Selection of drug resistant mutants from random library of \textit{Plasmodium falciparum} dihydrofolate reductase in \textit{Plasmodium berghei} model

Wachiraporn Tipsuwan\textsuperscript{1,2}, Somdet Srichairatanakool\textsuperscript{2}, Sumalee Kamchonwongpaisan\textsuperscript{1}, Yongyuth Yuthavong\textsuperscript{1} and Chairat Uthaipibull\textsuperscript{*}

Abstract

\textbf{Background:} The prevalence of drug resistance amongst the human malaria \textit{Plasmodium} species has most commonly been associated with genomic mutation within the parasites. This phenomenon necessitates evolutionary predictive studies of possible resistance mutations, which may occur when a new drug is introduced. Therefore, identification of possible new \textit{Plasmodium falciparum} dihydrofolate reductase (PfDHFR) mutants that confer resistance to antifolate drugs is essential in the process of antifolate anti-malarial drug development.

\textbf{Methods:} A system to identify mutations in \textit{Pfdhfr} gene that confer antifolate drug resistance using an animal \textit{Plasmodium} parasite model was developed. By using error-prone PCR and \textit{Plasmodium} transfection technologies, libraries of \textit{Pfdhfr} mutant were generated and then episomally transfected to \textit{Plasmodium berghei} parasites, from which pyrimethamine-resistant PfDHFR mutants were selected.

\textbf{Results:} The principal mutation found from this experiment was S108N, coincident with the first pyrimethamine-resistance mutation isolated from the field. A transgenic \textit{P. berghei}, in which endogenous \textit{Pbdhfr} allele was replaced with the mutant \textit{PfdhfrS108N}, was generated and confirmed to have normal growth rate comparing to parental non-transgenic parasite and also confer resistance to pyrimethamine.

\textbf{Conclusion:} This study demonstrated the power of the transgenic \textit{P. berghei} system to predict drug-resistant \textit{Pfdhfr} mutations in an \textit{in vivo} parasite/host setting. The system could be utilized for identification of possible novel drug-resistant mutants that could arise against new antifolate compounds and for prediction the evolution of resistance mutations.

\textbf{Background}

\textit{Plasmodium falciparum}, the most virulent malaria pathogen species, is responsible for nearly 863,000 deaths in 2009 \cite{1}. Malaria treatment is hampered by existence of only a limited number of drugs and the emergence of parasites resistant to most available antimalarial drugs, including chloroquine, pyrimethamine and proguanil. Therefore, there is an urgent need to search for affordable, effective and safe anti-malarials that can combat drug resistant parasites.

A bifunctional enzyme in the folate biosynthesis pathway, dihydrofolate reductase-thymidylate synthase (DHFR-TS) is a well-defined target of traditional antimalarial drugs such as pyrimethamine and cycloguanil \cite{2}. DHFR catalyses the production of tetrahydrofolate from dihydrofolate while TS is in charge of transferring a methyl-group from N5, N10-methylene-tetrahydrofolate to dUMP thereby generating dTMP and tetrahydrofolate. Mutations in Pf\textit{dhfr} gene, associated with the amino acid substitution at residues 51, 59, 108, and 164, have been found in the field with different levels of resistance to antifolate drugs \cite{3,4}. These mutations are positioned around the enzyme active site. Thus, the accumulation of point mutations in Pf\textit{dhfr} reduces the affinity of antifolate drugs such as pyrimethamine for the enzyme leading to
drug resistance [5,6]. These correlations of drug resistance with mutations in Pf\textit{dhfr} gene have been experimentally verified by comparison of mutant enzymes in transfected parasites [7]. Despite the emergence of resistant Pf\textit{dhfr} mutants in malaria endemic areas, the elucidation and development of target based screening models [8,9] and the solution of the crystal structure of PfDHFR-TS [10] means that this enzyme is still an attractive target for drug development. Therefore, in order to develop new compounds against drug resistant parasites, prediction of possible future resistance mutations becomes a priority.

Studies of mutant PfDHFR-TS expression in non-Plasmodium surrogate systems, such as Escherichia coli and Saccharomyces cerevisiae have successfully identified novel mutant Pf\textit{dhfr} alleles that confer antifolate drug resistance [8,11]. These systems have also been useful in testing new compounds against the enzyme [8,9]. However, the biochemical activities of some mutant enzymes isolated using these systems have been shown to be significantly lower than the wild-type enzyme [11]. The physiology of these surrogate cells are markedly different from \textit{Plasmodium} parasites, and it is not clear whether these resistant enzymes would have sufficient enzymatic activity to support parasite growth throughout all stages of the life cycle. Unfortunately owing to the narrow primate host range, suitable \textit{Plasmodium} in vivo models are not available.

Rodent malaria parasites such as \textit{Plasmodium berghei} are attractive models for human malaria, and the recent advances in DNA transfection technology allow for genetic modification of the parasite [12,13]. DNA transfection can be used to express \textit{P. falciparum} genes in \textit{P. berghei}, and thus transgenic \textit{P. berghei} parasites can be used as \textit{in vivo} surrogate models [14]. The power of the transgenic \textit{P. berghei} system to predict drug-resistant Pf\textit{dhfr} mutations in an \textit{in vivo} parasite/host setting was demonstrated. The objective was to identify mutations in Pf\textit{dhfr} that confer resistance to anti-folate drugs using a transgenic \textit{P. berghei} model. Libraries of randomly mutated Pf\textit{dhfr} were generated by PCR mutagenesis and transfected to \textit{P. berghei}. Upon transfection, resistant parasites were obtained after pyrimethamine selection and found to harbor Pf\textit{dhfr} mutant alleles. Thus, this system can be used as a \textit{Plasmodium} surrogate system for more accurate prediction and identification of antifolate-resistance mutations.

**Methods**

**Experimental animals and parasite**

For all experiments, female BALB/c mice (National Laboratory Animal Center, Mahidol University, Thailand) 4-6 weeks old and weighing 20-25 g were used for \textit{P. berghei} parasite infections. The transgenic \textit{P. berghei} parasite line MRA-867 expressing green fluorescent protein without drug-resistant selectable marker (PbGFP), kindly provided by Drs. Andrew Waters and Chris Janse of Malaria Research Group, Leiden University Medical Center, the Netherlands, was used in this study [14]. All animal work was evaluated and approved by the Ethical Committee on Animal Experimentation, National Center for Genetic Engineering and Biotechnology (BIOTEC), Thailand, and followed international guidelines for the use of animals in experimental studies.

**Construction of \textit{P. berghei} transfection plasmid**

Plasmid for \textit{P. berghei} transfaction in this study was modified from the original plasmid pL0017 [15], which was kindly provided by Drs. Andrew Waters and Chris Janse (Leiden University Medical Centre, the Netherlands). The final transfection plasmid, designated pY005, contains wild type \textit{Pfdhfr-ts} gene flanked with 1.0-kb each of 5′ and 3′ untranslated region (UTR) sequences of \textit{Pfdhfr-ts}. BamHI and AflII restriction sites were introduced at 5′ and 3′ ends, respectively, of \textit{Pfdhfr} domain to serve as cloning sites for the randomly-mutated \textit{Pfdhfr} library.

**Construction of \textit{Pfdhfr} random mutant library**

\textit{Pfdhfr} mutant library was generated by error prone PCR [11]. The 50-μL PCR reaction contained 1 ng of pY005 plasmid template harboring wild type \textit{Pfdhfr}, 10 μM of sense primer F1 (CGGTGGATCCATGATGGAAACAG; BamHI site is underlined), 10 μM of antisense primer R1 (CTTGTGATCCTATGAGCG; AflII site is underlined), 0.1 mM dGTP, 0.1 mM dATP, 0.5 mM dCTP, 0.5 mM dTTP, and 1× Mutagenesis buffer [16] and 5 units of GoTaq® DNA polymerase (Promega). The thermostable condition was: 1 cycle of 95°C for 3 min, 30 cycles of 95°C for 1 min, 50°C for 1 min, 72°C for 1 min, and final extension of 72°C for 5 min. PCR products of random mutant \textit{Pfdhfr} library of about 0.7 kb were cloned into the BamHI/AflII sites of pY005. The plasmids containing \textit{Pfdhfr} mutation libraries were grown in Luria Bertani broth containing 100 μg/ml ampicillin in a 37°C incubator shaker for 12-16 hours. Plasmids were extracted and purified using a Qiagen Spin Miniprep kit (Qiagen). Extracted plasmids were precipitated by isopropanol and re-suspended in 10 μl TE buffer (10 mM Tris, 1 mM EDTA pH 8.0) for use in transfection experiment.

**Determination of pyrimethamine sensitivity to parental and transgenic parasites**

The sensitivity of pyrimethamine to inhibit the parental PbGFP parasite or transgenic parasites expressing PfDHFR mutant was determined by the 4-day suppressive test [17]. Five groups of five BALB/c mice per group were infected intravenously (i.v.) with 1 × 10⁷ parasitized...
erythrocytes and treated with different concentration of pyrimethamine by intraperitoneal (i.p.) injection four hours post infection. The control group was treated with 5% (v/v) DMSO in PBS pH 4.0. The experimental groups were treated with different doses of pyrimethamine through the same route for another 3 days. Twenty-four hours after the last treatment (day 4), percentages of parasitaemia were determined by microscopic counting of Giemsa-stained smears from mouse tail blood.

**Statistical analysis**

All statistical analyses were carried out using SigmaPlot software version 11 (Systat Software Inc., USA). For calculation of the growth inhibitory curve, parasitaemia of the control group was set as 0% inhibition. The non-linear regression for sigmoidal dose-response (variable slope) was used to calculate the 50%, 90% or 95% effective dose (ED50, ED90 or ED95) values.

**Transfection, selection and identification of Pfdhfr random mutant libraries**

*In vitro* culture of PbGFP and *P. berghei* transfection were performed as described [13]. Briefly, parasitized blood was collected from a donor animal and cultured overnight in culture media (RPMI 1640 medium containing 20% heat inactivated fetal calf serum, 50 IU/mL neomycin and 25 mM Heps). Schizont stage parasites were purified from the overnight culture by Nycodenz gradient centrifugation. The merozoites were transfected with the circular plasmid DNA harboring Pfdhfr mutant libraries using the standard Amaxa Nucleofector protocol [13] and re-infected into animals by i.v. injection. Twenty-four hours after transfection, 0.25 mg/kg of pyrimethamine was used to treat the infected mice by i.p. injection daily until the drug resistant parasites appeared. The integrated transgenic mutant parasite clones were obtained by the limiting dilution method [18].

**PCR analysis of transgenic *P. berghei* parasite**

The correct integration of Pf\textit{dhfr}\textsubscript{S108N} sequence into the genome via the 5’ and 3’UTRs of the Pf\textit{dhfr}-ts locus was determined by PCR. A 4.0-kb DNA fragment spanning the endogenous 5’UTR Pf\textit{dhfr}-ts sequence and the introduced Pf\textit{dhfr} was indicative of an integration event and was amplified using primers F2 (TTGAGCTACA-TAACCTCATAC) and R1 (described above). A 3.0-kb DNA fragment spanning the introduced Pf\textit{dhfr} and the endogenous 3’UTR Pf\textit{dhfr}-ts sequence, indicative of a 3’ integration event was amplified using primers F1 (described above) and R2 (CGATCTACACCTCTCAT).

**Expression profile of transgenic mutant parasite**

The transgenic parasites expressed PfDHFR\textsubscript{S108N}-TS under the control of 5’ and 3’UTRs of Pf\textit{dhfr}-ts. To determine whether this promoter efficiently drives Pf\textit{dhfr}\textsubscript{S108N}-ts mRNA expression, reverse-transcription PCR (RT-PCR) was performed. Total RNA was isolated from blood stage transgenic *P. berghei* parasites using Trizol reagent (Invitrogen). cDNA was generated and used as template for amplification with gene specific primers for the Pf\textit{dhfr} transgene using primers F1 and R1 (described above). Controls included specific primers for Pf\textit{dhfr} gene: PbDTF (GGGGGCGCATATGGAGACTATTCT-GAAAACATG) and PbDTR (GGGAGTGCTCCTCAGTTG) and *P. berghei* alpha tubulin gene: Pb\textit{tubulin}F (GGCATGCACATTATGTGGG) and Pb\textit{tubulin}R (GCCGTGCTTCTGATTG). RT-PCR was performed using the same PCR condition as described above.

**Results**

**Determination of pyrimethamine sensitivity in wild type PbGFP parasites**

Experimental mice infected with wild type PbGFP parasites were treated with different concentrations of pyrimethamine. As shown in Figure 1, *in vivo* ED\textsubscript{50} and ED\textsubscript{95} of pyrimethamine against PbGFP was 0.02 mg/kg and 0.25 mg/kg, respectively. The ED\textsubscript{95} concentration of pyrimethamine was then used for selection of transgenic resistant parasites in subsequent experiments.
Construction of PfDHFR random mutant library using wild type PfDHFR template

Approximately 14,000 bacterial colonies were obtained for the PfDHFR random mutant library. Twelve colonies were randomly picked and sequenced. From the sequence alignment, up to 4 base substitutions per gene were found. The mutation frequency was then calculated as 0.26%, which is equivalent to approximately 2 base substitutions per 700 bp of PfDHFR gene. Thus, the PCR-induced mutagenesis for this library is within the expected mutation frequency of 2 to 5 base substitutions per gene [19]. The rest of the bacterial colonies were harvested for library DNA preparation.

Selection of transfected resistant mutant parasites from wild type PfDHFR random libraries

Plasmid DNA was purified from the PfDHFR random mutant library and transfected to PfGFP parasites. Pyrimethamine-resistant parasites began to appear in most transfection experiments within 11 days post-transfection. Genomic DNA containing episomal transgenic DNA was extracted from drug-resistant parasites and transformed into E. coli. Among the isolated plasmids, two independent sequences were identified. One sequence contained a single base substitution mutation at amino acid position 108 (serine, S; AGC changed to asparagine, N; AAC) while the other had the same mutation at amino acid position 108 together with another base substitution at codon 196, which was silent (phenylalanine; TTT to TTG).

Generation of transgenic P. berghei expressing PfDHFRS108N-ts mutant

In order to confirm that the S108N mutation found among library-transfected DNA from drug-resistant parasites conferred resistance, allelic replacement of the endogenous PfDHFR-ts with mutant PfDHFRS108N-ts was performed. The strategy for the allelic replacement event is shown in Figure 2. Correct integration was investigated by PCR analysis on genomic DNA using different primers pairs. PCR products obtained corresponded with the expected 4.0 kb and 3.0 kb bands for 5' and 3'UTR integration respectively, as shown in Figure 3A.

Expression profile analysis of transgenic PfDHFRS108N mutant parasite

Transgenic P. berghei parasite with integrated PfDHFRS108N-ts, named PbPS108N, expresses the gene under the control of PfDHFR-ts 5' and 3'UTRs. The expression of the enzyme was verified at the mRNA transcription level using RT-PCR. As shown in Figure 3B, 0.7 kb of PfDHFR was amplified in cDNA from transgenic PbPS108N parasite, but not in cDNA from PfGFP parental parasite. Conversely, PbDHFR was amplified only in cDNA from parental PfGFP parasite, but not in cDNA from transgenic PbPS108N parasites. The expected 0.85 kb band for the control P. berghei alpha tubulin was obtained for all parasites. No products were detected for -RT control templates, indicating that genomic DNA was absent.

Determination of growth rate and pyrimethamine sensitivity in transgenic PbPS108N parasite

The growth rate of transgenic PbPS108N parasite was compared with PfGFP parental parasite. The growth rates of the two parasites were not significantly different (Figure 4A). The efficacy of pyrimethamine to inhibit transgenic PbPS108N parasites was determined by 4-day suppressive test. The calculated ED50 and ED90 values of

pyrimethamine against transgenic \( \text{PbPfS108N} \) parasites were 1.33 mg/kg and 2.65 mg/kg, respectively (Figure 4B).

**Discussion**

There is need to identify possible drug-resistance mutations against new compounds under development as antimalarial drugs. Prior knowledge of possible resistance pathways facilitates testing of strategies for forestalling the evolution and spread of resistance in the parasite population, e.g. drug combinations. In this study, a \( \text{P. berghei in vivo} \) model was developed as a surrogate cell expression system to identify \( \text{Pfdhfr} \) mutations that confer antifolate drug resistance. This system employs DNA transfection in which the selectable marker is antifolate-resistant mutant \( \text{Pfdhfr} \), rather than the conventional \( \text{human dhfr} \) and \( \text{Toxoplasma gondii dhfr} \) markers used in \( \text{P. berghei} \) transfection [20]. The concentration of pyrimethamine at 0.25 mg/kg (ED\(_{95}\) of wild type \( \text{P. berghei} \) parasite) i.p. injection daily was successful in selecting resistant parasites obtained after transfection with \( \text{Pfdhfr} \) mutant libraries. Interestingly, the resistant parasite lines transfected with a \( \text{Pfdhfr} \) variant library were found to contain the S108N mutation, which is known to be the key antifolate resistance mutation found in nature [21]. The fact that the pyrimethamine resistant line carried this mutation provides proof of concept of this system to be able to identify drug resistant mutations from a mutant library.

\( \text{PfDHFR-TS} \) crystal structure reveals the asparagine side chain of the mutant enzyme is in steric clash with the \( \text{p-chlorophenyl moiety of pyrimethamine} \), which reduces the binding affinity of pyrimethamine for the mutant enzyme [10]. Although the selected drug-resistant library mutants contained the expressed S108N mutation, it should be noted that the drug-resistant library mutants are maintained episomally, and the increased \( \text{dhfr} \) gene copy number in episomes may contribute to drug resistance in
transgenic *P. berghei*, as has been shown for the *hgdhfr* transfection marker [20]. Thus, to test the hypothesis that pyrimethamine resistance in transgenic *P. berghei* is determined solely by the S108N mutant allele, *Pbdhfr*-ts was replaced with the *Pfdhfr* S108N-ts mutant by double homologous recombination. The integrated transgenic parasites expressed *Pfdhfr* S108N-TS with a single copy of mutant *Pfdhfr* S108N under the control of endogenous *Pbdhfr*-ts 5′ and 3′UTRs. The resulting *PbPfs108N* transgenic parasites showed susceptibility to pyrimethamine with ED₅₀ values 66-fold higher than PbGFP wild type, which strongly suggest that resistance is conferred by the S108N mutation. In addition, *PbPfs108N* transgenic parasites grew the same as PbGFP parasites. This result demonstrated that the DHFR-TS function is conserved between the two *Plasmodium* species, in agreement with other cross-species comparisons in the same genus [22]. Furthermore, the pyrimethamine resistance mutation had no negative effect on the function of the enzyme, in agreement with earlier studies [21,23]. This demonstrates the capacity of the transgenic *P. berghei* parasite model to study the fitness of *Pfdhfr* mutant alleles in the whole transmission cycle.

For pyrimethamine resistance, in addition to S108N mutation, other mutations such as S51I, C59R and I164L are known to augment the resistance level in parasites [21,23]. Although our mutant library is of sufficient diversity to contain these other mutations, they were not found among drug-selected parasites. In order to obtain transgenic parasites with a higher level of resistance, higher drug pressure will needed. However, selection of highly resistant pyrimethamine alleles with two or more mutations is not feasible, since mice could not tolerate the very high pyrimethamine doses needed.

In conclusion, a new experimental system for predicting the evolutionary pathway of antifolate drug resistance was developed. The major advantage of this system is that drug-resistant mutant alleles can be selected from diverse *Pfdhfr* libraries in a *Plasmodium* surrogate cell in a proper host background. Proof of concept for the system was demonstrated using the well-known antifolate pyrimethamine; however, new antifolates are being developed which demonstrated using the well-known antifolate pyrimethamine
