Equations of motion in gravity theories with nonminimal coupling: A loophole to
detect torsion macroscopically?

We derive multipolar equations of motion for gravitational theories with general nonminimal
coupling in spacetimes admitting torsion. Our very general findings allow for the systematic testing
of whole classes of theories by means of extended test bodies. One peculiar feature of certain
subclasses of nonminimal theories turns out to be their sensitivity to post-Riemannian spacetime
structures even in experiments without microstructured test matter.

Keywords: Equations of motion; Conservation laws; Approximation methods

I. INTRODUCTION

In a recent work [1] we derived the conservation laws for the most general class of nonminimally coupled gravity
theories. Here we are going to work out the equations of motion for this whole class of theories by using Synge’s
expansion technique [2] in combination with a multipolar framework à la Dixon [3]. The framework does not only
cover the metric case, but it is also general enough to cope with theories which go beyond the usual Riemannian
framework [4]. In particular it allows for a generalized discussion of microstructured media.

The results obtained here extend the ones in [5–13]. In particular, they offer a new perspective on placing possi-
bile observational constraints on new geometric features like torsion.

Our notations and conventions are those of [4]. In particular, the basic geometrical quantities such as the curva-
ture, torsion, etc., are defined as in [4], and we use the Latin alphabet to label the spacetime coordinate indices. Furthermore, the metric has the signature (+, −, −, −).

The structure of the paper is as follows: In section I we briefly discuss the class of theories under consideration.
In particular we provide the conservation laws, which in turn are crucial for the subsequent derivation of the mul-
tipolar equations of motion in section III. Apart from providing the general form of these equations, we study the
pole-dipole equations of motion in detail, and thereby find an analogue to the classical Mathisson-Papapetrou
[14, 15] equations for the whole class of nonminimal coupling theories under consideration. Furthermore, we dis-
cuss the case of test matter without microstructure and its peculiar type of coupling to post-Riemannian spacetime
features. Our final conclusions and an outlook on open problems is given in section IV. Appendices A and B contain
a brief overview of our conventions and some frequently used formulas.

II. GENERAL NONMINIMAL GRAVITY

In order to be as general as possible, we consider matter with microstructure, namely, with spin. An appropri-
ate gravitational model is then the Poincaré gauge theory in which the metric tensor $g_{ij}$ is accompanied by the
connection $\Gamma_{kij}$, that is metric-compatible but not necessarily symmetric. The gravitational field strengths are
the Riemann-Cartan curvature and the torsion:

$$ R_{kij} = \partial_k \Gamma_{lij} - \partial_l \Gamma_{kij} + \Gamma_{kn}^j \Gamma_{li}^n - \Gamma_{ln}^j \Gamma_{ki}^n , \quad (1) $$

$$ T_{ki} = \Gamma_{kl}^i - \Gamma_{lk}^i . \quad (2) $$

In [1], we worked out the conservation laws for a general nonminimal gravity model in which the interaction
Lagrangian reads

$$ L_{\text{int}} = F(g_{ij}, R_{kij}, T_{ki}) L_{\text{mat}} . \quad (3) $$

The coupling function $F(g_{ij}, R_{kij}, T_{ki})$ depends arbitrarily on its arguments. In technical terms, $F$ is a function
of independent scalar invariants constructed in all possible ways from the components of the curvature and
torsion tensors. The matter Lagrangian has the usual form $L_{\text{mat}} = L_{\text{mat}}(\psi^A, \nabla \psi^A, g_{ij})$.

A Lagrange-Noether analysis, see [4], yields the following conservations laws:

$$ F \Sigma_k^i = F t_k^i + \nabla_n (F r_k^i n^k) , \quad (4) $$

$$ \nabla_i (F \Sigma_k^i) = F \Sigma_k^i T_{ki} - F r_m^k R_{kln} - L_{\text{mat}} \nabla_k F . \quad (5) $$

Here we made use of the following abbreviations, i.e.

$$ \Sigma_k^i = \frac{\partial L_{\text{mat}}}{\partial \psi^A} \nabla_k \psi^A - \delta_k^i L_{\text{mat}} , \quad (6) $$

* dirk.puetzfeld@zarm.uni-bremen.de  http://puetzfeld.org
obukhov@ihep.ac.ru
for the canonical energy-momentum tensor,

$$\tau_{ki}^n = -\frac{\partial L_{\text{mat}}}{\partial \psi^A} (\sigma^A \beta)_k^n \psi^B,$$

(7)

for the canonical spin tensor, and

$$t_{ij} = \frac{2}{\sqrt{-g}} \left( \sqrt{-g} \right) \frac{\partial (\sqrt{-g} L_{\text{mat}})}{\partial g^{ij}}.$$

(8)

for the metrical energy-momentum tensor. Furthermore, we made use of the so-called modified covariant derivative, which is defined as usual by

$$\nabla_i = \nabla_i - T_{ki}^k.$$

(9)

Lowering the index in (4) and antisymmetrizing, we derive the conservation law for the spin

$$F \Sigma_{[ij]} + \nabla_n (F \Sigma_{[ij]}^n) = 0.$$

(10)

This is a generalization of the usual conservation law of the total angular momentum for the case of nonminimal coupling.

### A. Purely Riemannian theory

Our results contain the Riemannian theory as a special case. Suppose the torsion is absent $T_{ij}^k = 0$. Then for usual matter without microstructure (spinless matter with $\tau_{ki}^n = 0$) the canonical and the metrical energy-momentum tensors coincide, $\Sigma_{k}^i = t_{k}^i$. As a result, the conservation law (6) reduces to

$$\nabla_i t_{k}^i = \frac{1}{F} (-L_{\text{mat}} \delta_k^i - t_k^i) \nabla_i F.$$

(11)

### B. Further generalization: Matter with intrinsic moments

Our formalism allows one to consider also the case when matter couples to the gravitational field strengths not just through an $F$-factor in front of the Lagrangian but directly via Pauli-type interaction terms in $L_{\text{mat}}$:

$$I^{kmn}_{ijkl} (\psi^A, g_{ij}) R_{klm}^n + J_{ijkl}^n (\psi^A, g_{ij}) T_{klm}^n.$$

(12)

In Maxwell’s electrodynamics similar terms describe the interaction of the electromagnetic field to the anomalous magnetic and/or electric dipole moments. For Dirac spinor matter [16, 17] the Pauli-type quantities $I^{kmn}_{ijkl} (\psi^A, g_{ij})$ and $J_{ijkl}^n (\psi^A, g_{ij})$ are interpreted as the (Lorentz and translational, respectively) “gravitational moments” that arise from the Gordon decomposition of the dynamical currents.

The on-shell conservation laws are then given by:

$$\Sigma_{k}^i = t_{k}^i + \nabla_n (\tau_{ki}^n) - 2J_{ij}^n T_{kln}^+ + J_{n}^i T_{klm}^n - 2 I^{lmn}_{ijkl} R_{klm}^n - 2 I^{lmn}_{ijkl} R_{[lmn]k},$$

(13)

$$\nabla_i \Sigma_{k}^i = \nabla_i (\tau_{ki}^n) - \nabla^m \nabla_i R_{kln}^m - J_{ijkl}^n \nabla_i T_{klm}.$$  

(14)

The skew-symmetric part of (13) describes the generalized conservation of the angular momentum:

$$\nabla_n \tau_{[ik]}^n = -\Sigma_{[ik]} + J_{ln}^i T_{kln}^+ + 2 I_{[i}^l m R_{k]lnm} + 2 I^{lmn}_{ijkl} R_{[lmn]k}.$$  

(15)

For the Riemann-Cartan curvature tensor the pairs of indices do not commute, $R_{ijkl} \neq R_{klji}$, and one cannot reduce the two terms in the second line of (15).

However, in the purely Riemannian case of General Relativity, the torsion vanishes and the curvature tensor has more symmetries (in particular, the pairs of indices do commute). Then the system (14) and (15) reduces to the familiar Mathisson-Papapetrou form

$$\nabla_n \tau_{[ik]}^n = -\Sigma_{[ik]} + 4 I_{[i}^l m R_{k]lnm},$$

(16)

$$\nabla_i \Sigma_{k}^i = -\tau_{ki}^n R_{kln}^m - I^{lmn}_{ijkl} \nabla_i R_{[lmn]}.$$  

(17)

The symmetric part of equation (16) describes the relation between the metrical and canonical energy-momentum tensors. When deriving (16), we took into account that in view of the contraction in (12), we have the symmetry properties

$$I_{ijkl} = I_{[ijkl]} = I_{ij [kl]} = I^{kl ij}.$$  

(18)

The form of the system of conservation laws (16)–(17) is very close to Dixon’s equations describing the dynamics of material body with the dipole and quadrupole moments. However, it is important to stress that in contrast to Dixon’s integrated moments of usual structureless matter, $\tau_{[ik]}^n$ and $I^{lmn}_{ijkl}$ are the intrinsic spin and quadrupole moments of matter with microstructure. The above conservation laws can also be viewed as a direct generalization of the ones for spinning particles and polarized media given in [18].

It is worthwhile to note that in the Riemann-Cartan spacetime the conservation laws (14) and (15) contain two types of intrinsic quadrupole moments. We identify $I_{ijkl}$ with the rotational (Lorentz) quadrupole moment, whereas $J_{ijkl}^n$ is naturally interpreted as the translational quadrupole moment. These quantities are coupled to the corresponding rotational and translational gravitational field strengths, i.e., to the curvature $R_{ijkl}$ and the torsion $T_{klm}$, respectively.

### III. Equations of motion

The conservation equations (1) and (2) form the basis for a general multipolar analysis. In the following we are
going to derive the equations of motion for test bodies by utilizing the expansion technique of Synge [2]. Since we are now working in a spacetime which allows for more structure, we now also have – apart from the metric \(g_{ab}\) – the torsion \(T_{ab}\). This leads to an additional degree of freedom regarding the transport operations in the underlying multipolar formalism. We can proceed in two ways: (i) extend Synge’s technique to non-Riemannian spacetimes – thereby switching to a new type of (non-geodesic) reference curve; or (ii) use the standard Riemannian approach and treat torsion as an additional variable. Here we follow the latter strategy.

### A. Rewriting conservation laws

The Riemann-Cartan connection can be decomposed into the Riemannian (Christoffel) connection

\[
\tilde{\Gamma}^k_{ij} = \Gamma^k_{ij} = \frac{1}{2} g^{kl} (\partial_i g_{jl} + \partial_j g_{il} - \partial_l g_{ij}),
\]

plus the post-Riemannian piece:

\[
\Gamma^k_{ij} = \tilde{\Gamma}^k_{ij} - K^k_{ij}.
\]

Here the contortion tensor reads

\[
K^k_{ij} = -\frac{1}{2} (T^k_{ij} - T^k_{ji} + T^k_{ij}) = -K^k_{ij}.
\]

We use the hat to denote objects and operators (such as the curvature, covariant derivatives, etc) defined by the Riemannian connection [19].

Using the decomposition (20), we rewrite the conservation laws (19) as

\[
\tilde{\nabla}_n (F T_{[ik]}^n) = F (K^l_{ni} T_{[kl]}^n - K^l_{nk} T_{[il]}^n) - F \Sigma_{[ik]},
\]

\[
\tilde{\nabla}_i (F \Sigma_{k}^{ij}) = - F \Sigma_{[ik]} K^l_{ki} - F \tau^m_{n} R_{klm}^n - L_{\text{mat}} \nabla_k F.
\]

We can develop the usual Riemannian-worldfunction based multipole expansion starting from (22) and (23).

Defining auxiliary variables like in [13], i.e.

\[A(g_{ij}, R_{ij}^k, T_{ij}^k) := \log F, A_i := \nabla_ia, A_{ij} := \nabla_j a_i \text{ etc.,}
\]

we rewrite (22) and (23) as follows:

\[
\tilde{\nabla}_n T_{[ik]}^n = K^l_{ni} T_{[kl]}^n - K^l_{nk} T_{[il]}^n - \Sigma_{[ik]},
\]

\[
\tilde{\nabla}_i \Sigma_k^i = - \Sigma_{[ik]} K^l_{ki} - \tau^m_{n} R_{klm}^n - A^i \Xi_{ik},
\]

\[
A_{ij} := g_{ij} L_{\text{mat}}.
\]

### B. Multipolar approximation

We will now derive the equations of motion of a test body by utilizing the covariant expansion method of Synge [2]. For this we need the following auxiliary formula for the absolute derivative of the integral of an arbitrary bitensor density \(B^{x_1 \cdots x_n} = B^{x_1 \cdots x_n}(x, y)\) (the latter is a tensorial function of two spacetime points):

\[
\frac{D}{ds} \int \frac{B^{x_1 \cdots x_n}}{\Sigma(s)} d\Sigma_{x_1} = \int \frac{\nabla_{x_1}}{\Sigma(s)} B^{x_1 \cdots x_n} w_{x_1} d\Sigma_{x_2}
\]

\[
+ \int \frac{B^{x_2 \cdots x_n}}{\Sigma(s)} d\Sigma_{x_1}.
\]

Here \(w := dx/y, ds = s, \) is the proper time, \(\frac{D}{ds} = \nu \frac{\partial}{\partial t},\) and the integral is performed over a spatial hypersurface. Note that in our notation the point to which the index of a bitensor belongs can be directly read from the index itself; e.g., \(y_n\) denotes indices at the point \(y\). Furthermore, we will now associate the point \(y\) with the world-line of the test body under consideration. Denote

\[
\Phi^{y_1 \cdots y_n y_0 x_0} := \sigma^{y_1 \cdots y_n y_0 x_0},
\]

\[
\Psi^{y_1 \cdots y_n y_0 y', x_0 x'} := \sigma^{y_1 \cdots y_n y_0 x_0 g^{y'y'}}.
\]

We start by integrating (24) and (25) using (26):

\[
\frac{D}{ds} \int \Phi^{y_1 \cdots y_n y_0 x_0} \sum_{x_2} \frac{1}{\nu(x_2)} d\Sigma_{x_2} =
\]

\[
\int \left[ K^l_{x_1 x_2} \sum_{x_3} \frac{1}{\nu(x_3)} \right] w_{x_2} d\Sigma_{x_2}
\]

\[
+ \int \left[ K^l_{x_1 x_2} \sum_{x_3} \frac{1}{\nu(x_3)} \right] w_{x_2} d\Sigma_{x_2}
\]

\[
+ \int \Phi^{y_1 \cdots y_n y_0 x_0 x'} \sum_{x_2} \frac{1}{\nu(x_2)} w_{x_2} d\Sigma_{x_2},
\]

\[
\frac{D}{ds} \int \Phi^{y_1 \cdots y_n y_0 x_0} \sum_{x_2} \frac{1}{\nu(x_2)} d\Sigma_{x_2} =
\]

\[
\int \left[ K^l_{x_1 x_2} \sum_{x_3} \frac{1}{\nu(x_3)} \right] w_{x_2} d\Sigma_{x_2}
\]

\[
+ \int \Phi^{y_1 \cdots y_n y_0 x_0 x'} \sum_{x_2} \frac{1}{\nu(x_2)} w_{x_2} d\Sigma_{x_2}
\]

\[
+ \int \Phi^{y_1 \cdots y_n y_0 x_0 y_0 + 1} \sum_{x_2} \frac{1}{\nu(x_2)} w_{x_2} d\Sigma_{x_2}.
\]

Here the derivatives are straightforwardly evaluated:

\[
\Phi^{y_1 \cdots y_n y_0 y', x_0 x'} = \sum_{a=1}^{n} \sigma^{y_1 \cdots y_n y_0 g^{y'y'}}
\]

\[
+ \sigma^{y_1 \cdots y_n} \left( g^{y'y'} x_0 g^{y'y'} + g^{y'y'} x_0 g^{y'y'} \right),
\]

\[
\Phi^{y_1 \cdots y_n y_0 y_0 x_0} = \sum_{a=1}^{n} \sigma^{y_1 \cdots y_n y_0 g^{y'y'}}
\]

\[
+ \sigma^{y_1 \cdots y_n} g^{y'y'} x_0 z,
\]

where \(z\) stands either for \(x\) or \(y\).

We now introduce integrated moments à la Dixon in [3], i.e.
we infer from (24) that the canonical energy-momentum tensor in view of (4). Furthermore, we have as a starting point for the derivation in the first term with the symmetric $y^x y^2 d\Sigma_{x_2}$,

$$
\xi y^2 \cdots y^9 y^1 := (-1)^n \int_{\Sigma(s)} \Phi y^1 \cdots y^n \frac{\partial}{\partial y} \Sigma_{x_1} \frac{\partial}{\partial y} d\Sigma_{x_1},
$$  

(33)

$$
\zeta y^2 \cdots y^9 y^1 := (-1)^n \int_{\Sigma(s)} \Phi y^2 \cdots y^{10} y^1 \frac{\partial}{\partial y} \Sigma_{x_2} \frac{\partial}{\partial y} d\Sigma_{x_2},
$$  

(34)

$$
\phi y^2 \cdots y^9 y^1 := (-1)^n \int_{\Sigma(s)} \Phi y^2 \cdots y^{10} y^1 \frac{\partial}{\partial y} \Sigma_{x_3} \frac{\partial}{\partial y} d\Sigma_{x_3},
$$  

(35)

$$
q y^2 \cdots y^9 y^2 := (-1)^n \int_{\Sigma(s)} \Phi y^3 \cdots y^2 y^2 \frac{\partial}{\partial y} \Sigma_{x_3} \frac{\partial}{\partial y} d\Sigma_{x_3}.
$$  

(36)

Then (29) and (30) take the form

$$
\frac{D}{ds} s y^1 \cdots y_n y_b = \left( -t y^1 \cdots y_n [y_a y_b] + q(y_1 \cdots y_n - 1) [y_a y_b] + q(y_1 \cdots y_n + 1) [y_a y_b] \right) + \left( v^{y'} y^1 \cdots y_n + 1 [y_a y_b] + q y_1 \cdots y_n [y_a y_b] \frac{\partial}{\partial y} y^1 \cdots y_n + 1 \right) \frac{\partial}{\partial y} y^1 \cdots y_n + 1 - 2 q y_1 \cdots y_n + 1 [y_a y_b] K y^1 \cdots y_n + 1 y_b
$$  

(37)

$$
\frac{D}{ds} p y^1 \cdots y_n y_0 = v(y_1 \cdots y_n + 1) y_0 + t(y_1 \cdots y_n - 1) y_0 [y_a y_b] + K y_0 y^1 \cdots y_n - 1 y'_b + K y_0 y^1 \cdots y_n + 1 y'_b y'_b + \frac{1}{2} K y^1 \cdots y_n + 1 y'_b y'_b + K y^1 \cdots y_n - 1 y'_b y'_b - 2 q y_1 \cdots y_n + 1 [y_a y_b] K y^1 \cdots y_n + 1 y_b
$$  

(38)

$$
A y^1 \cdots y_n y_0 = \left( v y^1 \cdots y_n + 1 [y_a y_b] + q y_1 \cdots y_n [y_a y_b] \frac{\partial}{\partial y} y^1 \cdots y_n + 1 \right) \frac{\partial}{\partial y} y^1 \cdots y_n + 1 - 2 q y_1 \cdots y_n + 1 [y_a y_b] K y^1 \cdots y_n + 1 y_b
$$  

C. Vanishing spin current

For the special case of vanishing spin current $\tau^{abc} = 0$, we infer from (24) that the canonical energy-momentum tensor is symmetric $\Sigma_{ij} = 0$, and that it coincides with the metrical energy-momentum tensor in view of (4). Furthermore, we have as a starting point for the derivation of the equations of motion

$$
\nabla_i \Sigma^{k i} = -K^{k}_{i} \Sigma^{l i} - A_i \left( \Sigma^{i k} + \Sigma^{k i} \right).
$$  

(40)

Due to the antisymmetry of the contortion, the contraction in the first term with the symmetric $t$ moment – in the case of an absent spin current – vanishes identically. Hence we are left with structurally the same equation as in (13), the only difference being that here $A(\Sigma_{ij}, R_{ijk}^l, T_{ij}^k)$ is a function of the curvature $\Sigma$ and the torsion.

For the vanishing spin all the corresponding multipole moments $\mathcal{Q}_{ij}$ and $\mathcal{P}_{ij}$ vanish, too: $\mathcal{Q}_{ij} = 0$ and $\mathcal{P}_{ij} = 0$.

1 Note the different sign of $\Sigma$ in this paper; this is explained by a different definition of the metrical energy-momentum tensor as compared to [13].
and \(q^{b_3 \cdots b_{n+1} 0 y_1 y_2} = 0\) for any \(n\). In addition, the multipole moments \(t^{0y_2 \cdots y_{n+1} 0 y_1 y_2}\) are symmetric in the last two indices.

1. Monopole order \((\tau_{ab}^c = 0)\)

At the monopole order we have
\[
\frac{D}{ds} p^a = -A_b (\xi_{ab} + t_{ab}),
\]
\[
t_{ab} = p^a v^b.
\]
Substituting (42) into (41), we recover the equation of motion
\[
\frac{D}{ds} (Fp^a) = -\xi_{ab} v^b F.
\]
As we see, the nonminimal coupling is manifest in the nongeodetic motion of the monopole test particle.

2. Pole-dipole order without spin \((\tau_{ab}^c = 0)\)

At the pole-dipole order we obtain
\[
\frac{D}{ds} p_{ab} = t^{[ab]} - \epsilon^{[ab]} p_b - A_c (\xi_{abc} + t_{abc}),
\]
\[
\frac{D}{ds} p^a = -\frac{1}{2} \hat{R}^a_{bcd} (v^c p^d + t^{dcb}) - A_b (\xi_{ab} + t_{ab}),
\]
\[
- A_{bc} (\xi_{cab} + t_{cab}).
\]
Note that we did not make any simplifying assumptions about the spacetime which still has the general Riemann-Cartan geometric structure with nontrivial torsion. Nevertheless, neither torsion nor contortion contributes to the equations of motion (45) and (46).

D. General pole-dipole equations of motion

Let us consider the general case when the extended body consists of material elements with microstructure, i.e., with spin. In the pole-dipole approximation, the relevant moments are \(p^{a}, p_{ab}, t^{a}_{ab}, t^{abc}, \xi^{abc}, s^{abc}, q^{abc}\), and we neglect all higher multipole moments. Then for \(n = 1\) and \(n = 0\), eq. (38) yields
\[
0 = -t_{[ab]} + q^{[abc]} - \epsilon^{[abc]} s_{bc},
\]
\[
\frac{D}{ds} s_{ab} = -t_{[ab]} - 2q^{[a][d]} K_{d bc} - q^{abc} A_c,
\]
whereas (39) for \(n = 2, n = 1,\) and \(n = 0\) yields
\[
0 = -v^{(a} p^{bc) + t^{[a][b]}},
\]
\[
\frac{D}{ds} p^a = -v^a p^b + t^{ba} + K^a_{cd} t^{acd},
\]
\[
- A_c (\xi_{abc} + t_{abc}),
\]
\[
\frac{D}{ds} p_{ab} = K^a_{cd} t^{cd} + K^a_{cd} t^{bcd} - \frac{1}{2} \hat{R}^a_{bcd} (v^c p^d + t^{dcb}) - A_b (\xi_{ab} + t_{ab}) - A_{bc} (\xi_{cab} + t_{cab}).
\]
Combining (47) with (49), we derive
\[
t^{[a][b]} = v^a p^{[ab]} + v^{[a][b]} - \xi^{[a][b]} + t^{[a][b]},
\]
\[
= v^a p^{[ab]} + v^{[a][b]} + 2t^{[a][b]} - 3t^{[a][b]}.\]
Furthermore, we can substitute (47) into (52) and thus express \(t^{[a][b]}\) in terms of the \(p\), \(q\), and \(s\)-moments:
\[
t^{[a][b]} = v^c(p^a - s^a) + v^d(p^b - s^b) + q^{abc} + 2q^{[abc]}.
\]
Antisymmetrizing (50), we find
\[
\frac{D}{ds} p^{[ab]} = -v^a s^b + v^b s^a + K^b_{cd} t^{[ac]d},
\]
\[
- A_c (\xi^{[a][b]} + t^{[a][b]}).
\]
Combining this equation with (48), we eliminate \(t^{[ab]}\) and using (47) derive
\[
\frac{D}{ds} (p^{[ab]} - s^{[ab]}) = -v^a (p^b + K^b_{cd} s^{cd})
\]
\[
+ 2q^{[a][b]} K^c_{dc} + 2q^{[a][d]} K_{dc}^b
\]
\[
+ A_c (q^{abc} - \xi^{[a][b]} - t^{[a][b]}).
\]
Next, substituting (47), (48), and (53) into (51), we obtain after some algebra
\[
\frac{D}{ds} p^a + K^a_{cd} s^{cd} = \hat{R}^a_{bcd} (p^d - s^d) v^b
\]
\[
+ q^{[d][b]} K_{d bc} - 2K^a_{dn} K_{b ec} - K^a_{cd} A_b
\]
\[
- A_{bc} (\xi_{cab} + t_{cab} - \xi_{cab} + t_{cab}).
\]
We now introduce the integrated orbital angular momentum and the integrated spin angular momentum of an extended body as
\[
L^{ab} := 2p^{[ab]}, \quad S^{ab} := -2s^{[ab]},
\]
respectively.

Then, after a straightforward but rather lengthy computation, we can recast (59) and (57) into the final form
\[
\hat{D} \mathcal{J}^{ab} = -2v^a s^b + 2FQ^d [a T_{cd}^b] + 4FQ^d [a T_{cd}^b] c d
\]
\[
- (4q^{[a][b]} + 2q^{[a][b]} + 2s^{[a][b]} - \xi^{[a][b]} + t^{[a][b]}) \nabla_e F,
\]
\[
\hat{D} \mathcal{P}^a = \frac{1}{2} \hat{R}^a_{bcd} \mathcal{J}^d v^b + FQ^d c d \hat{D} v^b T_{bc}^d
\]
\[
- 2q^{[d][b]} K_{d bac} - \xi_{bac} F + 2FQ^d c d \hat{D} A_e
\]
\[
- \xi_{bac} F - \xi_{bac} \nabla_b F.
\]
Here we defined the total energy-momentum vector and the total angular momentum tensor by

\[ \mathcal{P}^a := F \left( p^a - \frac{1}{2} K_{cd}^a S^{cd} \right) + \left( p^{ab} - S^{ab} \right) \nabla_b F, \]

\[ \mathcal{J}^{ab} := F \left( L^{ab} + S^{ab} \right). \]

In addition, we introduced a redefined moment

\[ Q^{bca} := \frac{1}{2} \left( q^{bca} + q^{bca} - q^{ca} \right). \]

By construction, \( q^{bca} = -q^{abc} \). In the derivation of (59) and (60) we made use of (17), (54) and took into account the geometrical identity

\[ R^a_{bcd} - R^b_{abcd} \equiv K_{abcd}^a + K_{cd}^a b + 2 K_{bca}^a K_{dca}^b. \]

The latter can be proved by substituting the decomposition of the Riemann-Cartan connection (20) into the curvature definition (1). Furthermore, it is helpful to notice that

\[ q^a c[a, b, c, d] \equiv q^{a[cd} T_{b]cd} + 2 Q^{a [cd} T_{b]cd} + 2 Q_{[cd} T_{b]cd} \]

and

\[ q^{ab} K_{bca}^a \equiv q^{ab} K_{bca}^a. \]

The equations of motion (59) and (60) generalize the results obtained in [13] to the case when extended bodies are built of matter with microstructure and move in a Riemann-Cartan spacetime with nontrivial torsion.

1. Minimal coupling

When the coupling function is constant, \( F = 1 \), that is for the minimal coupling case, we obtain

\[ \mathcal{P}^a = p^a - \frac{1}{2} K_{cd}^a S^{cd}, \quad \mathcal{J}^{ab} = L^{ab} + S^{ab}, \]

and the equations of motion

\[ \frac{D}{ds} \mathcal{J}^{ab} = -2 \mathcal{P}^{a[b} b + 2 Q^{[a} c [d] T_{b]cd} + 4 Q^{a} c [d] T_{b]cd}, \]

\[ \frac{D}{ds} \mathcal{P}^a = \frac{1}{2} \tilde{R}^a_{bca} \mathcal{J}^{bc} + q^{bca} \tilde{S}^{ab} T_{bc} \]

Comparing these equations to the conservation laws (11) and (12), it is remarkable that the redefined dipole spin moment (63) actually took over the role of the translational quadrupole moment. That is, up to a factor \((-2\), conventionally introduced in [38], we can identify \( Q^{bca} \) with \( J^{bca} \). This interesting feature was not reported before.

2. Nonminimal coupling: a loophole to detect torsion?

It is satisfying to see that the structure of the equations of motion (60)–(67) is in agreement with the earlier results of Yasskin and Stoeger [6]. Therefore, we confirm once again that spacetime torsion couples only to the integrated spin \( S^{ab} \), which arises from the intrinsic spin of matter, and the higher moment \( q^{abc} \). Hence, usual matter without microstructure cannot detect torsion and, in particular, experiments with macroscopically rotating bodies such as gyroscopes in the Gravity Probe B mission do not place any limits on torsion [19].

However, this conclusion is apparently violated for the nonminimal coupling case. As we see from (60) and (61), test bodies of structureless matter could be affected by torsion via the derivatives of the coupling function \( F(g_{ij}, R_{ijkl}, T_{kli}) \). On the other hand, this possibility is qualitatively different from the ad hoc assumption that structureless particles move along auto-parallel curves in the Riemann-Cartan spacetime made in [20–22]; see the critical assessment in [19]. The trajectory of a monopole particle, described by (13), is neither geodesic nor auto-parallel. The same is true for the dipole case when the nonminimal coupling force is combined with the Mathisson-Papapetrou force.

IV. CONCLUSION

We have obtained equations of motion for material bodies with microstructure, thus generalizing the previous works [5, 6, 8, 18] to the general framework with nonminimal coupling. The master equations (38) and (39) describe the dynamics of an extended body up to an arbitrary multipole order. It turns out that, despite a rather complicated general structure of the equations of motion, most of the terms in (38) and (39) show up only at the quadrupole order or higher orders.

In the special case of minimal coupling (which is recovered when \( F = 1 \)), our results can be viewed as the covariant generalization of the ones in [5, 6], as well as the parts concerning Poincaré gauge theory of [5].

A somewhat surprising result in the present nonminimal context with torsion, is the – indirect – appearance of the torsion through the coupling function \( F \) even in the lowest order equations of motion for matter without intrinsic spin – see eqs. (11)–(12). This clearly is a distinctive feature of theories which exhibit nonminimal coupling, which sets them apart from other gauge theoretical approaches to gravity. As we have shown in [6, 8, 9], and as it is also discussed at length in the recent review [19], in the minimally coupled case only microstructured matter couples to the post-Riemannian spacetime features – in particular, in the minimally coupled case one needs matter with intrinsic spin to detect the possible torsion of spacetime. As we have shown in the current work, this is no longer the case in the nonminimally coupled context. In other words, supposing that one can come up with a sensible background model for spacetime including torsion, it could be somewhat constrained through standard test bodies – i.e. made from regular matter – through the derived equations of motion, in particular through (11)–(12) in the monopolar case.

Despite the progress made here, we would also like to
point out some open questions and directions for future investigations. (i) In a post-Riemannian context, there is naturally more freedom regarding the possible geometry of spacetime. This additional freedom could also be used for an extension and modification of the multipolar framework itself in general spacetimes encompassing, besides the curvature, also new quantities like torsion. In particular, one could carry out the derivations in the present work with a modified world-function formalism, i.e. one which is no longer based on the geodesic structure of the spacetime – see also [23–25] for some generalizations in this direction. While such a modification remains a possibility, which is somewhat linked to the discussion of which types of curves are “natural” in specific spacetimes, one should also be clear that one would lose comparability with almost all of the previous works on equations of motion. (ii) Another generalization concerns the generalization to the metric-affine case, i.e. in including, apart from the torsion, also the nonmetricity of spacetime. The results in this paper already hint into this direction. In general non-Riemannian spacetimes, one can expect a direct coupling term, not only through the function $F$, on the level of the equations of motion. This will eventually lead to more “fine grained” possible tests of post-Riemannian geometric structures.

Appendix A: Conventions & Symbols

In the following we summarize our conventions, and collect some frequently used formulas. A directory of symbols used throughout the text can be found in table I.

For an arbitrary $k$-tensor $T_{a_1...a_k}$, the symmetrization and antisymmetrization are defined by

$$T_{(a_1...a_k)} := \frac{1}{k!} \sum_{l=1}^{k!} T_{a_1...a_k},$$

(A1)

$$T_{[a_1...a_k]} := \frac{1}{k!} \sum_{l=1}^{k!} (-1)^{|\pi|} T_{a_{\pi(1)}...a_{\pi(k)}}$$

(A2)

where the sum is taken over all possible permutations (symbolically denoted by $\pi_{(a_1...a_k)}$) of its $k$ indices. As is well-known, the number of such permutations is equal to $k!$. The sign factor depends on whether a permutation is even ($|\pi| = 0$) or odd ($|\pi| = 1$). The number of independent components of the totally symmetric tensor $T_{(a_1...a_k)}$ of rank $k$ in $n$ dimensions is equal to the binomial coefficient $\binom{n-1+k}{k} = (n-1+k)!(k!(n-1)!)$, whereas

| Symbol | Explanation |
|--------|-------------|
| $g_{ab}$ | Metric |
| $\sqrt{-g}$ | Determinant of the metric |
| $\delta^a_b$ | Kronecker symbol |
| $x^a$, $s$ | Coordinates, proper time |
| $\Gamma^c_{ab}$ | Connection |
| $K_{abc}$ | Contortion |
| $T_{ab}$ | Torsion |
| $R_{abc}$ | Curvature |
| $\sigma$ | World-function |
| $g^{\mu\nu}$ | Parallel propagator |

### Geometrical quantities

| Symbol | Explanation |
|--------|-------------|
| $\psi^a$ | General matter field |
| $\Sigma^a_b$ | Canonical energy-momentum |
| $t^a_b$ | Metrical energy-momentum |
| $\pi^a_{bc}$ | Canonical spin |
| $t^{abcd}$, $s^{abc}$ | Pauli-type moments |
| $v^a$ | Velocity |
| $\mathcal{P}^a$ | Generalized momentum |
| $S^{ab}$ | Spin angular momentum |
| $L^{ab}$ | Orbital angular momentum |
| $J^{ab}$ | Total angular momentum |
| $L$ | Lagrangian |
| $p^{y_1...y_n}$, $p^{y_1...y_n+1}$ | Integrated moments |
| $q^{y_1...y_n}$, $q^{y_1...y_n+1}$ | Integrated moments |

### Matter quantities

| Symbol | Explanation |
|--------|-------------|
| $\alpha^{y_1...y_n}$, $\beta^{y_1...y_n}$, $\gamma^{y_1...y_n}$ | Expansion coefficients |

### Auxiliary quantities

| Symbol | Explanation |
|--------|-------------|
| $\nabla_a$ | Modified cov. derivative |
| $F$, $A$ | Coupling function |
| $\alpha^{y_1...y_n}$, $\beta^{y_1...y_n}$, $\gamma^{y_1...y_n}$ | Expansion coefficients |

| Operators | Explanation |
|-----------|-------------|
| $\partial_i$ | (Partial, covariant) derivative |
| $\nabla_i$ | Total derivative |
| $\alpha_{\ldots n}$ | Coincidence limit |
| $\beta_{\ldots n}$ | Riemannian quantity |

The number of independent components of the totally antisymmetric tensor $T_{[a_1...a_k]}$ of rank $k$ in $n$ dimensions is equal to the binomial coefficient $\binom{n}{k} = n!/[k!(n-k)!]$. For example, for a second rank tensor $T_{ab}$, the symmetrization yields a tensor $T_{(ab)} = \frac{1}{2}(T_{ab} + T_{ba})$ with 10 independent components, and the antisymmetrization yields another tensor $T_{[ab]} = \frac{1}{2}(T_{ab} - T_{ba})$ with 6 independent components.
The covariant derivative defined by the Riemannian connection \( \nabla_a \) is conventionally denoted by the nabla or by the semicolon: \( \nabla_a = \partial_a \).

Our conventions for the Riemann curvature are as follows:

\[
2A^{c_1 \ldots c_k} d_{i_1} \ldots d_{i_l} = 2\nabla_{[a} \nabla_{b]} A^{c_1 \ldots c_k} d_{i_1} \ldots d_{i_l}
\]

\[
= \sum_{i=1}^{k} \hat{R}_{abe} c_i A^{c_1 \ldots c_k} d_{i_1} \ldots d_{i_l}
- \sum_{j=1}^{l} \hat{R}_{abc} d_j A^{c_1 \ldots c_k} d_{i_1} \ldots d_{i_l}.
\]

\( \hat{R} \) is determined at \( y \). Furthermore, we collect the following useful identities:

\[
\sigma_{y_0 y_1 y_2 y_3} = \sigma_{y_0 y_1 y_2 x_0 x_1} = \sigma_{x_0 x_1 y_0 y_1 y_2}, \quad (A6)
\]

\[
g^{x_1 x_2} \sigma_{x_1 x_2} = 2\sigma = g^{y_1 y_2} \sigma_{y_1 y_2}, \quad (A7)
\]

\[
[\sigma] = 0, \quad [\sigma_x] = [\sigma_y] = 0, \quad (A8)
\]

\[
[\sigma_{x_1 x_2}] = [\sigma_{y_1 y_2}] = g_{y_1 y_2}, \quad (A9)
\]

\[
[\sigma_{x_1 y_1 y_2}] = [\sigma_{x_1 y_2}] = -g_{y_1 y_2}, \quad (A10)
\]

\[
[\sigma_{x_1 x_2 y_3}] = [\sigma_{x_1 y_2 y_3}] = [\sigma_{y_1 y_2 y_3}] = 0, \quad (A11)
\]

\[
[g^{x_0 y_1}] = \delta^{y_0 y_1}, \quad [g^{x_0 y_1 ; x_2}] = [g^{x_0 y_1 ; y_2}] = 0. \quad (A12)
\]

Appendix B: Covariant expansions

Here we briefly summarize the covariant expansions of the second derivative of the world-function, and the derivative of the parallel propagator:

\[
\sigma_{y_0 x_1} = g^{y_0 y_1} \left(-\delta^{y_0 y_1} + \sum_{k=2}^{\infty} \frac{1}{k!} \gamma^{y_0 y_{y_2} \ldots y_k}, \sigma_{y_2} \ldots \sigma_{y_{k+1}} \right), \quad (B1)
\]

\[
\sigma_{y_0 y_1} = \delta^{y_0 y_1} - \sum_{k=2}^{\infty} \frac{1}{k!} \beta^{y_0 y_{y_2} \ldots y_{k+1}}, \sigma_{y_2} \ldots \sigma_{y_{k+1}}, \quad (B2)
\]

\[
g^{x_0 x_1 ; x_2} = g^{y_0 y_1} \gamma^{y_0 y_{y_2} \ldots y_{k+1}}, \sigma_{y_2} \ldots \sigma_{y_{k+1}} \right), \quad (B3)
\]

\[
g^{x_0 x_1 ; y_2} = g^{y_0 y_1} \left(1 - \frac{1}{2} R^{y_0 y_2 y_3} \right) \sigma_{y_3} \right) + \sum_{k=2}^{\infty} \frac{1}{k!} \gamma^{y_0 y_{y_2} \ldots y_{k+1}} \sigma_{y_3} \ldots \sigma_{y_{k+1}}, \quad (B4)
\]

The coefficients \( \alpha, \beta, \gamma \) in these expansions are polynomials constructed from the Riemann curvature tensor and its covariant derivatives. The first coefficients read as follows:

\[
\alpha^{y_0 y_1 y_2 y_3} = -\frac{1}{3} \hat{R}^{y_0 y_2 y_3} y_{y_1,}, \quad (B5)
\]

\[
\beta^{y_0 y_1 y_2 y_3} = \frac{2}{3} \hat{R}^{y_0 y_2 y_3} y_{y_1,}, \quad (B6)
\]

\[
\alpha^{y_0 y_1 y_2 y_3} y_{y_4,} = -\frac{1}{3} \hat{\nabla}_{y_2} \hat{R}^{y_0 y_2 y_3} y_{y_4,}, \quad (B7)
\]

\[
\beta^{y_0 y_1 y_2 y_3} y_{y_4,} = \frac{1}{3} \hat{\nabla}_{y_2} \hat{R}^{y_0 y_2 y_3} y_{y_4,}, \quad (B8)
\]

\[
\gamma^{y_0 y_1 y_2 y_3} y_{y_4,} = \frac{1}{3} \hat{\nabla}_{y_2} \hat{R}^{y_0 y_2 y_3} y_{y_4}, \quad (B9)
\]

In addition, we also need the covariant expansion of a usual vector:

\[
A_z = \hat{g}^{y_0 x} \sum_{k=0}^{\infty} \frac{(-1)^k}{k!} A_{y_0 ; y_1 \ldots y_k} \sigma_{y_1} \ldots \sigma_{y_k}. \quad (B10)
\]
