \mathcal{N}$ such that $d_N(\bar{v}_n) = |v_n - p_n|$. Extracting a subsequence, there are $p \in \mathcal{N}$ and $q \in \mathbb{R}^d$ such that

$$p_n \rightarrow p, \quad \bar{v}_n \rightarrow p, \quad \text{and} \quad \frac{p_n - \bar{v}_n}{\varepsilon_n} \rightarrow q.$$ 

Note that $q \in \text{Nor}(p, \mathcal{N})$ since $p_n - \bar{v}_n \in \text{Nor}(p_n, \mathcal{N}).$

By Poincaré’s inequality in $H^1(B_1^+; \mathbb{R}^d, y^d dx)$ (see [8]), $v_n \rightarrow p$ in $L^2(B_1^+, y^d dx)$, and therefore in $H^1(B_1^+; \mathbb{R}^d, y^d dx)$. By the compact embedding, $\Pi_{\partial^0 B_1^+}$, we then have $v_n \rightarrow p$ in $L^2(\partial^0 B_1^+)$, and thus $v_n \rightarrow p$ a.e. on $\partial^0 B_1^+$, up to a further subsequence.

Consider now the sequence

$$w_n := \frac{1}{\varepsilon_n}(v_n - \bar{v}_n)$$

which satisfies

$$\text{E}_n(w_n, B_1^+) = 1 \quad \text{and} \quad \int_{B_1^+} w_n \, dx = 0.$$ 

By Poincaré’s inequality again, $\{w_n\}$ is bounded in $H^1(B_1^+; \mathbb{R}^d, y^d dx)$, and we can find a (not relabeled) subsequence such that $w_n \rightarrow w$ weakly in $H^1(B_1^+; \mathbb{R}^d, y^d dx)$. By linearity, since $v_n$ solves (2.1) in $B_1^+$, $w_n$ solves (2.1) as well in $B_1^+$. Consequently, by weak convergence, $w$ satisfies

$$\text{div}(y^d \nabla w) = 0 \quad \text{in} \quad B_1^+. \quad (3.11)$$

Next, by continuity of the trace operator, we also deduce that $\{w_n\}$ is bounded in $L^2(\partial^0 B_1^+)$. From Lemma 2.3, we also infer that $\{w_n\}$ is bounded in $H^1_{\text{loc}}(\partial^0 B_1^+)$. By the compact embedding $H^1_{\text{loc}}(\partial^0 B_1^+) \hookrightarrow L^2_{\text{loc}}(\partial^0 B_1^+)$, we deduce that, up to a subsequence, $w_n \rightarrow w$ a.e. on $\partial^0 B_1^+$ and strongly in $L^2_{\text{loc}}(\partial^0 B_1^+)$. For $x \in \partial^0 B_1^+$, such that $w_n(x) \rightarrow w(x)$ and $v_n(x) \rightarrow p$, the sequence

$$\varepsilon_n^{-1}(v_n(x) - p_n) = w_n(x) + \varepsilon_n^{-1}(\bar{v}_n - p_n)$$

is converging toward a vector in $\text{Tan}(p, \mathcal{N})$ since $v_n(x) \rightarrow p$ and $p_n \rightarrow p$. Therefore,

$$w(x) - q \in \text{Tan}(p, \mathcal{N}) \quad \text{for a.e.} \quad x \in \partial^0 B_1^+. \quad (3.12)$$

Step 2. We claim that

$$\int_{B_1^+} y^d \nabla w \cdot \nabla \zeta \, dx = 0 \quad (3.13)$$

for every $\zeta \in C^1(B_1^+; \mathbb{R}^d)$ satisfying $\zeta(x) \in \text{Tan}(p, \mathcal{N})$ for every $x \in \partial^0 B_1^+$, and such that $\text{spt}(\zeta) \subseteq B_1^+ \cup \partial^0 B_1^+$.

To prove (3.13), we consider the field $\Pi_{\zeta}$ of $d \times d$ matrices associating to $b \in \mathcal{N}$ the orthogonal projector on $\text{Tan}(b, \mathcal{N})$. Then we consider a (smooth) compactly supported extension of $\Pi_{\zeta}$ to the whole $\mathbb{R}^d$. Then $\Pi_{v_n} \rightarrow \Pi_{\zeta}$ strongly in $H^1(B_1^+; \mathbb{R}^{d \times d}, y^d dx)$. As a consequence, $\Pi_{v_n} \zeta \rightarrow \Pi_{\zeta} \zeta$ strongly in $H^1(B_1^+; \mathbb{R}^{d \times d}, y^d dx)$. Since $v_n(x) \rightarrow p$ a.e. $x \in \partial^0 B_1^+$, we have $\Pi_{v_n(x)} \zeta(x) \in \text{Tan}(v_n(x), \mathcal{N})$ for a.e. $x \in \partial^0 B_1^+$, and thus (2.2) can be applied, i.e.,

$$\int_{B_1^+} y^d \nabla v_n \cdot \nabla (\Pi_{v_n} \zeta) \, dx = 0.$$ 

Therefore,

$$\int_{B_1^+} y^d \nabla w_n \cdot \nabla (\Pi_{v_n} \zeta) \, dx = 0.$$ 

Since $\{w_n\}$ is weakly convergent and $\Pi_{v_n} \zeta$ strongly convergent, we can pass to the limit $n \rightarrow \infty$ to derive

$$\int_{B_1^+} y^d \nabla w \cdot \nabla (\Pi_{\zeta} \zeta) \, dx = 0. \quad (3.14)$$

Since $\Pi_{\zeta} \zeta - \zeta = 0$ on $\partial^0 B_1^+$, we infer from (3.11) that

$$\int_{B_1^+} y^d \nabla w \cdot \nabla (\Pi_{\zeta} \zeta - \zeta) \, dx = 0. \quad (3.15)$$
Gathering (3.14) and (3.15) yields (3.13).

Step 3. Set

\[(v_n)_{2r_0} := \int_{B_{2r_0}^+} w_n \, dx, \quad (w_n)_{2r_0} := \int_{B_{2r_0}^+} w_n \, dx \quad \text{and} \quad (w)_{2r_0} := \int_{B_{2r_0}^+} w \, dx.\]

Since the embedding \(H^1(B_1^+, y^a \, dx) \hookrightarrow L^2(B_1^+, y^{-a} \, dx)\) is compact (see e.g. [12]), we have Poincaré’s inequalities telling us that

\[
\frac{1}{(2r_0)^{1+2s}} \int_{B_{2r_0}^+} y^{-a} \left| v_n - (v_n)_{2r_0} \right|^2 \, dx \leq \frac{C}{(2r_0)^{1+2s}} E_s(v_n, B_{2r_0}^+) \leq C E_s(v_n, B_1^+),
\]

and

\[
\frac{1}{(2r_0)^{1+2s}} \int_{B_{2r_0}^+} y^{-a} d^2_X(v_n) \, dx \leq \frac{C}{(2r_0)^{1+2s}} E_s(v_n, B_{2r_0}^+) \leq C E_s(v_n, B_1^+).
\]

Here we have used the monotonicity formula in Lemma 2.5, the fact that the function \(d_N\) is 1-Lipschitz, and \(d_N(v_n) = 0\) on \(\partial^0 B_1^+\). Changing variables, one discovers that the rescaled map \(x \mapsto v_n(2r_0 x)\) satisfies the small oscillation condition in Corollary 3.3 with \(\xi = (v_n)_{2r_0}\) for \(n\) large enough, thanks to (3.9). Choosing \(\lambda = 1/8\) in that corollary and scaling back, we infer that

\[
\frac{1}{r_0^{1-2s}} E_s(v_n, B_{r_0}^+) \leq \frac{1}{8(2r_0)^{1-2s}} E_s(v_n, B_{2r_0}^+)
\]

\[
\quad + \frac{C}{\lambda(2r_0)^{1+2s}} \left( \int_{B_{r_0}^+} y^{-a} \left| v_n - (v_n)_{2r_0} \right|^2 \, dx + \int_{B_{2r_0}^+} y^{-a} d^2_X(v_n) \, dx \right).
\]

By Lemma 2.5 again, we have

\[
\frac{1}{8(2r_0)^{1-2s}} E_s(v_n, B_{2r_0}^+) \leq \frac{\varepsilon_n^2}{8}.
\]

Then,

\[
\int_{B_{2r_0}^+} y^{-a} \left| v_n - (v_n)_{2r_0} \right|^2 \, dx \leq \varepsilon_n^2 \int_{B_{r_0}^+} y^{-a} \left| w_n - (w_n)_{2r_0} \right|^2 \, dx
\]

\[
\quad \leq C \varepsilon_n^2 \left( \int_{B_{2r_0}^+} y^{-a} \left| w - (w)_{2r_0} \right|^2 \, dx + \int_{B_{2r_0}^+} y^{-a} \left| (w)_{2r_0} - (w_n)_{2r_0} \right|^2 \, dx \right).
\]

By the two compact embeddings \(H^1(B_1^+, y^a \, dx) \hookrightarrow L^1(B_1^+)\) and \(H^1(B_1^+, y^a \, dx) \hookrightarrow L^2(B_1^+, y^{-a} \, dx)\), we have \(w_n \to w\) strongly in \(L^2(B_1^+, y^{-a} \, dx)\) and \((w_n)_{2r_0} \to (w)_{2r_0}\).

Hence,

\[
\int_{B_{2r_0}^+} y^{-a} \left| v_n - (v_n)_{2r_0} \right|^2 \, dx = \varepsilon_n^2 \int_{B_{2r_0}^+} y^{-a} \left| w - (w)_{2r_0} \right|^2 \, dx + o(\varepsilon_n^2).
\]

Next we decompose the map \(w\) as \(w = w^T + w^\perp\) where \(w^T\) takes values in \(\text{Tan}(p,N)\), and \(w^\perp\) takes values in \(\text{Nor}(p,N)\). From (3.11) and (3.12), we derive that

\[
\begin{align*}
\text{div}(y^a \nabla w^\perp) &= 0 \quad \text{in } B_1^+, \\
\quad w^\perp &= q \quad \text{on } \partial^0 B_1^+.
\end{align*}
\]

From the boundary condition, we can reflect oddy the map \((w^\perp - q)\) to the whole ball \(B_1\), so that the resulting \(w^\perp\) belongs to \(H^1(B_1, y^a \, dx)\) and satisfies

\[
\text{div}(|y|^a \nabla w^\perp) = 0 \quad \text{in } B_1.
\]

By the regularity result in [8], \(w^\perp\) is \(\alpha\)-Hölder continuous in \(\overline{B}_{1/2}\) for some Hölder exponent \(\alpha = \alpha(s) \in (0, 1)\). Consequently,

\[
\int_{B_{2r_0}^+} y^{-a} \left| w^\perp - (w^\perp)_{2r_0} \right|^2 \, dx \leq C r_0^{1+2s+2\alpha}.
\]
Next we deduce from (3.13) that
\[ \int_{B_1^+} y^a \nabla w^T \cdot \nabla \zeta \, dx = 0 \]
for every \( \zeta \in C^1(\overline{B_1^+}; \Tan(p, N)) \) such that \( \text{spt}(\zeta) \subseteq B_1^+ \cup \partial^0 B_1^+ \). If we reflect even \( w^T \) to the whole ball \( B_1 \), then \( w^T \) belongs to \( H^1(B_1, |y|^a \, dx) \) and satisfies
\[ \text{div}(|y|^a \nabla w^T) = 0 \quad \text{in} \ B_1. \]
Once again, [8] tells us that \( w^T \) is \( \alpha \)-Hölder continuous in \( \overline{B_1/2} \), and thus
\[ \int_{B_{2r_0}^+} y^{-a} |w^T - (w^T)_{2r_0}|^2 \, dx \leq C r_0^{1+2\alpha+2\alpha}. \tag{3.20} \]
In view of (3.18), (3.19) and (3.20), we have proved that
\[ \int_{B_{2r_0}^+} y^{-a} |v_n - (v_n)_{2r_0}|^2 \, dx \leq C \varepsilon_n^2 r_0^{1+2\alpha+2\alpha} + o(\varepsilon_n^2). \tag{3.21} \]
Finally, to estimate the last term in the right hand side of (3.16), we proceed as follows. First notice that \( d_N(v_n) \leq \varepsilon_n |v_n| + |p_n - p_n| \), so that \( \varepsilon_n^{-1} d_N(v_n) \) is bounded in \( L^2(B_1^+, y^a \, dx) \). Since \( d_N \) is 1-Lipschitz, we have \( |\nabla d_N(v_n)| \leq \varepsilon_n |\nabla v_n| \), and thus \( \{ \varepsilon_n^{-1} d_N(v_n) \} \) is bounded in \( H^1(B_1^+, y^a \, dx) \). Since the embedding \( H^1(B_1^+, y^a \, dx) \hookrightarrow L^2(B_1^+, y^a \, dx) \) is compact, we can assume that \( \varepsilon_n^{-1} d_N(v_n) \to d \) in \( L^2(B_1^+, y^a \, dx) \) for some function \( d \in H^1(B_1^+, y^a \, dx) \). Up to a further subsequence, we also have \( v_n(x) \to a, v_n(x) \to w(x) \), and \( \varepsilon_n^{-1} d_N(v_n(x)) \to d(x) \) for a.e. \( x \in B_1^+ \).
Given \( x \in B_1^+ \) such that these convergences hold at \( x \), we have
\[ \varepsilon_n^{-1}(v_n(x) - p_n) = w_n(x) + \varepsilon_n^{-1}(a_n - p_n) \to w(x) - q. \]
On the other hand, for \( n \) large enough, \( v_n(x) \) has a unique nearest point \( v_n \in N \), and \( v_n \to p \). Since \( |v_n(x) - p_n| \geq d_N(v_n(x)) = |v_n(x) - v_n| \) and \( v_n(x) - v_n \in \text{Nor}(v_n, N) \), \( \varepsilon_n^{-1}(v_n(x) - v_n) \to n \) for some \( n \in \text{Nor}(p, N) \), taking a subsequence if necessary. In turn, it implies that \( \varepsilon_n^{-1}(v_n - p_n) \) is converging toward a vector \( t \in \Tan(p, N) \). Consequently, \( t + n = w(x) - q \), so that \( n = w^+(x) - q \), and thus \( d(x) = |w^+(x) - q| \).
We have thus shown that \( \varepsilon_n^{-1} d_N(v_n) \to |w^+ - q| \) a.e. in \( B_1^+ \), and therefore in \( L^2(B_1^+, y^a \, dx) \). Hence,
\[ \int_{B_{2r_0}^+} y^{-a} d_N^2(v_n) \, dx = \varepsilon_n^2 \int_{B_{2r_0}^+} y^{-a} |w^+ - q|^2 \, dx + o(\varepsilon_n^2). \]
Since \( w^+ \) is \( \alpha \)-Hölder continuous in \( \overline{B_{1/2}} \) and \( w^+ - q = 0 \) on \( \partial^0 B_1^+ \), we conclude that
\[ \int_{B_{2r_0}^+} y^{-a} d_N^2(v_n) \, dx \leq C \varepsilon_n^2 r_0^{1+2\alpha+2\alpha} + o(\varepsilon_n^2). \tag{3.22} \]
Gathering (3.16), (3.17), (3.21), and (3.22) yields
\[ \frac{1}{r_0^{1-2\alpha}} E_x(v_n, B_{r_0}^+) \leq \frac{\varepsilon_n^2}{8} + C \varepsilon_n^2 r_0^{2\alpha} + o(\varepsilon_n^2). \]
Choosing \( r_0 \) small enough (in such a way that \( C r_0^{2\alpha} \leq 1/8 \)), we conclude that
\[ \frac{1}{r_0^{1-2\alpha}} E_x(v_n, B_{r_0}^+) < \frac{\varepsilon_n^2}{2} \]
for \( n \) large enough, contradicting (3.10).

Arguing exactly as [9, Theorem 2.5], we infer from Theorem 3.4 the following decay estimate.

**Corollary 3.6 (Energy decay).** If \( v \in H^1(B_{2R}^+, \mathbb{R}^d, y^a \, dx) \) is a minimizing weighted harmonic map in \( B_{2R}^+ \) satisfying \( E_x(v, B_{2R}^+) \leq \varepsilon_2^2 R^{1-2\alpha} \), then
\[ \frac{1}{r^{1-2\alpha}} E_x(v, B_r^+(x)) \leq CR^{-\beta} r^\beta \quad \text{for all} \ x \in \partial^0 B_R^+ \quad \text{and} \ 0 < r \leq R, \]
for some exponent \( \beta \in (0, 1) \) depending only on \( s \) and \( N \).
In turn, this last corollary implies Hölder continuity at the boundary as in Morrey’s lemma.

**Corollary 3.7.** In addition to Corollary 3.6, \( v \) is Hölder continuous on \( \partial^0 B_R^+ \) with Hölder exponent \( \beta/2 \).

**Proof.** Combining Corollary 3.6 with Lemma 2.3, we first infer that
\[
\frac{1}{r^{1+2s}} \int_{\omega_\tau(x_0) \times \omega_\tau(x_0)} \frac{|v(x) - v(y)|^2}{|x - y|^{1+2s}} \, dx \, dy \leq CR^{-\beta} r^{-\beta}
\]
for every \( x_0 = (x_0, 0) \in \partial^0 B_R^+ \) and \( 0 < r \leq R \), where we have set \( \omega_\tau(x_0) := \partial^0 B_R^+(x_0) \).

Setting
\[
(v)_{x_0,r} := \frac{1}{2r} \int_{\omega_\tau(x_0)} v \, dx,
\]
we deduce from Poincaré’s inequality in \( H^s(\omega_\tau(x_0)) \) that
\[
\frac{1}{r^2} \int_{\omega_\tau(x_0)} |v - (v)_{x_0,r}|^2 \, dx \leq \frac{C}{r^{1+2s}} \int_{\omega_\tau(x_0) \times \omega_\tau(x_0)} \frac{|v(x) - v(y)|^2}{|x - y|^{1+2s}} \, dx \, dy \leq CR^{-\beta} r^{-\beta},
\]
for all \( x_0 \in \omega_R(0) \) and \( 0 < r \leq R \). The conclusion then follows from Campanato’s criterion (see e.g. [13, Chapter 6.1]). \( \square \)

### 4. Compactness of minimizing \( s \)-harmonic maps

This section is devoted to compactness of minimizing \( s \)-harmonic maps. As it will be clear in a few lines, the proof is here much simpler compare to classical harmonic maps, as minimality can be directly tested (as if the exterior condition were fixed). Consequences concerning the extensions and densities are then easy exercises.

**Theorem 4.1.** Let \( \omega \subseteq \mathbb{R} \) be a bounded open interval, and \( \{u_n\}_{n \in \mathbb{N}} \subseteq \tilde{H}^s(\omega;\mathcal{N}) \) a sequence of minimizing \( s \)-harmonic maps in \( \omega \). Assume that \( \sup_n \mathcal{E}_s(u_n, \omega) < \infty \), and \( u_n \to u \) in \( L^2_{\text{loc}}(\mathbb{R}) \). Then \( u \in \tilde{H}^s(\omega;\mathcal{N}) \) is a minimizing \( s \)-harmonic map in \( \omega \), \( u_n \to u \) strongly in \( H^s_{\text{loc}}(\omega) \), and \( \mathcal{E}_s(u_n, \omega') \to \mathcal{E}_s(u, \omega') \) for every open interval such that \( \omega' \subseteq \omega \).

**Proof.** First we select a subsequence \( u_k := u_{n_k} \) such that \( u_k \to u \) a.e. on \( \mathbb{R} \), and
\[
\lim_{k \to \infty} \mathcal{E}_s(u_k, \omega) = \liminf_{n \to \infty} \mathcal{E}_s(u_n, \omega) < \infty.
\]
Since each \( u_k \) takes values into \( \mathcal{N} \), we infer from the pointwise convergence that \( u(x) \in \mathcal{N} \) for a.e. \( x \in \mathbb{R} \). Then, by Fatou’s lemma, we have
\[
\mathcal{E}_s(u, \omega) \leq \lim_{k \to \infty} \mathcal{E}_s(u_k, \omega),
\]
so that \( u \in \tilde{H}^s(\omega;\mathcal{N}) \).

Let us now consider \( \tilde{u} \in \tilde{H}^s(\omega;\mathcal{N}) \) such that \( \text{spt}(u - \tilde{u}) \subseteq \omega \). We select an open interval \( \omega' \) such that \( \text{spt}(u - \tilde{u}) \subseteq \omega' \) and \( \omega' \subseteq \omega \). Define
\[
\tilde{u}_k(x) := \begin{cases} 
\tilde{u}(x) & \text{if } x \in \omega', \\
u_k & \text{if } x \in \mathbb{R} \setminus \omega'.
\end{cases}
\]
It is elementary to check that \( \tilde{u}_k \in \tilde{H}^s(\omega;\mathcal{N}) \), and of course \( \text{spt}(\tilde{u}_k - u_k) \subseteq \omega \). By minimality of \( u_k \), we have
\[
\mathcal{E}_s(u_k, \omega') \leq \mathcal{E}_s(\tilde{u}_k, \omega')
\]
which leads to
\[
\mathcal{E}_s(u_k, \omega') \leq \mathcal{E}_s(\tilde{u}_k, \omega') = \frac{\gamma_s}{2} \int_{\omega' \times \omega'} \frac{|\tilde{u}(x) - \tilde{u}(y)|^2}{|x - y|^{1+2s}} \, dx \, dy + \frac{\gamma_s}{2} \int_{\omega' \times (\mathbb{R} \setminus \omega')} \frac{|\tilde{u}_k(x) - u_k(y)|^2}{|x - y|^{1+2s}} \, dx \, dy.
\]
Since \( \tilde{u} \) and \( u_k \) are taking values in \( \mathcal{N} \), we have
\[
\frac{|\tilde{u}(x) - u_k(y)|^2}{|x - y|^{1+2s}} \leq \frac{C}{|x - y|^{1+2s}} \in L^1(\omega' \times (\mathbb{R} \setminus \omega')).
\]
Hence $\mathcal{E}_s(\tilde{u}_k, \omega') \to \mathcal{E}_s(\tilde{u}, \omega')$ by dominated convergence and the fact that $\tilde{u} = u$ a.e. in $\mathbb{R} \setminus \omega'$. On the other hand, $\liminf_k \mathcal{E}_s(u_k, \omega') \geq \mathcal{E}_s(u, \omega')$, still by Fatou’s lemma. Letting $k \to \infty$ in (4.1), we can now conclude that $\mathcal{E}_s(u, \omega') \leq \mathcal{E}_s(\tilde{u}, \omega')$. Once again, since $\tilde{u} = u$ a.e. in $\mathbb{R} \setminus \omega'$, this yields $\mathcal{E}_s(u, \omega) \leq \mathcal{E}_s(\tilde{u}, \omega)$. We have thus proved that $u$ is a minimizing s-harmonic map in $\omega$.

In addition, the argument above applied to $\tilde{u} = u$ shows that $\mathcal{E}_s(u_k, \omega') \to \mathcal{E}_s(u, \omega')$. In turn, again by dominated convergence, we have

$$\int_{\omega' \times (\mathbb{R} \setminus \omega')} \left| u_k(x) - u_k(y) \right|^2 \frac{1}{|x - y|^{1+2s}} \, dx \, dy \to \int_{\omega' \times (\mathbb{R} \setminus \omega')} \left| u(x) - u(y) \right|^2 \frac{1}{|x - y|^{1+2s}} \, dx \, dy,$$

so that $u_k \rightharpoonup u$, strongly in $H^s(\omega')$. Hence, $u_k \to u$ pointwise, and we have $u_k \to u$ weakly in $H^s(\omega')$. Then (4.2) implies that $u_k \to u$ strongly in $H^s(\omega')$.

**Theorem 4.2.** In addition to Theorem 4.1, $\tilde{u}_n \to u$ strongly in $H^1(\Omega; \mathbb{R}^d, y^d \, dx)$ for every bounded admissible open set $\Omega \subseteq \mathbb{R}^2_+$ such that $\partial^\Omega \Omega \subseteq \omega$.

**Proof.** From Theorem 4.1 and [15, Lemma 2.10], we start deducing that $u_n^c \to u^c$ strongly in $L^1(\mathbb{R}^2_+; \mathbb{R}^d, y^d \, dx)$. Since $u^c$ solves (2.3), we infer from standard elliptic theory that $u_n^c \to u^c$ strongly in $H^1_{ad}(\mathbb{R}^2_+; \mathbb{R}^d, y^d \, dx)$. It remains to prove that strong convergence holds up to $\partial^\Omega \Omega$ (locally). To this purpose, let us fix an arbitrary half ball $B_{r^2}(x_0)$ such that $x_0 \in \partial^\Omega \Omega$ and $\partial^\Omega B_{r^2}(x_0) \subseteq \omega$. By [15, Lemma 2.10], we have

$$E_s(u_n^c - u^c, B_{r^2}(x_0)) \leq C \left( E_s(u_n - u, \partial^\Omega B_{r^2}(x_0)) + \|u_n - u\|_{L^2(\partial^\Omega B_{r^2}(x_0))} \right) \to 0,$$

again by Theorem 4.1.

**Corollary 4.3.** In addition to Theorem 4.1, if $\{x_n\} \subseteq \omega$ is a sequence converging to $x$ as $n \to \infty$, then

$$\limsup_{n \to \infty} \Theta_{u_n^c}(x_n) \leq \Theta_{u^c}(x).$$

**Proof.** Without loss of generality we may assume that $x = 0$. For $r > 0$ small enough we have $\partial^\Omega B_{r^2} \subseteq \omega$. Setting $r_n := |x_n|$, we have $r_n < r$ for $n$ large enough. Then, we infer from Corollary 2.6 that

$$\Theta_{u_n^c}(x_n) \leq \Theta_{u_n^c}(x_n, r) \leq \frac{1}{1 - 2s} E_s(u_n^c, B_{r^2}(x_0)).$$

By Theorem 4.2, we have $u_n^c \to u^c$ strongly in $H^1(B_{r^2}; \mathbb{R}^d, y^d \, dx)$, and thus

$$\limsup_{n \to \infty} \Theta_{u_n^c}(x_n) \leq \lim_{n \to \infty} \frac{1}{1 - 2s} E_s(u_n^c, B_{r^2}(x_0)) = \Theta_{u^c}(0, r).$$

Letting now $r \downarrow 0$ provides the desired conclusion.

**5. Proof of Theorems 1.1 & 1.2**

This section is devoted to the proof of Theorem 1.1 and 1.2. We consider for the entire section a bounded open set $\omega \subseteq \mathbb{R}$, and $u \in H^s(\omega; \mathcal{N})$ a minimizing s-harmonic map in $\omega$. Both proofs rely on the analysis of tangent maps of $u$ at a given point in $\omega$. To define them, we fix a point $x_0 \in \omega$, and for $\rho > 0$ we consider the rescaled map

$$u_{x_0, \rho}(x) := u(x_0 + \rho x).$$

Tangent maps of $u$ at $x_0$ are all possible weak limits of $u_{x_0, \rho}$ as $\rho \downarrow 0$, and this is is the purpose of the following proposition.
Proposition 5.1 (Tangent maps). Let \( \rho_n \to 0 \) be an arbitrary sequence. There is a (not relabeled) subsequence such that \( u_{x_0, \rho_n} \to u_0 \) strongly in \( H^s_{\text{loc}}(\mathbb{R}) \), where \( u_0 \) is a minimizing \( s \)-harmonic map in every bounded open interval of the form

\[
u_0(x) := \begin{cases} a & \text{if } x > 0, \\ b & \text{if } x < 0, \end{cases}
\]

for some \( a, b \in \mathcal{N} \). In addition, \( \Theta_{u_0}^{(0)}(0, r) = \Theta_{u_0}^s(0) = \Theta_{u_0^s}(x_0) \) for every \( r > 0 \).

Proof. Assume without loss of generality that \( x_0 = 0 \) and \([-1, 1] \subseteq \omega \). For an integer \( k \geq 1 \), write \( \omega_k := (-k, k) \). For \( n \) large enough, \( 2\rho_n k \leq 1 \) and \( u_n := u_{x_0, \rho_n} \in \check{H}^s(\omega_k; \mathcal{N}) \). Moreover,

\[ E_s(u_n, \omega_k) = \frac{1}{\rho_n^{1-2s}} E_s(u, \rho_n \omega_k). \]

Next we infer from Lemma 2.3 and Lemma 2.5 that

\[ \frac{1}{\rho_n^{1-2s}} \int_{(\rho_n \omega_k) \times (\rho_n \omega_k)} \frac{|u(x) - u(y)|^2}{|x - y|^{1+2s}} \, dx dy \leq C \Theta_{u_0^s}(0, 2\rho_n k) \leq C \Theta_{u_0^s}(0, 1). \]

On the other hand,

\[ \frac{1}{\rho_n^{1-2s}} \int_{(\rho_n \omega_k) \times (\mathbb{R} \setminus \rho_n \omega_k)} \frac{|u(x) - u(y)|^2}{|x - y|^{1+2s}} \, dx dy \leq C_{\rho_n} \int_{(\rho_n \omega_k) \times (\mathbb{R} \setminus \rho_n \omega_k)} \frac{1}{|x - y|^{1+2s}} \, dx dy = C k^{1-2s}. \]

Therefore \( E_s(u_n, \omega_k) \leq C_k \) for a constant \( C_k \) depending only on \( s \) and \( k \). In particular, \( \{u_n\} \) is bounded in \( H^s(\omega_k) \) for each integer \( k \geq 1 \). Hence, we can find a (not relabeled) subsequence such that \( u_k \to u_0 \) weakly in \( H^s_{\text{loc}}(\mathbb{R}) \). From the compact embedding \( H^s(\omega_k) \hookrightarrow L^2(\omega_k) \), we also deduce that \( u_n \to u_0 \) in \( L^2_{\text{loc}}(\mathbb{R}) \). Applying Theorem 4.1 in each \( \omega_k \), we derive that \( u_0 \) is a minimizing \( s \)-harmonic map in every bounded open interval. Next, Theorem 4.2 implies that

\[ \Theta_{u_0^s}(0, r) = \lim_{n \to \infty} \Theta_{u_n^s}(0, r) = \lim_{n \to \infty} \Theta_{u_n^s}(0, \rho_n r) = \Theta_{u_0^s}(0) \forall r > 0. \]

Here, we have also used that \( u_n^s(\mathbf{x}) = u^s(\rho_n \mathbf{x}) \). In view of Corollary 2.6, we thus have

\[ \int_{B_{\mathbf{r}}^+} y^a \frac{\mathbf{x} \cdot \nabla u_0^s}{|\mathbf{x}|^{3-2s}} \, d\mathbf{x} = \Theta_{u_0^s}(0, r) - \Theta_{u_0^s}(0) = 0 \forall r > 0. \]

Therefore \( \mathbf{x} \cdot \nabla u^s = 0 \), so that \( u_0^s \) is positively 0-homogeneous, i.e., \( u_0^s(\lambda \mathbf{x}) = u_0^s(\mathbf{x}) \) for every \( \mathbf{x} \in \mathbb{R}^n_+ \) and \( \lambda > 0 \). In particular, \( u_0 \) is positively 0-homogeneous, and (5.1) follows.

Remark 5.2. If \( u \) is continuous at \( x_0 \), the limit \( u_0 \) obtained in Proposition 5.1 is obviously the constant map equal to \( u(x_0) \). As a consequence, if \( u \) is continuous at \( x_0 \), then \( \Theta_{u_0^s}(x_0, 0) = 0 \).

Proof of Theorem 1.1. Let us consider the set

\[ S := \{ x \in \omega : \Theta_{u_0^s}((x, 0)) \geq 2^{2s-1} \varepsilon_2 \}, \]

where \( \varepsilon_2 > 0 \) is the constant given by Theorem 3.4. Since \( \Theta_{u_0^s} \) is upper semicontinuous, \( S \) is a relatively closed subset of \( \omega \). Moreover, Corollaries 3.6 & 3.7 together with Corollary 2.6 implies that \( u \) is locally Hölder continuous in \( \omega \setminus S \). To prove Theorem 1.1, it then remains to show that \( S \) has no accumulation point in \( \omega \). We argue by contradiction assuming that there is a sequence \( \{x_n\} \subseteq S \) such that \( x_n \to x \in \omega \). Without loss of generality, we may assume that \( x_n > x \). Setting \( \rho_n := x_n - x \), we consider the sequence \( u_n := u_{x_n, \rho_n} \) and then apply Proposition 5.1 to find a (not relabeled) subsequence and a minimizing \( s \)-harmonic map \( u_0 \) of the form (5.1) such that \( u_n \to u_0 \).

In view of Corollary 4.3 we have

\[ \Theta_{u_0^s}((1, 0)) \geq \limsup_{n \to \infty} \Theta_{u_n^s}((1, 0)) = \limsup_{n \to \infty} \Theta_{u_n^s}((x_n, 0)) \geq \varepsilon_2. \]
On the other hand, by the explicit form (5.1), the map $u_0$ is continuous at 1. Hence, $\Theta_{a_5}((1,0)) = 0$ by Remark 5.2, contradiction.

**Proof of Theorem 1.2.** Recall that we assume now that $\mathcal{N} = \mathbb{S}^{d-1}$. In view of the proof of Theorem 1.1, it is enough to show that the set $S$ defined in (5.2) is empty. Assume by contradiction that $S \neq \emptyset$. We may then assume without loss of generality that $0 \in S$. Let $u_0$ be a $s$-minimizing harmonic map produced by Proposition 5.1, i.e., $u_0$ is the limit of the rescaled map $u_{0,n}$ for some sequence $\rho_n \to 0$. Then $\Theta_{a_5}(0) \geq \varepsilon_2 > 0$, so that $u_0$ is not constant. In other words, in the form (5.1) the two vectors $a, b \in \mathbb{S}^{d-1}$ are distinct. Upon working in the plane passing through $a$, $b$, and the origin, there is no loss of generality assuming that $d = 2$, that is $\mathcal{N} = \mathbb{S}^1$. Moreover, rotating coordinates in the image if necessary, we can assume that

$$a = (\alpha, \beta) \text{ and } b = (-\alpha, \beta),$$

with $0 < \alpha \leq 1$ and $0 \leq \beta < 1$ satisfying $\alpha^2 + \beta^2 = 1$. Then set

$$a^* := (-\beta, \alpha) \text{ and } b^* := (\beta, \alpha).$$

Note that $a^* \perp a$ and $b^* \perp b$. We define for $t \in \mathbb{R}$,

$$u_t(x) := \begin{cases} 
\frac{a + ta^*}{\sqrt{1+t^2}} & \text{if } 0 < x < 1, \\
\frac{b + tb^*}{\sqrt{1+t^2}} & \text{if } -1 < x < 0, \\
u_0(x) & \text{otherwise}.
\end{cases}$$

One can easily check that $u_t \in \tilde{H}^s((-2,2); \mathbb{S}^1)$, and since $\text{spt}(u_t - u) \subseteq (-2,2)$, the map $u_t$ is an admissible competitor for the minimality of $u_0$ in $(-2,2)$. In other words, $\mathcal{E}_s(u_0, (-2,2)) \leq \mathcal{E}_s(u_t, (-2,2))$, which in turn yields $\mathcal{E}_s(u_0, (-1,1)) \leq \mathcal{E}_s(u_t, (-1,1))$ since $u_t \equiv u_0$ outside $(-1,1)$. Therefore,

$$\left[ \frac{d}{dt} \mathcal{E}_s(u_t, (-1,1)) \right]_{t=0} = 0 \quad \text{and} \quad \left[ \frac{d^2}{dt^2} \mathcal{E}_s(u_t, (-1,1)) \right]_{t=0} \geq 0.$$

Now we expand $\mathcal{E}_s(u_t, (-1,1))$ as

$$\mathcal{E}_s(u_t, (-1,1)) = \left( \gamma_s \int_{-1}^{1} \int_{-1}^{0} \frac{dxdy}{|x-y|^{1+t^2}} \right) \frac{|(a-b) + t(a^*-b^*)|^2}{1+t^2}$$

$$+ \left( \gamma_s \int_{0}^{1} \int_{1}^{\infty} \frac{dxdy}{|x-y|^{1+t^2}} \right) \frac{|(1-\sqrt{1+t^2})a + ta|^2}{1+t^2}$$

$$+ \left( \gamma_s \int_{0}^{1} \int_{-1}^{-1} \frac{dxdy}{|x-y|^{1+t^2}} \right) \frac{|a + ta - b\sqrt{1+t^2}|^2}{1+t^2}$$

$$+ \left( \gamma_s \int_{-1}^{-1} \int_{0}^{0} \frac{dxdy}{|x-y|^{1+t^2}} \right) \frac{|1-\sqrt{1+t^2})b + tb|^2}{1+t^2}$$

$$+ \left( \gamma_s \int_{-1}^{-1} \int_{1}^{\infty} \frac{dxdy}{|x-y|^{1+t^2}} \right) \frac{|b + tb^*-a\sqrt{1+t^2}|^2}{1+t^2}.$$

It then follows that

$$\left[ \frac{d}{dt} \mathcal{E}_s(u_t, (-1,1)) \right]_{t=0} = -C\alpha\beta$$

for some constant $C = C(s) > 0$. The first order condition implies $\alpha\beta = 0$, and thus

$$a = (1,0), \ b = (-1,0), \ \text{and} \ a^* = b^* = (0,1).$$
As a consequence, using the symmetry in the integrals above,
\[
E_s(u_t, (-1, 1)) = \left( 4\gamma s \int_0^1 \int_{-1}^0 \frac{dxdy}{|x-y|^{1+2s}} \right) \frac{1}{1+t^2} + \left( 2\gamma s \int_1^\infty \int_1^\infty \frac{dxdy}{|x-y|^{1+2s}} \right) \frac{(1 - \sqrt{1+t^2})^2 + t^2}{1+t^2} + \left( 2\gamma s \int_0^1 \int_{-\infty}^{-1} \frac{dxdy}{|x-y|^{1+2s}} \right) \frac{(1 + \sqrt{1+t^2})^2 + t^2}{1+t^2}.
\]

An elementary computation now yields
\[
\left[ \frac{d^2}{dt^2} E_s(u_t, (-1, 1)) \right]_{t=0} = -8\gamma s \int_0^1 \int_{-1}^0 \frac{dxdy}{|x-y|^{1+2s}} + 4\gamma s \int_0^1 \int_1^\infty \frac{dxdy}{|x-y|^{1+2s}} - 4\gamma s \int_0^1 \int_{-\infty}^0 \frac{dxdy}{|x-y|^{1+2s}} + 4\gamma s \int_0^1 \int_{-1}^0 \frac{dxdy}{|x-y|^{1+2s}} - 4\gamma s \int_0^1 \int_{-\infty}^0 \frac{dxdy}{|x-y|^{1+2s}}
\]
\[
= -4\gamma s \int_0^1 \int_{-1}^0 \frac{dxdy}{|x-y|^{1+2s}} < 0,
\]
contradicting the second order condition for minimality.
\[\square\]
