Background: Curcumin and vanillin are the two useful compounds in food and medicine. Bismuth nitrate pentahydrate is an economical and ecofriendly reagent.

Method: Bismuth nitrate pentahydrate impregnated montmorillonite KSF clay and curcumin were subjected to microwave irradiation.

Results: Microwave-induced bismuth nitrate-promoted synthesis of vanillin from curcumin has been accomplished in good yield under solvent-free condition. Twenty-five different reaction conditions have been studied to optimize the process.

Conclusion: The present procedure for the synthesis of vanillin may find useful application in the area of industrial process development.

Keywords: Curcumin, Vanillin, Microwave, Bismuth nitrate, Fragrance

Background

Curcumin, a polyphenol derived from Curcuma longa (commonly known as turmeric) is an ancient spice and therapeutic used in India for centuries to induce color in food and to treat a wide array of diseases. It has been demonstrated that curcumin has many beneficial pharmacological effects, including anti-inflammatory [1], antioxidant [2], antiviral [3], antiangiogenic [4] effects. Most importantly, curcumin possesses immense antitumorigenic effect. It prevents tumor formation in a number of animal models, including models of skin, colon, liver, esophageal, stomach, and breast cancer [5-8]. Curcumin has also demonstrated the ability to improve patient outcomes in Phase I clinical trials [9]. The potential application of curcumin as a chemopreventive agent in both animal and human studies has been demonstrated [10]. Very recently, curcumin has been reported [11] as a protectant against neurodegenerative diseases through chelation with iron. On the other hand, vanillin (4-hydroxy-3-methoxybenzaldehyde) is an important guaiacol derivative which is extremely selective inhibitor of aldehyde oxidase. It has been found that it acts as a substrate of this enzyme, and is metabolized by aldehyde dehydrogenase [12]. Because of the exceptionally widespread utilization of vanillin in the food, cosmetic, pharmaceutical, nutraceutical and fine chemical industries makes this compound as one of the most important aromas. As a result of these crucial properties, considerable attention has been devoted to the improvement of the production processes of vanillin [13]. We report herein an easy and extremely rapid one-step method for the preparation of vanillin from naturally occurring curcumin in the presence of bismuth nitrate under microwave irradiation (Figure 1).

Methods

FT-IR spectra were registered on a Bruker IFS 55 Equinox FTIR spectrophotometer as KBr discs. ¹H NMR (300 MHz) and ¹³C NMR (75 MHz) spectra were obtained at room temperature with JEOL-300 equipment using d₆-DMSO as solvent. Analytical grade chemicals (Sigma-Aldrich Corporation, Milwaukee, USA) were used throughout the project. Deionized water was used for the preparation of all aqueous solutions.
Results and discussion

In continuation of our research on environmentally benign reactions, we have been working on methodology development using microwave irradiation for many years. Using microwave irradiation technique, we have successfully developed several new organic methodologies which include stereoselective synthesis of β-lactams [14–16], synthesis of pyrroles [17–20], aza-Michael addition [21], and synthesis of quinoxalines [22]. On the other hand, we have demonstrated the catalytic activity of trivalent bismuth nitrate pentahydrate in a number of occasions. These experiments resulted in various methods that include nitration of aromatic systems [23–25], Michael reaction [26], protection of carbonyl compounds [27], deprotection of oximes and hydrazones [28], Paal-Knorr synthesis of pyrroles [29], hydrolysis of amide [30], electrophilic substitution of indoles [31,32], synthesis of α-aminophosphonates [33], and Biginelli condensation [34]. Our success in the bismuth nitrate-induced reaction has confirmed that this reagent acts as a Lewis acid. Bismuth nitrate pentahydrate is proved to be an effective reagent for the preparation of vanillin. However, Zn(NO₃)₂, Ca(NO₃)₂, LaNO₃, NaNO₃, ceric ammonium nitrate, and Cu(NO₃)₂ were also studied but without any success. Dry conditions and solvent-free methods along with commercial solvents without any purification were investigated in order to identify the best conditions for this reaction (Table 1). Reactions were performed at high temperature using Dean-Stark water separator, traditional reflux, and conventional kitchen microwave-induced methods. Solid surfaces such as florisil, silica gel, molecular sieves, montmorillonite KSF clay, and neutral alumina were used as solid support in the reaction. It has been found that montmorillonite KSF clay is the best solid surface (entries 4, 9, and 19) among all others.

Experimental

Curcumin (1 mmol), bismuth nitrate pentahydrate (0.75 equivalent), and solid support (500 mg) were mixed in dichloromethane (4 mL) and the solvent was evaporated by rotavapor. The mixture was irradiated in kitchen microwave and the reaction was monitored by TLC. After completion of the reaction (Table 1), the reaction mixture was extracted with dichloromethane and basified with saturated aqueous sodium bicarbonate solution. The organic layer was then washed with brine and

Conclusions
In summary, a new and simple method for the synthesis of vanillin from naturally occurring curcumin has suc-
cessfully been investigated. Trivalent bismuth nitrate-
induced synthesis of vanillin has successfully been carried 
out under various conditions and the formation of a sin-
gle product (4-hydroxy-3-methoxybenzaldehyde) has 
been observed in variable yields. The exploratory results 
described herein confirm that bismuth nitrate pentahy-
drate is the reagent of choice for the oxidative cleavage of 
curcumin to vanillin in the absence of any solvent under 
microwave-irradiation condition (entry 19). Importantly, 
no aromatic nitration and rearrangement of curcumin or 
vanillin has been observed with bismuth nitrate. A selec-
tive oxidation of the alkene bond of curcumin to vanillin 
has taken place. Considering the structure of vanillin and 
the conditions of the experiments, one can expect further 
oxidation of the aromatic aldehyde group or nitration of 
the aromatic system might be other possibilities. How-
ever, it is interesting to note that such reactions although 
feasible, but vanillin is the only isolated product. On the 
basis of these important and selective observations, this 
method will find very useful applications in industrial 
chemistry.
