ABSTRACT

Objective: To development and validation of a reversed-phase high-performance liquid chromatography (RP-HPLC) for the determination of modafinil in bulk and pharmaceutical dosage forms.

Methods: A simple, precise, rapid, and accurate RP-HPLC method was developed for the estimation of modafinil in bulk and pharmaceutical dosage forms. Xterra RP 18 (250 mm × 4.6 mm, 5 μ particle size) with mobile phase consisting of methanol:water 70:30 V/V was used. The flow rate 1.0 ml/min and the effluents were monitored at 260 nm. The retention time and recovery time was 12 minutes. The detector response was linear in the concentration of 10-50 µg/ml. The respective linear regression equation being Y = 45.21x + 523.7. The limit of detection and limit of quantification were 4.547 and 1.377 mcg, respectively. The method was validated by determining its accuracy, precision, and system suitability.

Result: The objective of the present work is to develop simple, precise, and reliable HPLC method for the analysis of modafinil in bulk and pharmaceutical dosage forms. This is achieved using the most commonly employed Xterra RP 18 (250 mm × 4.6 mm, 5 μ particle size) column detection at 260 nm. The present method was validated according to ICH guidelines.

Conclusion: In this study, a simple, fast and reliable HPLC method was developed and validated for the determination of modafinil in pharmaceutical formulations.

Keywords: Modafinil, Reversed-phase high-performance liquid chromatography, Estimation, ICH guidelines, Tablets.

INTRODUCTION

Modafinil belongs to the class narcoleptics. The chemical name is 2-[(Diphenylmethyl)-sulfinyl] acetamide. This is a α-adrenergic agonist. Clinical evaluation in hypersomnia and narcolepsy. It is not official in any of the pharmacopoeia. It is listed in the Merck Index 13th edition [1] and Martindale the complete drug reference 36th edition [2]. Literature survey revealed estimation of modafinil by several techniques such as simultaneous estimation by high-performance liquid chromatography (HPLC) [3], determination of modafinil in human plasma by solid-phase and liquid-liquid extraction by HPLC [4-6] determination of modafinil in human urine by HPLC [7], determination of related substance in modafinil [8], and determination of modafinil by a chiral chromatography [9] methods have been reported. In this study, an attempt was made to develop rapid and economical spectrophotometric and reversed-phase HPLC (RP-HPLC) method for estimation of modafinil in bulk and pharmaceutical formulation with better sensitivity, precision, and accuracy using Xterra RP 18 column and UV-detector.

Experimental

Instrumentation

Quantitative HPLC was performed on liquid chromatography, Waters separation 2996, photodiode array detector (PDA) detector module equipped with automatic injector with injection volume 20 μl and 2693 pump. Xterra RP 18 (250 × 4.6 mm, 5 μ particle size) with mobile phase consisting of methanol:water 70:30 V/V was used. The flow rate was 1.0 ml/min and the effluents were monitored at 260 nm. The retention time and recovery time was 12 minutes. The detector response was linear in the concentration of 10-50 µg/ml. The respective linear regression equation being Y = 45.21x + 523.7. The limit of detection and limit of quantification were 4.547 and 1.377 mcg, respectively. The method was validated by determining its accuracy, precision, and system suitability.

Result: The objective of the present work is to develop simple, precise, and reliable HPLC method for the analysis of modafinil in bulk and pharmaceutical dosage forms. This is achieved using the most commonly employed Xterra RP 18 (250 mm × 4.6 mm, 5 μ particle size) column detection at 260 nm. The present method was validated according to ICH guidelines.

Conclusion: In this study, a simple, fast and reliable HPLC method was developed and validated for the determination of modafinil in pharmaceutical formulations.

vacuum pump and degassed by sonication to expel the dissolved gases in solvent system.

**Preparation of system suitability solution (standard solution)**
About 25 mg of modafinil standard powder was weighed and added into 25 ml volumetric flask and diluted with methanol to make the concentration 100 mcg/ml. 5 ml of this standard stock solution was pipette out and transferred into 50 ml volumetric flask and diluted with methanol to make the concentration 10 mcg/ml.

**Preparation of sample solutions**
About 20 tablets were accurately weighed, and the average weight was calculated. The tablets are grinded to a fine powder with the help of mortar and pestle. Then, the amount of powder equivalent to the average weight of a tablet was transferred to a volumetric flask, diluted with diluents, and shaken for about 10 minutes then filtered through filter paper. The filtered solution was further diluted in the mobile phase to make the final concentration of working sample equivalent to 10 mcg/ml.

**Chromatographic condition**
The samples were introduced by an injector with a 20-μl loop. The analysis was performed under isocratic conditions using a flow rate 1 ml/min at ambient temperature. Chromatograms were recorded at λ=260 nm using a detector PDA Shimadzu UV-VIS.

**METHODS**
The HPLC system was stabilized for 30 minutes by passing mobile phase, detector was set at 260 nm, flow rate of 1.0 ml/min to get a stable baseline. One blank followed by six replicates of a single standard solution was injected to check the system suitability. Six replicates of each standard solution 10, 20, 30, 40, and 50 µg/mL were injected. Calibration graph was plotted by the concentration of modafinil on X-axis and peak area on Y-axis and linearity curve was shown in Fig. 2. The amount of drug present in the sample was computed by calibration graph. Chromatographic conditions for estimation of modafinil were described in Table 1.

**RESULTS AND DISCUSSION**
The objective of the present work is to develop simple, precise and reliable HPLC method for the analysis of modafinil in bulk and pharmaceutical dosage forms. This is achieved using the most commonly employed Xterra RP 18 (250 mm × 4.6 mm, 5 μ particle size) column detection at 260 nm. The representative chromatogram indicating modafinil is shown in Fig. 1.

**Parameter fixation**
In developing this method, a systemic study of effects of various parameters was conducted by varying one parameter at a time and controlling all other parameters. The following studies were conducted for this purpose.

**Table 1: Optimized chromatographic conditions of modafinil parameters**

| Parameter                  | Solvents          |
|----------------------------|-------------------|
| Mobile phase               | Methanol:water (70:30) |
| Column                     | C18               |
| Diluents                   | Methanol          |
| Column temperature         | 30°C              |
| Wavelength                 | 260 nm            |
| Injection volume           | 20 L              |
| Flow rate                  | 1.0 ml/min        |
| Run time                   | 10                |
| Retention time             | 8.392             |

**Stationary phase characteristics**
Based on nature and solubility characteristics of RP mode of HPLC was selected azithromycin for chromatography. Among different RP-HPLC stationary phases tried Xterra RP 18 (250 × 4.6 mm, 5 μ particle size was found to be optimum).

**Mobile phase characteristics**
To get sharp peak with baseline separation from interfering peaks carried out a number of experiments by varying the composition of solvents and mobile phase flow rate. To have an ideal separation of the drug under isocratic conditions, HPLC grade methanol and water were used in the ratio of 70:30 (v/v) was proved to be the most suitable of all the combinations since the chromatographic peak obtained was better defined and resolved and almost free from tailing.
Linearity
A linearity study verifies that the sample solutions are in a concentration range where analyte response is linearly proportional to concentration. The linearity of response for the present method was determined by analyzing standard solution in the concentration range of 10-50 mcg/ml. The results showed that the peak areas are linear within the concentration of analysis. The correlation coefficient was $r^2=0.997$ (Fig. 2).

Accuracy
The accuracy of the method was determined by standard addition method. A known amount of standard drug was added to the fixed amount of pre-analyzed standard solution. The percent recovery and % relative standard deviation (%RSD) was calculated, and the results are presented in Table 3. Satisfactory recoveries ranging from 97.13%, 98.73%, 99%, 97.13%, and 97.53% were obtained by the proposed method. This indicates that the proposed method was accurate.

| Concentration | Area  |
|---------------|-------|
| 10            | 78476 |
| 20            | 83382 |
| 30            | 88382 |
| 40            | 92408 |
| 50            | 96570 |

Table 2: Linearity results of modafinil

Intra-day precision
To study the intra-day precision, three replicate standard solutions (300 ppm) of modafinil were injected. The %RSD was calculated and it was found to be 0.51 which are well within the acceptable criteria of not more than 2.0.

Inter-day precision
To study the inter-day precision, six replicate standard solutions (300 ppm) of modafinil were injected. The %RSD was calculated and it was found to be 0.42 which are well within the acceptable criteria of not more than 2.0.

Specificity
The effect of a wide range of excipients and other additives usually present in the formulation of modafinil in the determinations under optimum conditions were investigated. Chromatographic parameters maintained are specific for modafinil.

Limit of detection (LOD) and limit of quantification (LOQ)
The detection limit of the method was investigated by injecting standard solutions of modafinil into the HPLC column. By using the signal-to-noise method the peak-to-peak noise around the analyte retention time is measured, and subsequently, the concentration of the analyte that would yield a signal equal to certain value of noise to signal ratio is estimated. A signal-to-noise ratio (S/N) of 3 is generally accepted for estimating LOD and signal-to-noise ratio of 10 is used for estimating LOQ. This method is commonly applied to analytical methods that

exhibit baseline noise. The LOD and LOQ for modafinil were found to be 4.547 and 1.377 µg/ml, respectively.

**Robustness**

Robustness of the method was determined by making slight changes in the chromatographic conditions. It was observed that there were no marked changes in the chromatograms, which demonstrated that the RP-HPLC method developed is robust.

**System suitability**

A system suitability test was performed to evaluate the chromatographic parameters (number of theoretical plates, tailing of the peak) before the validation runs. The analytical method validation was carried out as per ICH method validation guidelines.

**CONCLUSION**

In this study, a simple, fast and reliable HPLC method was developed and validated for the determination of modafinil in pharmaceutical formulations. As these proposed methods have the lowest LOQ values and the wider linear range is a more sensitive method. From the results obtained, we concluded that the suggested methods showed high sensitivity, accuracy, reproducibility, and specificity. Moreover, these methods were simple and inexpensive, and these can be employed for the routine quality control of modafinil in pharmaceutical formulations [11].
