Abstract

Introduction: Gap junctions (GJs) represent the best known intercellular communication (IC) system and are membrane-spanning channels that facilitate intercellular communication by allowing small signaling molecules to pass from cell to cell. In this study, we constructed an amino terminus of human Cx43 (Cx43NT-GFP), verified the overexpression of Cx43-NT in HUVEC cells and explored the impact of gap junctions (GJs) on multiple myeloma (MM).

Material and methods: The levels of phosphorylated Cx43(s368) and the change of MAPK pathway associated molecules (ERK1/2, JNK, p38, NFκB) were also investigated in our cell models. Cx43 mRNA and proteins were detected in both MM cell lines and mesenchymal stem cells (MSCs). Dye transfer assays demonstrated that gap junction intercellular communication (GJIC) occurring via Cx43 situated between MM and MSCs or MM and HUVECCx43-N is functional.

Results: Our results present evidence for a channel-dependent modulator action of connexin 43 on the migratory activity of MM cells toward MSCs or HUVECCx43-N was higher than those of spontaneous migration ($p < 0.05$) and protection them from apoptosis in the presence of dexamethasone via cytokines secretion. In the meantime, the migration of MM cells involves an augmented response of p38 and JNK signaling pathway of carboxyl tail of the protein.

Conclusions: Our data suggest that GJIC between MM and MSCs is one of the essential factors in tumor cell proliferation and drug sensitivity, and is implicated in MM pathogenesis.

Key words: multiple myeloma, gap junction intercellular communication, migration, cellular signaling.

Introduction

Multiple myeloma (MM) is a fatal hematological malignancy that develops within the bone marrow microenvironment and is characterized by the uncontrolled clonal proliferation of malignant plasma cells within the bone marrow. It is known that MM-cell tumorigenesis results from a host of known and unknown genetic anomalies, including non-random translocations of genes that normally function as determinants of cell proliferation or cell survival to regions juxtaposed to active immunoglobulin heavy chain enhancer elements, chromosomal aneuploidy, somatic mutations that further affect oncogenic signaling and loss of
membrane-spanning channels that facilitate intercellular communication (IC) system and are pivotal in the growth and survival of malignant plas- 

cytes/macrophages, mesenchymal stem cells, adipocytes, immune cells, osteoclasts, osteoblasts and endothelial cells. Cell-to-cell contact between bone marrow stromal cells and MM cells has been recently proposed as a pivotal regulatory interaction in the growth and survival of malignant plasma cells [7, 8].

Gap junctions (GJs) represent the best known intercellular communication (IC) system and are membrane-spanning channels that facilitate intercellular communication by allowing small signaling molecules to pass from cell to cell [9]. Multiple cell types in the bone marrow microenvironment, which express Cx43, include monocytes, dendritic cells, B and T lymphocytes, as well as MM cells [10–12]. Cx43 is essential for terminal differentiation of B and T cells when tested in Cx43-deficient mice; however, when Cx43 was missing in bone marrow cells alone, T cell development was normal [10, 13]. More than 20 connexin genes have been found in human and mouse genomes, and disruption of connexin expression often results in developmental defects and lethality [14]. Besides IC, connexins, especially Cx43, which has a relatively long C-terminal cytoplasmic domain, may serve as adaptor proteins and interact with the cytoskeleton and signaling molecules such as β-catenin, Src, protein kinase C, and MAPK [15]. Our previous studies [16] also demonstrated that osteoblasts induced from bone marrow mesenchymal stem cells (MSCs) supported survival and proliferation of MM cells. However, the specific role of Cx43 in the survival and migration of MM cells remains largely unknown. Therefore, in order to investigate the role of GJIC between MM and stromal cells, we constructed Cx43-NT over-expressing cells and attempted to determine whether the signaling mediated by the Cx43 C-terminal contributes to MM cell survival and migration and whether bone marrow stromal cell mediated GJ intercellular communication (GJIC) was responsible for the MM clonal expansion but no cytokine production of activated TME.

Material and methods

Cell lines and primary specimens

The myeloma cell line RPMI-8226 was obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA) and cultured in RPMI-1640 medium supplemented with 10% FCS and 1% glutamine. Interleukin-6-dependent human myeloma cell lines XG1 were kind gifts from Prof. Zhang XG of Soochow University.

Primary MSCs were obtained from MM pa- 
tients after informed consent was obtained, ac-

cord with the guidelines of the ethics committee of Soochow University Hospital. Four heparinized BM aspirates were collected from MM patients and the bone marrow mononuclear cells (BMNCs) were separated by Ficoll-Hypaque density gra-

dient centrifugation. To purify the MSCs from BMNCs and remove hematopoietic stem cells, CD45+ cells were depleted by negative immuno-

magnetic cell selection using the Mini MACs de-

vice (Miltenyi Biotec, Germany) according to the manufacturer’s instructions. Samples obtained before and after depletion of the CD45+ cells were analyzed by flow cytometry (FCM). The resultant CD45-depleted BMNCs were cultured as described previously [16] and the cells were used as Cx43 positive controls.

RNA extraction and PCR assays

RNA expression of Cx43 of 4 MSCs isolated from MM patients and MM cell lines was carried out using standard RT-PCR techniques as previously described [16]. The primers of the Cx43 were used as follows: Cx43 (BC026329) F:ATGAGCAGTGCTGCCTTTCGT and R:TCTGCTTCAAGTGCATGTCC. Cells were washed 2–4 times with PBS prior to RNA isolation. Briefly, total RNA was extracted using the RNeasy mini kit (Qiagen, Germany); downstream of Soochow University.

RNA extraction and PCR assays

RNA expression of Cx43 of 4 MSCs isolated from MM patients and MM cell lines was carried out using standard RT-PCR techniques as previously described [16]. The primers of the Cx43 were used as follows: Cx43 (BC026329) F:ATGAGCAGTGCTGCCTTTCGT and R:TCTGCTTCAAGTGCATGTCC. Cells were washed 2–4 times with PBS prior to RNA isolation. Briefly, total RNA was extracted using the RNeasy mini kit (Qiagen, Germany) and contaminating genomic DNA was removed by treatment with RNase-free DNase I (Qiagen, Germany). The PCR was optimized by 1.5 mmol/l MgCl2 and a final extension of 10 min at 72°C in a thermocycler (Eppendorf, Hamburg, Germany); β-actin served as an internal control.

Construction of Cx43-NT lentiviral vectors

Molecular cloning was done by Shanghai NovaBio Inc. China. DNA construct coding for amino acids 1-231 of the amino terminus of human Cx43 (Cx43NT-GFP) construction and verifying the over-expression of Cx43-NT in HUVEC cells were carried out using standard techniques as previously described [17, 18]. Briefly, for expression in HUVEC
cells, a full length cDNA of amplified human Cx43 WT cDNA was cloned into a pCDNA3.1 vector (Invitrogen, USA) using a designed oligonucleotide primer pair, 5’-ATGAAGCTTATGGATGGGAGC-GCTG-3’ and 5’-ATGGCGGCCGCTTAAGTTGGAAGGAGGCCTGTGAT-3’, to generate 5’ HindIII (aagctt) and 3’ NotI (gcggccgc) restriction sites for inframe ligation. The oligonucleotide primer pair was designed to preferentially amplify the Cx43-NT from the genomic DNA for the HUVEC cell line, which was: CX-NT-R; ACTGCTGGAGGGAAGGTG; CX-NT-F; TGAGTGTACACGGAAAG; pl/to/v5/GFP/ires/MCS-CX43-NT-R was generated with connection of the CX43-NT-GFP sequence and lentiviral vectors respectively the collected virus supernatant was infected with HUVEC cells, transfection efficiency of Cx43-NT overexpressing cells which was observed by fluorescence microscopy and qpcr. All constructs were confirmed by sequencing.

Cell culture, selection and characterization of Cx43-NT overexpressing cells

The HUVEC cell line (ATCC, Manassas, VA, USA) was maintained in Dulbecco’s modified minimal essential medium (DMEM, Life Technologies, Inc., Burlington, ON, USA) supplemented with 10% (v/v) fetal bovine serum (Life Technologies, Inc.), at 37°C, in a humidified atmosphere containing 95% air and 5% CO2. These cells were used throughout this study. For transfections, the cells were split the day prior to transfection to reach 70–80% confluence. Stable HUVEC cell transfectants expressing Cx43-NT were generated by transfection, respectively with a CX43-NT cDNA encoding plasmid using the Lipofectamine kit (Invitrogen Corporation, California, USA) and subsequent selection for G418 resistance according to the manufacturer’s instructions. Transfectants were tested by qpcr for Cx43-NT expression.

GJIC between the HUVEC and myeloma cells

The myeloma cell line RPMI8266 cells were simultaneously labeled with 10 μM calcein-AM (Invitrogen, USA) and 10 μM 1,1’-dioctadecyl-3,3,3’,3’-tetramethylindo-carbocyanine perchlorate (DiI, Invitrogen, USA) for 25 min at 37°C in a 5% CO2, fully humidified atmosphere. Cells were washed twice in PBS prior to being dropped onto receiving cells (MSCs and HUVEC Cx43-NT) or without heptanol (50 mM/l). A total of 2 × 104 resulting cells were seeded to the precultured MSCs and HUVECCx43-NT cells and the culture was incubated for 75 min at 37°C. To block the GJIC, heptanol was dissolved in ethanol as described previously [19, 20], so that the final concentration in the cell culture medium equaled 0.15% ethanol with 50 and 100 mM heptanol.

Prior to conducting FACS studies, the cultures were examined microscopically to confirm transfer of dye from myeloma cells to MSCs or HUVEC Cx43-NT. For FACS analysis studies, cells were trypsinized to release MSCs and HUVEC Cx43-NT, fixed in 4% paraformaldehyde, and resuspended in FACS buffer, and then FACS analyzed on a Facstar Plus Flow Cytometer (Becton Dickinson, USA).

Co-culture of HUVEC with myeloma cell

To test the effects of Cx43 coupling on survival of MM cells, RPMI8266 and XG1 cells were plated to 6-well plates at a concentration of 5 × 103/well alone or with MSCs and HUVEC Cx43-NT in medium with or without 2 × 10–7 M/l dexamethasone. The cultures were continued for 48 h and cell numbers, viability (trypan blue assay) and annexin V/PI binding were determined by flow cytometry. In the meantime, co-culture of RPMI8266 and XG1 MM cells with MSCs and HUVEC Cx43-NT in medium containing 2 × 10–7 M dexamethasone and 50 mM/ml heptanol was also done in the same conditions.

Transwell migration assay

We performed a transwell migration assay (Co-star) using the MM cell line RPMI 8226 in the presence of MSCs or HUVEC Cx43-NT cells, which were cultured in the lower chambers. Seven groups were included in the assay: (1) control, upper chamber: MM cells, lower chamber: DMEM-LG supplemented with 0.5% FBS; (2) MSCs; upper chamber: MM cells, lower chamber: MSCs; (3) MSCs + heptanol; upper chamber: MM cells, lower chamber: MSCs + heptanol; (4) HUVEC Cx43-NT; upper chamber: MM cells, lower chamber: HUVEC Cx43-NT; (5) HUVEC Cx43-NT + heptanol; upper chamber: MM cells, lower chamber: HUVEC Cx43-NT + heptanol. In brief, MM cells were suspended in 0.5% FBS medium, and 5 × 102 cells were placed in the upper chambers of the transwell plates with or without MSCs or HUVEC Cx43-NT cells in the lower chambers. The concentration of heptanol used in these experiments was 50 mM/l. After 4 h at 37°C, cells that migrated to the lower chambers were counted. Triplicate experiments were performed with each group, and the means and standard deviations were calculated.

Cytokine production

The supernatants from RPMI8266 cells alone or with MSCs and HUVEC Cx43-NT in medium with or without heptanol (50 mM/l) were collected. The IL-6, IL-10, transforming growth factor β (TGF-β), and SDF-1α concentrations were measured by Cytometric Bead Array (CBA) assay, using kits obtained from BD Biosciences Pharmingen.
(USA) according to the manufacturer’s recommendations.

Western blotting

RPMI8266 cells alone or with MSCs and HUVEC<sup>Cx43-NT</sup> in medium with or without heptanol (50 mM/l) from direct co-culture systems were collected according to the methods mentioned above. Total cell lysates for Western blots were prepared by lysing cell pellets in radioimmunoprecipitation assay (RIPA) buffer. Bicinchoninic acid was used to determine protein concentrations. The lysates were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE; Bio-Rad, USA), and transferred to polyvinylidene difluoride membranes, which were subsequently blocked in Tris-buffered saline containing 5% non-fat milk and 0.1% Tween for 1 h. The membranes were then incubated with polyclonal rabbit anti-p-Cx43 hSer368, ERK1/2, JNK, p38, NF<sub>κB</sub> (the antibodies were bought from Cell Signaling Technology) and anti-glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (Sigma) at 4°C overnight. Antigen-antibody complexes were detected using secondary antibodies conjugated to horseradish peroxidase (Invitrogen) and visualized by enhanced chemiluminescence (GE Healthcare, UK).

Statistical analysis

Statistical analyses of data were performed using the Statistical Package for the Social Sciences (SPSS) software version 17.0 (SPSS Inc., Chicago, IL, USA). Differences were evaluated by Student’s t test and nonparametric Mann-Whitney test (significance cutoff: p < 0.05).

Results

Cx43 expressed differently among the MM cell lines and primary MM cells

The expression of Cx43 on MM cell lines RPMI 8226 and XG1 and the MSCs isolated from MM patients (n = 4) was determined using PCR assays. The results showed that both MM cells and MSCs expressed Cx43, although the expression of Cx43 in those cells was at different levels (Figure 1 A). Western blot analysis revealed that RPMI 8226 and XG1 cells expressed Cx43 at moderate levels. All four primary MSCs from MM patients expressed Cx43 (Figure 1 B). Generally, Cx43 expression in MSCs was stronger than that in MM cells (p < 0.05).

GJIC between MM cells and HUVEC are functional

Transfectants were confirmed by QPCR for Cx43-NT expression (Figure 2). To clarify the role of Cx43 on MM cells, we employed Cx43-NT truncated Cx43 to overexpress on HUVEC cells and MSCs isolated from MM patients as positive controls.

To determine whether MM cells couple with HUVECs, MM cells, MSCs and HUVEC<sup>Cx43-NT</sup> cells were cocultured and examined microscopically to confirm transfer of dye from MM cells to MSCs or HUVEC<sup>Cx43-NT</sup> cells, although there was much less dye transferred to HUVEC<sup>Cx43-NT</sup> as comparison to MSCs. Visual inspection confirmed the viability of both the donor and receptor cells and demonstrated that the dye transfer was specific. FACS analysis was used to show the transfer of calcein AM to MSCs and HUVEC<sup>Cx43-NT</sup> (Figure 3), demonstrating that MM-HUVEC GJIC occurs.

Because our data showed that MM can couple with MSCs and HUVEC<sup>Cx43-NT</sup> cells, we wanted to confirm that the GJIC was specific. This was accomplished by using the GJ blocking agent. Heptanol was titrated into HUVEC cultures and then the cultures were analyzed by FACS analysis as above. Our results demonstrated that inhibition of dye transfer from MM to MSCs or HUVEC<sup>Cx43-NT</sup> occurred in a dose-dependent manner.

Coupling with MSCs/HUVEC<sup>Cx43-NT</sup> protected MM cells from apoptosis in presence of dexamethasone

RPMI 8266 and XG1 MM cells were incubated alone or cultured with MSCs and HUVEC<sup>Cx43-NT</sup> for 48 h in medium with or without dexamethasone. The total number of myeloma cells recovered from cultures of myeloma cells alone was significantly lower than that from co-cultures, and their viability was also significantly lower (p < 0.01), while their apoptotic rate was significantly higher than that of myeloma cells cultured with MSCs and HUVEC<sup>Cx43-NT</sup> (p < 0.01) (Figure 4). Both MSCs and

![Figure 1. Cx43 expression on MM cells and MSCs. The RT-PCT assays showed that either MM cell lines or primary MSCs isolated from MM patients expressed Cx43 (A). Western blot assay showed that MSCs expressed higher levels of Cx43 than those of MM cells (B)](image)
Impact of connexin 43 coupling on survival and migration of multiple myeloma cells

HUVEC<sub>Cx43-NT</sub> could partially rescue the MM cells from apoptosis in the co-culture conditions. It seemed that MSCs were more effective to protect MM cells from apoptosis in medium containing dexamethasone and that XG1 cells was more sensitive to dexamethasone-induced cell death. Our results demonstrated that the GJs have an impact on the survival of MM cells and more MM cells were apoptotic in the medium containing the GJ inhibitor heptanol.

**GJ blockage by heptanol inhibited migration of MM cells induced by MSCs**

In transwell migration assays, the migration rate of MM cell lines (RPMI 8226, XG-1) toward MSCs HUVEC<sub>Cx43-N</sub> was higher than that of spontaneous migration (<i>p</i> < 0.05), which indicated that both MSCs and HUVEC<sub>Cx43-NT</sub> could induce the migration of MM cells. The migration of MM cells toward MSCs was the highest among the 5 groups (<i>p</i> < 0.05). The process was partially inhibited by the GJ inhibitor heptanol (Figure 5). These results show that heptanol can inhibit the migration of MM cells induced by MSCs or endothelial cells (HUVEC) and indicate that GJs may play important roles in the process of chemotaxis induced by MSCs and HUVEC cells.

Cx43 coupling changes the cytokine profile of MSCs

CBA assays revealed high levels of IL-6 in supernatant of MSCs cultured alone, but the others...
Figure 3. Gap junctions among the MM, MSCs and HUVECs. Microscopic photographs from the double labeling of MM cells with calcein-AM (green) and Dil (red) show that dye transfer occurs from myeloma cells to MSCs and HUVECs (3-1/3-2) and that dye does not permeate from the cells stained with Dil (3-1.1/3-2.1), confirming that GJIC is functional between the two cells, and that the dye transfer was specific. FCM histograms (A, B) of RPMI 8266 after dual-labeled MM were administered onto MSCs in a parachute assay, with GJs allowed to form. FCM data show the percentage of MSCs into which calcein-AM was transferred from MM cells and was inhibited in the presence of heptanol (50 mM/l).
Figure 4. Coupling with MSCs/HUVEC Cx43-NT protects MM cells from apoptosis in the presence of dexamethasone. RPMI 8266/XG1 cells were cultured in medium containing 2 × 10⁻⁷ M/l for 48 h and the apoptosis of MM cells was determined by FCM analysis. The rate of apoptosis of MM cells cultured in the absence of MSCs was approximately 84%/79.8%, but the ratio percentage of apoptosis decreased significantly when MM cells were co-cultured with MSCs ($p < 0.01$), and increased when treated with 50 mM/l heptanol compared with the controls. HUVEC Cx43-NT partially reversed the MM cells from apoptosis when the MM cells were co-cultured with HUVEC Cx43-NT under the same conditions, although they were less effective than in the case of MSCs.

A1, B1 – RPMI 8226 or XG1 cultured alone; A2, B2 – RPMI 8226 or XG1 + dexamethasone; A3, B3 – RPMI 8226 or XG1 + MSCs + dexamethasone; A4, B4 – RPMI 8226 or XG1 + MSCs + dexamethasone + heptanol; A5, B5 – RPMI 8226 + HUVEC Cx43-NT + dexamethasone; A6, B6 – RPMI 8226+ HUVEC Cx43-NT + dexamethasone + heptanol
were at low levels, and there was no IL-10 detected in the supernatant. The cytokines detected in the supernatant of RPMI 8266 cultured alone was also at a low level. The concentration of cytokines detected in supernatant of HUVEC Cx43-NT was low in comparison with MSCs, but higher than that of RPMI 8226. The level of IL-6, IL-10 and SDF-1α increased significantly after MSC and MM cells were co-cultured for 24 h ($p < 0.01$), and especially the levels of IL-6 and IL-10 were higher in comparison to those cells cultured alone ($p < 0.001$). There was no change of the level of TGF-β before and after co-culture. After blockage of the GJIC with heptanol, the levels of IL-6 and SDF-1α returned to normal, but the level of IL-10 was higher than in those cells cultured alone ($p < 0.01$). The same results were also obtained from RPMI 8226 cells co-cultured with HUVEC Cx43-NT. The levels of cytokines were lower than those of MSCs ($p < 0.05$) (Figure 6).

**GJ between MM cells and stromal cells involved in JNK and NF-κB signaling**

In this study, in order to explore further the molecular mechanisms of Cx43 signaling in the...
MM, we investigated the changes of signaling pathways within our cell model during the Cx43 coupling in the presence and absence of the Cx43 specific inhibitor heptanol. As shown in Figure 7, the protein levels of phosphorylated Cx43 were increased in MSCs after co-culture and pCx43 decreased significantly in the presence of the GJ inhibitor. However, the pCx43 expression of HUVEC\textsuperscript{Cx43-NT} showed no marked changes whether in co-culture with MM cells or in the presence of heptanol. To understand whether the MAPK intracellular signaling molecules might be involved in the C-terminus of Cx43 in mediating the transduction of cell survival signals and thereby exerting anti-proliferative effect on MM cells, we investigated the change of MAPK pathways by Western blot assay in our cell models. We found that the expression of p38, JNK and NFK\textsubscript{B} increased, and especially the expression of p38 and JNK was significantly increased in co-culture, while it had no effect on the expression of ERK1/2. Our study showed that Cx43 coupling promotes MM cell survival via activation of p38, JNK and its downstream signal pathway.

**Discussion**

GJIC has been implicated in the regulation of homeostasis and a diverse array of cellular func-
tions related to cell specialization, growth and differentiatiation [21]. Altered expression of connexins, such as reduced expression or aberrant localization, has been reported in many tumor tissues [22–25]. Such alterations prevent cell-to-cell adhesion, which is indispensable for the formation of gap junctions. In consequence, a clone of cells selectively acquires the ability for fast and unrestricted growth along with disruption of tissue integrity. Recent evidence further suggests that connexins may even facilitate late stage disease progression and metastasis [26]. Although connexins seem to be linked to tumorigenesis in the breast [21, 27, 28], the current understanding of how these molecules are linked to cancer is relatively limited, as few studies have systematically examined the role of connexins in both early and late stages of disease progression in a unified model.

The results of many studies indicate that the microenvironment created by MSCs plays an important role in supporting myeloma cells. Although it has been shown that myeloma stromal cells contribute to mature myeloma cell growth and chemoresistance, little is known about the GJ interplay between MSCs [29, 30]. We have previously demonstrated that Cx43 was expressed heterogeneously and aberrantly in MM cells. Interestingly, Cx43 expression in MSCs isolated from patients with MM was greater than that observed in both MM cells and normal MSCs [31]. To determine biochemically the function of the Cx43 protein within the cells and elucidate the role of Cx43 in gap junction formation, this study cloned and expressed the N-terminal part of Cx43 in HUVEC cells. The studies reported herein showed that both MM cell lines and MSCs isolated from MM patients express Cx43 at mRNA and protein levels, and GJ formed between those cells was functional. MM cells also coupled with MSCs cultured alone. This was also in agreement with observations showing that connexins expression may be present in later stages of carcinogenesis, favoring the migration capacity of invasive cells [35]. The Cx43 without the C-terminal lost the function of enhancing the migration of MM cells and the GJ inhibitor had no effects on the migration of MM cells. Although there seemed to be more cells counted in the lower chamber, the difference was not statistically significant.

Though the transmembrane part and the extracellular loops are highly conserved among the different connexin isoforms, the carboxyl terminus is the most variable in length and amino acid sequence. The carboxyl terminus of several connexins contains various phosphorylation sites which play an important role in regulating GJ channel conductivity and function. Recently, a channel-independent role for connexins in intracellular signaling was suggested. Plotkin et al.
[36–38] demonstrated a novel function of the C-terminus of Cx43 in mediating the transduction of cell survival signals induced by the anti-osteoporosis drugs bisphosphonates in osteoblasts and osteocytes. Their studies showed that bisphosphonates open Cx43 hemichannels and induce the interaction of Cx43 with the kinase Src, followed by activation of the ERK pathway and inhibition of osteoblast and osteocyte apoptosis. This evidence raises the possibility that a similar scaffolding function of Cx43 could be required for the survival effect of MM cells. Our results demonstrated that the protein levels of phosphorylated Cx43 were increased in MSCs after co-culture with MM cells and pCx43 decreased significantly in the presence of a GJ inhibitor (Figure 7). However, the pCx43 expression of HUVEC Cx43-NT showed no presence of a GJ inhibitor. We conjectured that the protein levels of phosphorylated Cx43 could be required for the survival effect of MM cells. Our results demonstrated that the protein levels of phosphorylated Cx43 were increased in MSCs after co-culture with MM cells and pCx43 decreased significantly in the presence of a GJ inhibitor (Figure 7). However, the pCx43 expression of HUVEC Cx43-NT showed no marked changes whether in co-culture with MM cells or in the presence of heptanol. To understand the MAPK intracellular signaling molecules which might be involved in the C-terminus of Cx43 in mediating the transduction of cell survival signals so as to exert an anti-apoptotic effect on MM cells, we investigated the change of MAPK pathway associated molecules by western blot assay in our cell models. We found that the expression of p38, JNK and NfκB increased, and especially the expression of p38 and JNK was significantly increased in co-culture, while it had no effect on the expression of ERK1/2, and the up-regulated p38 and JNK expression was not inhibited in the presence of the GJ inhibitor. We conjectured that the adhesion of MM cells to MSCs may be involved apart from GJ in the crosstalk between them. Behrens et al. [39] demonstrated that expression of Cx43 augmented migration via modulation of p38 MAP kinase activity. The carboxyl tail of Cx43 plays an essential role in this signaling pathway, which is independent of gap junction function. Our study was consistent with theirs and confirmed that Cx43 coupling promoted MM cell survival via activation of p38, JNK and its downstream signal pathway. Recently, Belting et al. [40, 41] demonstrated the potential role of nanotubes, exosomes, apoptotic bodies, and nucleic acid-binding peptides in the intercellular transfer of genetic information and indicated that various facets of cell biology research will revolutionize the way we perceive how cells communicate as well as the way we treat various diseases. In that respect, a better understanding of the interaction of the MM cells with bone marrow cells would provide insight into a wide array of pathophysiologicals and whether this opens avenues for therapeutic intervention.
