Abstract. In the VIP2 Violation of the Pauli Exclusion Principle (PEP) experiment at the Gran Sasso underground laboratory (LNGS) we are searching for possible violations of standard quantum mechanics predictions. With high precision we investigate the Pauli Exclusion Principle and the collapse of the wave function (collapse models). We will present our experimental method of searching for possible small violations of the Pauli Exclusion Principle for electrons, via the search for "anomalous" X-ray transitions in copper atoms, produced by "new" electrons (brought inside a copper bar by circulating current) which could have the probability to undergo Pauli-forbidden transition to the ground state (1s level) already occupied by two electrons. We will describe the concept of the VIP2 experiment taking data at LNGS presently. The goal of VIP2 is to test the PEP for electrons with unprecedented accuracy, down to a limit in the probability that PEP is violated at the level of $10^{-31}$. We will show preliminary experimental results obtained at LNGS and discuss implications of a possible violation.
1. Introduction
Wolfgang Pauli discovered the Exclusion Principle (PEP) named after him which could explain the periodic table of the elements [1]. Among the known rules of nature PEP is an outstanding one, which can explain important phenomena like the stability of matter, the existence/stability of neutron stars and many others. Nowadays we can trace back the PEP to the spin-statistics theorem which classifies nature according to the spin in fermionic (odd spin) and bosonic (even spin) systems. Remarkably no simple intuitive explanation for the PEP could be given. Several proofs of the PEP based on complicated arguments can be found in the literature [2, 3]. The proof by Lüders and Zumino [3] is based on a clear set of assumptions:

- Invariance with respect to the proper inhomogeneous Lorentz group
- Two operators of the same field at points separated by a spacelike interval either commute or anticommute (locality)
- The vacuum is the state of lowest energy
- The metric of the Hilbert space is positive definite
- The vacuum is not identically annihilated by a field

If at least one of these assumptions is invalid then a violation of the Pauli Principle would be possible. There are also theoretical attempts to accomplish PEP violations. Some recent theoretical studies can be found in refs. [4, 5].

2. VIP2 Experiment
2.1. Method of PEP testing
The idea behind the VIP2 experiment follows an experiment performed by Ramberg and Snow [6] with strongly improved signal sensitivity and background suppression. Like this experiment we search for Pauli forbidden X-ray transitions in copper after introducing "new" electrons to the system. The concept is based on the assumption that an electric current running through a copper conductor resembles a source of electrons which are "new" to the systems of copper atoms of the copper conductor. Thus one can search for Pauli-forbidden transitions in the copper atoms (see fig. 1). The transition energy of the PEP violating transition is shifted in energy due to the shielding by the "extra" electron in the 1s state. These shifted transition energies can be calculated using a multiconfiguration Dirac-Fock approach taking the relevant corrections (e.g. relativistic corrections) into account [7, 8].

*Figure 1.* Transitions to the 1s ground state: Allowed transition 2p-1s (left) and Pauli forbidden transition to the fully occupied 1s state (right).
Figure 2. This photo shows the interior of the VIP2 experiment. In the box the copper target, the SDDs and the plastic scintillators are mounted. An insulation vacuum ($\sim 10^{-5}$ mbar) inside the box is necessary to operate the SDDs at 100 K.

2.2. VIP2 Setup at LNGS

An experiment VIP [9, 10] following the concept of Ramberg and Snow was set up in the underground laboratory LNGS in Gran Sasso/Italy (LNGS). As X-ray detectors VIP used charge coupled devices (CCDs) [11] providing very good energy resolution, large detector solid angle and high intrinsic efficiency. The CCDs were already successfully employed in an experiment on kaonic atoms at LNF Frascati [12, 13]. The CCDs were positioned around a pure copper cylinder operated without and with up to 40 A current. The cosmic background in the LNGS site is strongly suppressed ($\sim 10^{-6}$) due to the rock coverage. Additionally the setup was covered by passive lead shielding.

To further enhance the sensitivity the experiment VIP2 with SDDs (Silicon Drift Detectors) as X-ray detectors was set up at LNGS. The experimental setup provides a larger X-ray detector solid angle, higher current and employs active shielding by plastic scintillators as background sensitive detectors. Due to the timing capability of SDDs the timing information of the SDD detectors and plastic scintillator signals can be used to additionally suppress background events.

Figure 3. The VIP2 x-ray detector with 3 SDDs mounted.
3. Preliminary Results
The progress of the VIP2 experiment has been reported in [14, 15, 16, 17]. In 2016 we collected data in a time period of ∼70 days without current and ∼40 days with 100 A current. In fig. 4 a typical x-ray spectrum of one SDD of the detector array is displayed.

With the analysis technique of Ramberg and Snow [6] we obtain a preliminary upper limit for the probability that the PEP is violated for electrons in copper

\[ \beta^2/2 \leq 2.4 \times 10^{-29} \]  

4. Summary and Outlook
The experimental program for testing a possible PEP violation for electrons made great progress in 2016. The use of a new type of SDDs as X-ray detectors can further enhance the sensitivity by providing larger sensitive area. Furthermore, the cooling can be made more simple changing from liquid argon to Peltier cooling. Concerning the reduction of the X-ray background we will install a passive shielding with Teflon, lead and copper. Given a running time of 3 years and alternating measurement with and without current we expect to lower the upper limit of PEP violation by about two orders of magnitude.

Acknowledgments
We thank H. Schneider, L. Stohwasser, and D. Pristauz-Telsnigg from Stefan-Meyer-Institut for their fundamental contribution in designing and building the VIP2 setup. We acknowledge the very important assistance of the INFN-LNGS laboratory staff during all phases of preparation,
installation and data taking. The support from the EU COST Action CA 15220 is gratefully acknowledged. We thank the Austrian Science Foundation (FWF) which supports the VIP2 project with the grants P25529-N20 and W1252-N27 (doctoral college particles and interactions) and Centro Fermi for the grant Problemi aperti nella meccanica quantistica. Furthermore, this paper was made possible through the support of a grant from the Foundational Questions Institute, FOXi (Events as we see them: experimental test of the collapse models as a solution of the measurement problem) and a grant from the John Templeton Foundation (ID 58158). The opinions expressed in this publication are those of the authors and do not necessarily reflect the views of the John Templeton Foundation.
