Abstract

Background: Neural stem cells are multipotent cells which are capable of self-replication and differentiation into neurons, astrocytes or oligodendrocytes in the central nervous system. Therefore, one can expect that NSC transplantation can ultimately provide a better therapeutic approach in the treatment of neurodegeneration, like Parkinson's Disease (PD).

Aim: In order to use the therapeutic potential of neural stem cells, it is essential to fully understand the cellular and molecular mechanisms involved in the function of Dopamine secretion by the cells.

Methods: We assayed the growth potential and DOPAmine production of hNSCs in presence of neurotropic factors. Release of neurotropic factors by hNSCs also determined by ELISA.

Results: We found that hNSCs can secrete DOPAmine as well as some neurotropic factors, like Brain-Derived Neurotropic Factor (BDNF) and Glial cell-Derived Neurotropic Factors (GDNF). These factors can further support the proliferation of hNSCS and DOPAmine production ability of the neural cells.

Conclusion: That way, an Autocrine-Paracrine regulatory system have been established in the neural cells.

Introduction

Parkinson's disease (PD) is characterized by the progressive loss of dopaminergic neurons in the substantia nigra pars compacta (SNc) [1-3]. Specific neurotrophic factors that are secreted from neighboring cells, like GDNF, a glial cell line-derived neurotrophic factor [4], and BDNF, a brain-derived neurotrophic factor [5,6], are well known for their role in growth, survival, and differentiation of developing neurons [7-9]. These factors also have been found to attenuate the loss of nigrostriatal dopaminergic neurons in animal models of Parkinson’s Disease (PD), and also interfere with both apoptotic and necrotic forms of cell death and promotes the survival of dopaminergic neurons in culture [4,10].

Here we show that hNSCs can produce BDNF and GDNF along with DOPAmine, and those neurotropic factors can stimulate the proliferation of hNSCs in vitro. Further, these neurotropic factors can increase DOPAmine secretion by hNSCs. DOPAmine itself, can also induce the secretion of those neurotropic factors by neural cells, thereby established an autocrine-paracrine loop for dopaminergic function of hNSCs.

Materials and methods

1) Culture of hNSCs (Human Neural Stem Cells): hNSCs (H9) derived from adult normal human of female origin were purchased from ThermoFisher (Rockford, IL, USA). The growth and maintenance of undifferentiated hNSCs were conducted with human neural stem cell growth medium supplemented with human neural stem cell growth factors (GS2) and antibiotics (GS1) from Cell Applications (San Diego, CA, USA). In brief, hNSCs were cultured in 6-well tissue culture plates pre-coated with cell-matrix gel (ATCC, Manassas, VA) containing 5 ml complete growth medium at 37°C in a 5% CO2 humidified incubation chamber.

Sub-culturing and passaging of the hNSC spheres were done by Accutase, a cell dissociation reagent, (ATCC, Manassas, VA), into single cells. Single cells (1A ~ 106) were then plated in the 6-well tissues culture plates coated with Matrix gel (ATCC, Manassas, VA) in 4 ml complete culture medium.

2) Proliferation assay by Cell-Glo Luminiscence reagent: Proliferation of cells was detected using the Cell-Titer-Glo Luminescent Cell Viability Assay kit (Promega, Madison, WI). For in vitro growth assays, cells (1x103/ well) were plated in 96- well plates and on the next day ‘0 day’ reading followed by every alternate day cell growth was measured using the Cell-Titer-Glo-kit until for 6 days. Luminescence was read using the BioTek plate reader [11]. Results were expressed as percentage of vehicle-control cells. Results presented are Mean ± SD from three separate experiments done in triplicate.

3) Detection of BDNF and GDNF protein concentration by ELISA: Enzyme-linked immunosorbent assays (ELISA) was performed to detect BDNF, and GDNF secreted by hNSCs in the culture supernatant at different days and in different groups. Standard curve was made with the preparations of standard compounds (2000, 1000, 500, 250, 125, 62.5, 31.25, 15.625 pg/mL).

Key words: BDNF, DOPAmine, dopaminergic neurons, GDNF, parkinson's disease

Received: April 13, 2020; Accepted: April 20, 2020; Published: April 23, 2020
62.5, 31.3, and 0 pg/mL) in each of 50 µL volume. Standard solutions and test samples were added sequentially to the antibody pre-coated wells. Samples were thoroughly incubated at 37°C for 120 minutes. Wells were rinsed four times with wash buffer, and allowed to soak for 1 minute each time. The reaction plate was dried with filter paper. The biotinylated antibody working solution (50 µL/well) was added and plates were incubated for 60 minutes at 37°C. The wells were then washed four times with wash buffer. Enzyme-labeled antibody (rabbit anti-human NGF polyclonal antibody; BG, Shanghai, China) working solution (50 µL/well) was added and incubated for 30 minutes at 37°C. Wells were washed. Subsequently, 3,3', 5,5'-tetrathyl benzidine solution (50 µL/well) was added for 15 minutes at 37°C in the dark. The reaction was terminated by the addition of 3,3', 5,5'-tetrathyl benzidine stopping solution (50 µL/well).

Absorbance values were measured at 450 nm with a microplate reader (Labsystems, Helsinki, Finland). The mean absorbance value for each standard sample was calculated. The mean value of the zero standard was subtracted from all absorbance values before result interpretation. The standard curve was generated by plotting the average absorbance value obtained for each of the eight standard concentrations on the vertical (Y) axis the corresponding concentration on the horizontal (X) axis. This standard curve was used to determine the concentration of the unknown sample.

4) DOPamine level by ELISA: Dopamine release was quantified using ELISA kits (Eagle Bioscience, Nashua, NH; Cat# DOP31-K01). All samples were stabilized immediately with orthophosphoric acid (7.5%)/metabisulfate (0.22 mg/mL) and stored at −80°C before analysis. Dopamine extraction, acylation, and enzyme immunoassay were performed according to the manufacturers’ instructions. Every sample and standard was performed in duplicate. Absorbance was read using a microplate reader set to 450 nm and a reference wavelength set between 620 and 650 nm. Data were from three independent experiments.

5) Protein determinations: Protein content was measured using the Bio-Rad Protein Assay Kit (Bio-Rad, Richmond, CA) with bovine serum albumin as the standard.

6) Cell counting: Cell count and viability measurements were done by staining the cells with Trypan Blue and then counting the number of viable cells with the Countess™ automated cell counter (Invitrogen).

7) Statistical analysis: The t-test and one-way analysis of variance were used for statistically analyzing the data. All values are expressed as the mean ± SD. P values < 0.05 were considered significant. Results are representative of at least three experiments.

Results

1) Production of BDNF or GDNF by hNSCs in culture (Table 1): The levels of BDNF or GDNF were assayed in the hNSC cell lysates by ELISA, and the values were expressed as ng/10⁵ Cells for BDNF, while GDNF was expressed as pg/10⁵ Cells. The experimental data are Mean ± SD from three separate experiments done in duplicate. P<0.05.

|          | BDNF | GDNF |
|----------|------|------|
| ng/10⁵ Cells |      |      |
| 0.43 ± 0.10 | 18.34 ± 2.12 |

The levels of BDNF or GDNF were assayed in the hNSC cell lysates by ELISA. BDNF level was expressed as ng/10⁵ Cells, while GDNF was expressed as pg/10⁵ Cells. The experimental data are Mean ± SD from three separate experiments. P<0.05.

2) Stimulation of BDNF and GDNF secretion by DA in hNSCs (Figure 1): The levels of BDNF or GDNF secretion in presence of DOPamine (DA) in culture were measured in the hNSC cell lysates by ELISA. The level of BDNF was expressed as ng/10⁵ Cells, while GDNF was expressed as pg/10⁵ Cells. The experimental data are Mean ± SD from three separate experiments done in duplicate. P<0.05. It is obvious from the results that both the neurotrophic factors (BDNF and GDNF) can stimulate at their physiological doses the DOPamine production by hNSCs.

3) Auto-stimulation of BDNF and GDNF secretion in hNSCs (Figure 2): The levels of BDNF or GDNF, measured as above (Figure 1), were induced by BDNF and GDNF at their physiological doses (0.5 µg/mL). Effect of GDNF in this connection is much more higher than BDNF. Level of BDNF was expressed as ng/10⁵ Cells, while GDNF was expressed as pg/10⁵ Cells. The experimental data are Mean ± SD from three separate experiments done in duplicate. P<0.05.

4) Simulation of proliferation of hNSCs by BDNF and GDNF (Figure 3): Proliferation rate (as %) of hNSCs were stimulated by BDNF and GDNF at their sublethal doses (0.05 µg/mL) in a time dependent manner. The experimental doses of the neurotrophic factors were chosen from some preliminary experiments (not shown), and which is at par of the published data from elsewhere [12]. GDNF shows a little more efficacy over BDNF in stimulating the proliferation of hNSCs. The experimental results displayed here are from a representative experiment done in triplicate. Values are expressed as a Mean ± SD from triplicate data (P<0.05). This experiment was repeated three different times with similar results. The difference in values from experiment to experiment was less than 10%.

5) BDNF and GDNF stimulates DOPamine secretion by hNSCs (Figure 4): DOPamine (DA) was measured by ELISA as described in our previous paper [13]. The production of DA was further induced by BDNF and GDNF treatment of the cells at their physiological doses (0.05 µg/mL). The experimental data were taken from a representative experiment done in triplicate. DA Values (ng/10⁵ Cells) were expressed as a Mean ± SD (P<0.05). The difference in values from experiment to experiment was less than 10%.

Discussion

Brain-derived neurotrophic factor (BDNF) and glial cell line-derived neurotrophic factor (GDNF) are critical for the growth, survival, and differentiation of developing neurons [14]. These neurotrophic factors also play important roles in the survival and function of adult neurons, learning and memory, and synaptic plasticity [4]. The initial trophic characterization of GDNF was performed in midbrain dopaminergic neuronal cultures; and in this work, GDNF not only promoted DANs survival but also soma enlargement and neurite outgrowth [4].

GDNF promotes the expansion of dividing nestin-positive neural precursors and increases the neurosphere diameter; however, this latter increase may also be associated with an anti-apoptotic response, since Bel-2 expression is up-regulated and caspase-3 expression is down-regulated [15]. As shown in the study by Roussa and Krieglstein (2004) [16], GDNF does not increase TH expression in neospheres derived from the ventral midbrain, but increases the expression of Nurr1 and Pitx3, the latter of which is a transcriptional factor that is part of the regulatory complex that maintains the dopaminergic phenotype. More recently, Nurr1 was reported to induce the expression of the co-receptor for GDNF, c-Ret. Nurr1-expressing cells exposed to...
The levels of BDNF (Panel, A) and GDNF (Panel, B) secretion in presence of DOPAmine in culture were measured in the hNSC cell lysates by ELISA. BDNF level was expressed as ng/10^6 Cells, while GDNF was expressed as pg/10^6 Cells. The experimental data are Mean ±SD from three separate experiments done in duplicate. P<0.05. Inset is the Standard Curve of BDNF (Panel, A) and GDNF (Panel, B).

Figure 1. Stimulation of BDNF and GDNF Secretion by DA in hNSCs

The levels of BDNF or GDNF were measured as above (Fig. 1) and found that their amounts were induced by BDNF and GDNF at their physiological doses (0.5 mg/mL). Effect of GDNF in this connection is much higher than BDNF. Level of BDNF was expressed as ng/10^5 Cells, while GDNF was expressed as pg/10^5 Cells. The experimental data are Mean ±SD from three separate experiments done in duplicate. P<0.05.

Figure 2. Auto stimulation of BDNF and GDNF Secretion in hNSCs
GDNF are eventually more responsive to GDNF, contributing to the up-regulation of Pitx3 expression and subsequently consolidating the dopaminergic phenotype [17]. In parallel, GDNF also increases DA transporter (DAT) activity [18]. Microarrays have corroborated that GDNF signaling favors the expression of genes associated with DA biosynthesis and recapture, as well as calcineurin. Inhibitors of ERK1/2 prevented these effects [19]. Thus, GDNF participates in proliferation and the acquisition of a dopaminergic phenotype. The mechanism by which GDNF interacts with other factors to promote this phenotype is still not clear.

Treatment of a human mesencephalic cell line with GDNF significantly increased dopaminergic differentiation and Dlk1 expression; practically all TH+ neurons were positive for Dlk1 as well [20]. Thus, GDNF might direct the commitment of neurons towards specific phenotypes in addition to increasing neuronal survival.

**Figure 4. Stimulation of Dopamine Secretion by BDNF and GDNF**

DOPAmine (DA) was measured by ELISA as described in our previous paper (Chakraborty and Diwan, In press). The production of DA was further induced by BDNF and GDNF treatment of the cells at their physiological doses (0.05 mg/mL). The experimental data were taken from a representative experiment done in triplicate. DA values (ng/10^5 Cells) were expressed as a Mean± SD (P<0.05). The difference in values from experiment to experiment was less than 10%.
In neurons, the outgrowth of the dendritic tree occurs in parallel with electrophysiological maturation, which in turn facilitates DA release after potassium depolarization. A GDNF or BDNF treatment significantly increases DA release from ventral mesencephalic cultures [21]. GDNF enhances the quantal size of DA release in postnatal cultures [22]. Consistent with these findings, an injection of GDNF in the substantia nigra of adult rats increases DA release in vivo and promotes behavioral consequences such as an increase in spontaneous locomotor activity and higher velocity of movement [23]. Rolletschek, et al. (2001) showed that a cocktail including GDNF promotes the expression of the pro-dopaminergic gene Nurr1 in neural precursors [24]. Further, it was shown that Sertoli cells secrete GDNF, and GDNF-neutralizing antibodies block dopaminergic differentiation by 50% in them [25], indicating that GDNF contributes in DOPamine release. The addition of recombinant GDNF to differentiating human NPCs derived from ESCs promotes a higher level of dopaminergic differentiation after 21 days in culture.

GDNF signaling indisputably possesses potential therapeutic value for several pathologies, such as Parkinson’s disease or amyotrophic lateral sclerosis, among other diseases, where it has been tested using molecular and cellular approaches [26-28]. The understanding of the entire range of properties of GDNF and other trophic molecules, like BDNF, could provide opportunities to investigate their broad actions and accelerate and/or improve therapies based on these factors.

In summary, the hNSCs utilized in this study exhibited an intrinsic ability to express neurotrophins. During development GDNF and BDNF, along with neurotrophin-3 (NT3), support the survival of sensory neurons through their cognate trk receptors [29-31]. The BDNF-responsive, trkB-containing population of sensory neurons is predominantly larger diameter and mecano sensitive [32], although there is considerable overlap with the trkA population [33]. GDNF receptors are more wide-spread, with as many as 60% of dorsal root ganglion (DRG) neurons containing c-ret, while GFR components are found throughout the c-ret population, as well as in c-ret negative neurons [34,35].

GDNF also plays a role in modulating nociceptive processing, but with contrasting in vitro and in vivo effects. In cultured DRG neurons, GDNF increases CAP sensitivity and TrPV1 expression [36,37], and increases neuropetide content [36]. Inflammation and nerve injury both increase BDNF content in DRG neurons and in the spinal cord, and this increase in BDNF is associated with the maintenance of a hyperalgesic state [38-41]. Furthermore, BDNF is released in the spinal cord upon noxious afferent stimulation [42,43], and peripheral CAP application increases BDNF release at central terminals of sensory neurons [44]. Hence, BDNF might act as a neurotransmitter in the pain pathway in adult animals [45]. The trophic properties of BDNF on adult sensory neurons, particularly nociceptors, are poorly understood.

In brief, our present experimental result indicates that hNSCs produce BDNF and GDNF which can further stimulate its growth as well as DOPamine release in an autocrine / paracrine manner. The understanding of the complete range of properties of this trophic molecule will allow us to investigate its broad mechanisms of action to accelerate and/or improve therapies for the neuro-pathological conditions, like Parkinson’s Disease.
