Abstract

We measure the dispersion of the Cu-O bond-stretching phonon mode in the high-temperature superconducting parent compound $\text{Ca}_{2}\text{CuO}_2\text{Cl}_2$. Our density functional theory calculations predict a cosine-shaped bending of the dispersion along both the $(\xi 00)$ and $(\xi \xi 0)$ directions, while comparison with previous results on $\text{Ca}_{1.84}\text{CuO}_2\text{Cl}_2$ show it only along $(\xi 00)$, suggesting an anisotropic effect which is not reproduced in calculation at optimal doping. Comparison with isostructural $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ suggests that these calculations reproduce well the overdoped regime, however they overestimate the doping effect on the Cu-O bond-stretching mode at optimal doping.

The role of electron-phonon coupling in high-temperature superconducting (HTS) cuprates has been debated since their discovery [1]. Although the general belief is that coupling with phonons is not the main mechanism driving Cooper pair formation in HTS cuprates [2], their role is still not completely understood. For example, the electron-phonon coupling exhibits anomalous doping dependence with a very large oxygen isotope effect close to 1/8 doping [3, 4]. A decade ago, the debate around the role of electron-phonon coupling was revived by the observation of a strong kink in the electronic band dispersion measured by angle-resolved photoemission spectroscopy (ARPES) [5] which was thought to originate from phonon interactions. The Cu-O bond stretching phonon [6–12], which softens with doping, is the most likely candidate for this interaction [13]. Subsequent density functional theory (DFT) calculations [14–16], could explain rather well the phonon softening despite small electron-phonon coupling, but they could not explain the large ARPES kink. However, it was suggested that large couplings may still exist due to many-body effects in the presence of strong electron-electron correlations [17] which are not captured by these DFT calculations.

In this Letter, we present inelastic x-ray scattering (IXS) measurements of the parent compound Ca$_2$CuO$_2$Cl$_2$ [20, 21]. We demonstrate that doping induces a softening of the Cu-O bond-stretching phonon by comparing with previous reports [22] on the vacancy-doped compound Ca$_{1.84}$CuO$_2$Cl$_2$ [23], which is near optimal doping. This result is consistent with the above cited reports of doping-induced softening in other HTS cuprates. The softening however is anisotropic which disagrees with our DFT calculations. We show by comparison with La$_{2-x}$Sr$_x$CuO$_4$ [24], since Ca$_{2-x}$CuO$_2$Cl$_2$ cannot be overdoped, that DFT calculations actually reproduce the strongly overdoped region in HTS cuprates. The failure of the DFT calculations to reproduce this important phonon mode near optimal doping naturally explains its inability to reproduce the observed large ARPES kink. In the future our results on Ca$_2$CuO$_2$Cl$_2$, coupled with previous reports on Ca$_{1.84}$CuO$_2$Cl$_2$ [22], may help bridge this gap between theory and experiment in the HTS cuprates. The Ca$_2$CuO$_2$Cl$_2$ system is ideally suited to advanced many-body calculations trying to capture the predicted larger electron-phonon coupling due to electronic correlations because of its light elements and simple structure [25, 26].

Single crystals of Ca$_2$CuO$_2$Cl$_2$ were grown by the flux method as described in Ref. [19]. The phonons were measured using inelastic x-ray scattering (IXS) at the BL35XU beamline of
FIG. 1. (Color online) The crystallographic unit cell of Ca$_2$CuO$_2$Cl$_2$ with Ca as cyan, Cu as blue, O as red, and Cl as green [18]. The square coordination of Cu with its four nearest-neighbor O ions in the CuO$_2$ planes is shown. The Cl ions are located at the apical sites below/above the Cu ions. The atomic coordinates and displacement ellipsoids are from single-crystal diffraction detailed in Ref. [19].

SPring-8 [27]. Grease/oil was used to protect the hygroscopic samples from air and to mount them on copper sample holders in a cryostat. The cryostat was used just for its vacuum to protect the samples and minimize air scattering. However, the measurements were taken at room temperature which is possible with Ca$_2$CuO$_2$Cl$_2$ because the lower energy modes are weaker due to the low Z atoms and therefore do not wash out the higher energy modes [22]. The main monochromator was set to the Si(999) Bragg reflection giving a wavelength of 0.6968 Å (17.7935 eV) and the beam size at the sample was 0.09 × 0.09 mm$^2$ FWHM (see Ref. [27] for details). The angular width of the (400) Bragg reflection rocking curve from the samples was $\approx 0.3^\circ$ FWHM.

DFT calculations of the phonon dispersion for Ca$_2$CuO$_2$Cl$_2$ and La$_2$CuO$_4$ were car-
ried out using the linear response or density-functional perturbation theory implemented in the framework of the mixed-basis pseudopotential method [28]. The lattice structure of Ca$_2$CuO$_2$Cl$_2$ was fully relaxed prior to the phonon calculations. In the case of La$_2$CuO$_4$, we used the experimental lattice constants of La$_{2-x}$Sr$_x$CuO$_4$ with $x=0.3$ [29] and only relaxed the internal structural parameters. In both systems we have used the stoichiometry of the undoped parent compounds, however the present LDA calculations are unable to describe the charge-transfer insulating ground state and instead predict a metallic state. Thus the calculated phonon dispersions are more representative of the doped compounds. Shell calculations were based on a common interatomic potential model for cuprates [30] and adapted to Ca$_{1.84}$CuO$_2$Cl$_2$ in a previous work [22].

In Fig. 2 we show representative IXS spectra for Ca$_2$CuO$_2$Cl$_2$ (top) and Ca$_{1.84}$CuO$_2$Cl$_2$ (bottom, from Ref. [22]) at the midpoints of the three symmetry lines we explored: $\Delta_1$, longitudinal along $(\xi00)$; $\Delta_3$, transverse along $(0\xi0)$; and $\Sigma_1$, longitudinal along $(\xi\xi0)$. The blue lines are a fit of the entire spectra consisting of Lorentzian functions convoluted with the instrumental function, while the cyan lines shown the Cu-O bond stretching phonon contribution.

Our results are summarized in Fig. 3 where we compare the measured and calculated Cu-O bond-stretching phonon dispersion of Ca$_{2-x}$CuO$_2$Cl$_2$ (left) and La$_{2-x}$Sr$_x$CuO$_4$ (right). Our dispersion from IXS on Ca$_2$CuO$_2$Cl$_2$, shell calculations on La$_{2-x}$Sr$_x$CuO$_4$, and DFT calculations on Ca$_2$CuO$_2$Cl$_2$ and La$_2$CuO$_4$ are complemented by infrared absorption measurements on Ca$_2$CuO$_2$Cl$_2$ [31], shell calculations on Ca$_{2-x}$CuO$_2$Cl$_2$ [22], and dispersion from inelastic neutron scattering (INS) on La$_{2-x}$Sr$_x$CuO$_4$ [24].

Our measurements of Ca$_2$CuO$_2$Cl$_2$ confirm that near optimal doping the Cu-O bond-stretching phonon in Ca$_{2-x}$CuO$_2$Cl$_2$ softens along $\Delta_1$, which agrees with previous reports on La$_{2-x}$Sr$_x$CuO$_4$ and other HTS cuprates [6-12]. However, with respect to the undoped compounds, there is an upward dispersion in Ca$_2$CuO$_2$Cl$_2$ unlike the downward dispersion found in La$_2$CuO$_4$. There is also a doping-induced softening along $\Sigma_1$, however the upward dispersion of Ca$_2$CuO$_2$Cl$_2$ persists with doping unlike the downward bending seen in La$_{2-x}$Sr$_x$CuO$_4$ with doping. We find a strangely fast dispersion along $\Sigma_1$ near the zone center in Ca$_2$CuO$_2$Cl$_2$ which does however decrease upon doping. The measurements along $\Delta_3$ with transverse polarization show no doping dependence, which stresses the fact that only the Cu-O bond stretching mode is softened with doping, as for the other cuprates [6, 8, 12].
FIG. 2. (Color online) Representative inelastic x-ray scattering spectra of Ca$_{2-x}$CuO$_2$Cl$_2$. Measurements on Ca$_2$CuO$_2$Cl$_2$ from this work, shown in the top row, are compared to previous reports on Ca$_{1.84}$CuO$_2$Cl$_2$ [22] shown on the bottom row. Each column shows spectra taken at the propagation vector corresponding to the middle of the Brillouin zone along three different in-plane symmetry lines. Blue lines are fit to the entire data, while the cyan line highlights the contribution from the Cu-O bond stretching mode. The vertical dashed gray line is the position at Γ from infrared absorption [31].

Our DFT and shell model empirical calculations are shown in Fig. 3 as red and black lines respectively. We stress that the DFT calculations are more representative of doped HTS cuprates, despite being performed with an undoped stoichiometry, since they cannot open the charge-transfer gap and instead predict a metallic state. Indeed, we find good agreement between these calculations along Δ$_1$ for both Ca$_{1.84}$CuO$_2$Cl$_2$ and La$_{1.85}$Sr$_{0.15}$CuO$_4$. On the other hand, the shell model empirical calculations account for screening and are fit to doped
FIG. 3. (Color online) Dispersion of Cu-O bonding-stretching phonon in Ca$_{2-x}$CuO$_2$Cl$_2$ (left) and La$_{2-x}$Sr$_x$CuO$_4$ (right). The inelastic x-ray scattering (IXS) on Ca$_2$CuO$_2$Cl$_2$ from this work are plotted along with: infrared absorption (IR) taken at Γ on Ca$_2$CuO$_2$Cl$_2$ [31], IXS on Ca$_{1.84}$CuO$_2$Cl$_2$ [22], and inelastic neutron scattering (INS) on La$_{2-x}$Sr$_x$CuO$_4$ (x={0, 0.1, 0.15, 0.3}) [24]. Shell calculations are shown as black lines and density functional theory (DFT) calculations are shown as red lines.

samples, however they are more representative of undoped HTS cuprates as seen in Fig. 3. Except for a slight shift, the higher optic mode along Δ$_3$ agrees well with shell calculations.

The DFT calculations predict a softening along Σ$_1$ similar to that along Δ$_1$. We found however that near optimal doping DFT calculations fail in both compounds along Σ$_1$. The difference near the zone center is small, however it grows larger near the zone boundary since DFT predicts a strong downward dispersion towards the zone boundary. We find the opposite trend in Ca$_{1.84}$CuO$_2$Cl$_2$ which actually has an upward dispersion, while La$_{1.85}$Sr$_{0.15}$CuO$_4$ does disperse downwards but quite weakly.

The apparent contradiction between theory and experiment is resolved by considering the overdoped HTS cuprates. As shown in the right panel of Fig. 3, the dispersion of La$_{1.7}$Sr$_{0.3}$CuO$_4$ along both Δ$_1$ and Σ$_1$ agrees much better with DFT calculations. We conclude that standard DFT calculations on HTS cuprates overestimate the doping effects of the Cu-O bond-stretching mode.

Unfortunately, a similar comparison cannot be made with Ca$_2$CuO$_2$Cl$_2$ since it has never
been overdoped, neither with sodium \cite{20, 21} nor with vacancies \cite{23}. Nonetheless, our IXS results on Ca$_2$CuO$_2$Cl$_2$ coupled with those on Ca$_{1.84}$CuO$_2$Cl$_2$ \cite{22} provide an experimental test bed for future theoretical calculations trying to improve upon DFT by including correlation effects. In order to minimize relativistic effects, these quantum many-body calculations are mainly done on systems with light atoms \cite{25, 32}. Ca$_{2-x}$CuO$_2$Cl$_2$ and Ca$_{2-x}$Na$_x$CuO$_2$Cl$_2$ are the closest examples to such systems among the bulk HTS cuprates. The Ca$_2$CuO$_2$Cl$_2$ system also has the advantage of a simple single-layer quadratic structure without any doping- or temperature-induced structural transitions which can affect phonon mode frequencies.

The failure of DFT calculations to reproduce the dispersion along Σ$_1$ at optimal doping was also found in YBa$_2$Cu$_3$O$_{6+δ}$ \cite{33} which suggests that this phenomenon is universal in the HTS cuprates. In Ref. \cite{15} the Σ$_1$ mode is not shown, but earlier DFT phonon calculations \cite{34} found a similar difference with experiment. The authors of Ref. \cite{34} noted that the difference was not as drastic and temperature-sensitive as previous models which included Jahn-Teller effects, however they did not elaborate further on the actual difference \cite{35}. Moreover, their calculated frequencies were shifted since they used an idealized tetragonal structure for undoped La$_2$CuO$_4$. On the contrary, our present calculations shown in Fig. 3 use the experimental lattice constants for La$_{1.7}$Sr$_{0.3}$CuO$_4$ and agree with experimental results at Γ and along the other branches without an energy shift. The difference between DFT calculations and experiment along Σ$_1$ in the underdoped to optimally doped regime can be simulated using phenomenological models of the dipole and charge fluctuations \cite{36}, however this technique is not first-principles since it uses a shell-model approach with fitted parameters.

In conclusion, we show that the softening of the Cu-O bond-stretching mode induced by doping in Ca$_{2-x}$CuO$_2$Cl$_2$ is anisotropic near optimal doping, with a marked difference along Δ$_1$ and Σ$_1$, \textit{i.e.} full- and half-breathing modes. This is in striking disagreement with DFT calculations which we show actually reproduces the modes in overdoped cuprates, using La$_{2-x}$Sr$_x$CuO$_4$ as an example. This in turn could explain a smaller calculated effect on the ARPES extracted self-energy in DFT. An anisotropic electron-phonon coupling could be relevant to understanding the physics of cuprate superconductivity as pointed out by \cite{4}, and oxychloride cuprates are an optimal playground to test advanced many-body calculations trying to capture the effects of electronic correlations.
ACKNOWLEDGMENTS

The synchrotron radiation experiments were performed at the BL35XU of SPring-8 with the approval of the Japan Synchrotron Radiation Research Institute (JASRI) (Proposal No. 2015B1720). The authors are very grateful to Lise-Marie Chamoreau for her assistance in sample orientation and acknowledge the use of the x-ray diffractometer instrument at the “Plateforme Diffraction”, IPCM, Paris.
