1. Introduction and Preliminaries

The idea of a metric space was generalized by Czerwik [1] and Bakhtin [2]. They presented metric spaces called $b$-metric spaces. Several researchers took the idea of Czerwik and illustrated interesting results. For details, see [3–7]. For recent generalizations to $b$-metric spaces by employing control functions in the triangle inequality to replace the constant of the $b$-metric triangle inequality, we refer to [8–12] and the references therein.

In 1973, the contraction was introduced by Geraghty [13] in which the contraction constant was quite changed by mapping owing to its interesting properties. After that, several papers for rational Geraghty contractive mappings have appeared (for details, see [14–18]). Khan [19] introduced one of the best works in this line, and Fisher [20] modified it. By rational expressions, Khan [19] and Fisher [20] results were lately extended by Piri et al. [21] by introducing a new general contractive condition. Fixed point results via $F$-Khan contractions were studied by Piri et al. [22] on complete metric spaces, and they discuss their application to integral equations. In [23], Ullah et al. established fixed point results and discuss the application to an infinite system of fractional order differential equations.

Nadler [24] elaborated and extended the Banach contraction principle [25] to set-valued mapping by using the Hausdorff metric. After different generalizations of the Nadler contraction principle, Wardowski [26] introduced a contraction called $F$-contraction. In this way, Wardowski generalized the Banach contraction principle (BCP) in a different manner from the known results of literature. Following this direction, Sgroi and Vetro [27] studied set-valued $F$-contractions and discussed their application on certain functional and integral equations.

Cosentino and Vetro [25] extended $F$-contraction in the setting of $b$-metric spaces and proved some fixed point results. Ali et al. [28] studied the fixed point, generalize the result of Cosentino et al. [25] for a new class of $F$-contractions in the set-
ting of $b$-metric spaces, and apply the result to obtain existence results for Volterra-type integral inclusion in $b$-metric spaces. Several authors generalized $F$-contraction by combining it with some existing contractive conditions (see [27, 29–32]).

In the current work, we derive a hybrid (single and multi-valued) common fixed point result for the $F$-Khan-type contraction in the $b$-metric space. Also, we shall provide an example and applications for the validity of the established result. Throughout this paper, $CB(A)$ indicates the family of nonempty subsets of $A$, which is bounded and closed. $\mathbb{R}^+$, $\mathbb{N}$, and $\mathbb{N}$ signify the set of any nonnegative real numbers, the set of nonnegative integers, and the set of positive integers. Now, we recall a few basic results and definitions.

**Definition 1** [1]. Consider a nonempty set $A$ and let $s \geq 1$. Assume $d : A \times A \rightarrow \mathbb{R}^+$ is a function satisfying the conditions:

1. $d(\xi_1, \xi_2) = 0 \iff \xi_1 = \xi_2$ for all $\xi_1, \xi_2 \in A$
2. $d(\xi_1, \xi_2) > 0$, for all $\xi_1 \neq \xi_2, \xi_2 \in A$
3. $d(\xi_1, \xi_2) = d(\xi_2, \xi_1)$, where $\xi_1, \xi_2 \in A$
4. $d(\xi_1, \xi_2) \leq s(d(\xi_1, \xi_3) + d(\xi_3, \xi_2))$ for all $\xi_1, \xi_2, \xi_3 \in A$

Then, the triple $(A, d, s)$ is called the $b$-metric space.

**Definition 2** [1]. Assume $(A, d, s)$ is a $b$-metric space, where $s \geq 1$. Let $\sigma_n$ be a sequence in $A$. Then, $\sigma \in A$ is said to be the limit of the sequence $\sigma_n$ if

$$\lim_{n \to \infty} d(\sigma_n, \sigma) = 0,$$

and the sequence $\sigma_n$ is said to be convergent in $A$.

**Definition 3** [1]. If for each $e > 0$, there is a positive integer $N$ such that $d(\sigma_n, \sigma_m) < e$ for all $n, m > N$, then a sequence $\sigma_n$ is said to be a $b$-Cauchy sequence.

**Definition 4** [1]. A $b$-metric space $(A, d, s)$ is said to be complete (or a $b$-complete metric space) if every Cauchy sequence in $(A, d, s)$ is convergent in $A$.

**Definition 5** [33]. Assume $s \geq 1$ is a real number and $F$ represents the family of functions $F : \mathbb{R}^+ \rightarrow \mathbb{R}$, with the below conditions:

1. $\forall y \in \mathbb{R}^+$, there is a positive term sequence $\{y_n\}$ such that $F(sy_n) = \omega$ for all $n \in \mathbb{N}$.
2. $\lim_{n \to \infty} y_n = 0 \Rightarrow \lim_{n \to \infty} F(y_n) = \omega$.
3. For each positive number sequence, i.e., $\{y_n\} \subseteq \mathbb{R}^+$ such that $\lim_{n \to \infty} y_n = 0$, there exists $k \in (0, 1)$ such that $\lim_{n \to \infty} (y_n)^{1-k} F(y_n) = 0$.
4. For $\{y_n\} \subseteq \mathbb{R}^+$, such that $\lambda + F(sy_n) \leq F(sy_{n-1}) \forall n \in \mathbb{N}$ and some $\lambda \in \mathbb{R}^+$, then $\lambda + F(sy_n) \leq F(sy_{n-1})$.

Now, we give some basics defined in a $b$-metric space $(A, d, s)$ for set-valued mappings. Define the mapping $H : CB(A) \times CB(A) \rightarrow \mathbb{R}^+$ for $A_1, A_2 \in CB(A)$ by

$$H(A_1, A_2) = \max \{\delta(A_1, A_2), \delta(A_2, A_1)\},$$

where

$$\delta(A_1, A_2) = \sup \{d(a, A_2), a \in A_1\},$$

$$\delta(A_2, A_1) = \sup \{d(b, A_1), b \in A_2\},$$

$$d(a, A) = \inf \{d(a, \sigma), \sigma \in A\}.$$
Theorem 12. Assume \((A, d, s)\) is a complete \(b\)-metric space. Let \((\theta, \Theta)\) be the F-Khan contraction. Further, \(\theta\) is continuous. Then, \(C(\theta, \Theta) \neq \emptyset\).

(i) \(\theta\) and \(\Theta\) have a common fixed point if \(\theta\theta a = a\), and \(\theta\) is occasionally \(\Theta\)-weakly commuting at \(a\). Then, \(\theta\) and \(\Theta\) have a common fixed point

\[
\tau + F(sH(\theta \xi, \Theta \zeta)) \leq F\left(\frac{d(\xi, \theta \xi) + d(\zeta, \theta \zeta)}{\xi + d(\theta \xi, \zeta)}\right),
\]

if \(\max \{d(\xi, \theta \zeta), d(\theta \xi, \zeta)\} \neq 0\),

\[
\tau + F(sH(\Theta \zeta_{2n+1}, \theta \zeta_{2n+1})) \leq F\left(\frac{d(\zeta_{2n}, \theta \zeta_{2n}) + d(\zeta_{2n+1}, \theta \zeta_{2n+1})}{\max \{d(\theta \zeta_{2n}, \zeta_{2n+1}), d(\theta \zeta_{2n+1}, \zeta_{2n+2})\}}\right)
\]

which implies

\[
\tau + F(sH(\theta \zeta_{2n}, \Theta \zeta_{2n+1})) \leq F(d(\zeta_{2n}, \theta \zeta_{2n})).
\]  

We deduce that

\[
\tau + F(sd(\zeta_{2n+1}, \zeta_{2n+2})) \leq F(d(\zeta_{2n}, \zeta_{2n+1})).
\]  

Let \(Q_n = d(\zeta_{2n+1}, \zeta_{2n+2}) > 0, \forall n \in \mathbb{N}\). It follows from (12) and axiom \(F_4\) that

\[
\tau + F(s^d(\zeta_{2n+1}, \zeta_{2n+2})) \leq F(s^{d-1} d(\zeta_{2n}, \zeta_{2n+1})), \quad \forall n \in \mathbb{N}.
\]  

Thus, by equation (13),

\[
F(s^n Q_n) \leq F(s^{n-1} Q_{n-1}) - \tau,
\]

\[
F(s^{n-1} Q_{n-1}) \leq F(s^{n-2} Q_{n-2}) - 2\tau,
\]

\[
F(s^n Q_{n-1}) \leq F(s^n Q_0) - n\tau,
\]

which implies that

\[
\lim_{n \to \infty} F(s^n Q_n) = -\infty.
\]  

By using \(F_2\), we have

\[
\lim_{n \to \infty} s^n Q_n = 0.
\]  

By the \(F_3\) property, there exists \(0 < k < 1\) such that

\[
\lim_{n \to \infty} (s^n Q_n)^k F(s^n Q_n) = 0.
\]  

Equation (14) implies that

\[
F(s^n p_n) \leq F(p_0) - n\tau.
\]  

Multiplying (18) by \((s^n p_n)^k\), we have

\[
(s^n p_n)^k F(s^n p_n) \leq (s^n p_n)^k F(p_0) - n\tau (s^n p_n)^k,
\]  

which implies that

\[
(s^n p_n)^k F(s^n p_n) - (s^n p_n)^k F(p_0) \leq -n\tau (s^n p_n)^k \leq 0.
\]  

Applying limit \(n \to 1\), we have

\[
\lim_{n \to \infty} (s^n p_n)^k = 0.
\]  

From (21), there exists \(n_1 \in \mathbb{N}\) such that \(n(s^n Q_n)^k < 1\) such that

\[
(s^n Q_n)^k \leq \frac{1}{nn_1^k}, \quad \forall n \geq n_1.
\]  

To show that \(\{\zeta_n\}\) is a \(b\)-Cauchy sequence, consider \(m, n \in \mathbb{N}\) such that \(m > n > n_1\), using triangular inequality, and using (18), we have
\[ d(\zeta_{2n}, \zeta_{2m}) \leq s d(\zeta_{2n}, \zeta_{2n+1}) + s^2 d(\zeta_{2n+1}, \zeta_{2n+2}) + \cdots + s^{m-n} d(\zeta_{2m-1}, \zeta_{2m}) = s^m Q_n + s^2 Q_{n+1} + \cdots + s^{m-n} Q_{m-1} \]
\[ \leq \sum_{j=n}^{\infty} s^{j-n+1} Q_j \]
\[ \leq \sum_{j=n}^{\infty} s^{j-n+1} \frac{1}{j^k}. \]  

By taking limit, we get \( d(\zeta_n, \zeta_m) \longrightarrow 0 \). Hence, \( \{\zeta_n\} \) is a \( b \)-Cauchy sequence, but a \( b \)-metric space \((\Lambda, d, s)\) is a complete space there exists \( \zeta \in \Lambda \) such that \( \zeta_n \longrightarrow \zeta \) as \( n \longrightarrow \infty \).

The next step is to show that \( \zeta \) is a common fixed point of the mapping \( \Theta \) and \( \theta \). We have
\[ d(\zeta_{2n+2}, \Theta \zeta) \leq s H(\Theta \zeta, 2n+1, \Theta \zeta) \leq s H(\Theta \zeta, 2n+1, \Theta \zeta), \]
which implies that
\[ d(\zeta_{2n+2}, \Theta \zeta) \leq s H(\Theta \zeta, 2n+1, \Theta \zeta). \]

Since \( F \) is strictly increasing, therefore
\[ F(d(\zeta_{2n+2}, \Theta \zeta)) \leq F(s H(\Theta \zeta, 2n+1, \Theta \zeta)). \]
Adding \( \tau \) to both sides and using equation (7), we have
\[ \tau + F(d(\zeta_{2n+2}, \Theta \zeta)) \leq \tau + F(s H(\Theta \zeta, 2n+1, \Theta \zeta)) \]
\[ \leq F\left( \frac{d(\zeta_{2n+1}, \Theta \zeta_2 n) d(\zeta_{2n}, \Theta \zeta) + d(\zeta, \Theta \zeta d(\zeta, \Theta \zeta))}{\max \{ d(\zeta_{2n+1}, \Theta \zeta_2 n), \Theta \zeta \}} \right). \]

Since \( \tau \in \mathbb{R}^+ \), we have
\[ F(d(\zeta_{2n+2}, \Theta \zeta)) \]
\[ \leq F\left( \frac{d(\zeta_{2n+1}, \Theta \zeta_2 n) d(\zeta_{2n}, \Theta \zeta) + d(\zeta, \Theta \zeta d(\zeta, \Theta \zeta))}{\max \{ d(\zeta_{2n+1}, \Theta \zeta_2 n), \Theta \zeta \}} \right). \]

Since \( F \) is strictly increasing, therefore
\[ d(\zeta_{2n+2}, \Theta \zeta) \leq \left\{ \begin{array}{ll} \frac{d(\zeta_{2n+1}, \Theta \zeta_2 n) d(\zeta_{2n}, \Theta \zeta) + d(\zeta, \Theta \zeta d(\zeta, \Theta \zeta))}{\max \{ d(\zeta_{2n+1}, \Theta \zeta_2 n), \Theta \zeta \}} & \text{if } \max \{ d(\zeta_{2n+1}, \Theta \zeta_2 n), \Theta \zeta \} \neq 0, \\
0 & \text{if } \max \{ d(\zeta_{2n+1}, \Theta \zeta_2 n), \Theta \zeta \} = 0. \end{array} \right. \]

**Corollary 13.** Assume \((\Lambda, d, s)\) is a complete \( b \)-metric space. Let \( \Theta \) be an \( F \)-Khan contraction. Then, \( \Theta \) has a fixed point.

Consider the following class of function.

**Definition 14.** Assume \( s \geq 1 \) is a real number and \( \mathbb{F}_1 \) represents the family of functions \( F: \mathbb{R}^+ \longrightarrow \mathbb{R} \), which is strictly increasing.

**Definition 15.** Let \((\Lambda, d, s)\) be a \( b \)-metric space. Let \( \theta: \Lambda \longrightarrow \Lambda \) and \( \Theta: \Lambda \longrightarrow CB(\Lambda) \) be two mapping. Then, \( \Theta \) is said to be the \( F \)-Khan contraction w.r.t \( \theta \) if there exists \( 0 < \tau < \infty \) and \( F \in \mathbb{F}_1 \) such that for all \( \xi, \zeta \in \Lambda \), max \( \{ d(\xi, \Theta \zeta), d(\Theta \xi, \zeta) \} \neq 0 \), then, \( \Theta \xi \neq \Theta \zeta \) and

\[ \tau + F(s H(\Theta \xi, \Theta \zeta)) \leq \left\{ \begin{array}{ll} \frac{d(\xi, \Theta \xi d(\xi, \Theta \zeta) + d(\zeta, \Theta \zeta d(\xi, \Theta \zeta))}{\xi \max \{ d(\xi, \Theta \xi), d(\Theta \xi, \zeta) \}} & \text{if } \max \{ d(\xi, \Theta \xi), d(\Theta \xi, \zeta) \} \neq 0, \\
0 & \text{if } \max \{ d(\xi, \Theta \xi), d(\Theta \xi, \zeta) \} = 0. \end{array} \right. \]

**Theorem 16.** Assume \((\Lambda, d, s)\) is a complete \( b \)-metric space. Let \((\theta, \Theta)\) be an \( F \)-Khan contraction. Further, if \( \theta \) is continuous, then \( C(\theta, \Theta) \neq \emptyset \).

(i) \( \theta \) and \( \Theta \) have a common fixed point if \( \theta \alpha = \alpha \) and \( \alpha \) is occasionally \( \Theta \)-weakly commuting at \( \alpha \). Then, \( \theta \) and \( \Theta \) have a common fixed point

**Remarks.** Our result extended the results of

(i) Fisher [20] for set-valued mapping in the setting of \( b \)-metric spaces
(ii) Khan [19] for set-valued mapping in \( b \)-metric spaces
(iii) Piri et al. [21, 22] for set-valued mapping in \( b \)-metric spaces
Example 17. Consider the sequence \( \{S_q\} : q \in \{1, 2 \cdots 100\} \) as follows:

\[
S_1 = 1.2, S_2 = 2.3, \cdots, S_q = q(q + 1).
\]  

Let \( \Lambda = \{S_q : q \in \{1, 2, \cdots, 100\} \} \) and \( d : \Lambda \times \Lambda \rightarrow [0, \infty) \) be defined by

\[
d(\xi, \zeta) = \max \{\xi, \zeta\}^2, \text{ if } \xi \neq \zeta \text{ and } d(\xi, \zeta) = 0, \text{ if } \xi = \zeta. \tag{35}\n\]

Then, \( (\Lambda, d, s) \) is a complete \( b \)-metric space. Define the mapping \( \Theta : \Lambda \rightarrow CB(\Lambda) \) by

\[
\Theta(S_1) = \{S_1\}, \Theta(S_q) = \{S_{q-1}\}. \tag{36}\n\]

Multiplying 1.01 on both sides and taking log to the base \( e \) on both sides, we get inequality (7) and also find that \( \tau = 0.004365 \cdots \). Therefore, \( \theta \) and \( \Theta \) have a fixed point.

3. Application to Force Damping Oscillation

Throughout in this section, \( \max \{d(h, \theta k), d(\theta h, k)\} \neq 0 \).

Assume that an object of mass \( m \) moves to and fro on the \( x \)-axis around an equilibrium position \( x = 0 \) (see Figure 1). The object has position \( x(t) \) at time \( t \). It undergoes a force due to a spring:

\[
F_s = -kx, \tag{40}\n\]

Furthermore, a damping force that resists the movement of the object is shown:

\[
F_d = b \frac{dx}{dt}. \tag{41}\n\]

Now, by the second law of motion,

\[
F_{\text{net}} = m \frac{d^2x}{dt^2}, \tag{42}\n\]

where \( m, k, \) and \( b \) are all positive constants. Up to that feature, the system is simply the damped harmonic oscillator.

Now, suppose the additional time-dependent force \( f(t) \) is applied to the object. Then, by Newton’s second law,

\[
-kx - b \frac{dx}{dt} + f(t) = m \frac{d^2x}{dt^2} + m \frac{d^2x}{dt^2} + \frac{b}{k} \frac{dx}{dt} + kx \tag{43}\n\]

The problem (43) can be written in the form of the Fredholm integral equation:

\[
\Lambda \rightarrow \Lambda \]
\[ v(t_1) = \int_0^1 G((\beta, s))\Theta_1(t_1, s_1) ds_1, \quad t_1 \in [0, 1]. \quad (44) \]

Here, Green’s function for critically damping oscillation is defined as

\[ \mathcal{G}(\beta, s_1) = \begin{cases} -s_1 e^{\gamma(s-t)}, & 0 \leq s_1 \leq \beta \leq 1, \\ -e^{\gamma(t-s)}, & 0 \leq \beta \leq s_1 \leq 1, \end{cases} \quad (45) \]

where \( \gamma \) can be found in terms of \( m, b, \) and \( k \).

Let \( \Lambda = C[0, 1] \) be the set of all continuous functions defined on \([0, 1]\). For \( u \in C([0, 1]) \), define the supremum norm as

\[ ||v|| = \left( \sup_{t_1 \in [0, 1]} |v(t_1)| \right) e^{-\tau}. \quad (46) \]

Let \( C([0, 1], \mathbb{R}) \) be endowed with the \( b \)-metric:

\[ d(v, \zeta) = \sup_{t_1 \in [0, 1]} ||v(t_1) - \zeta(t_1)|| e^{-\tau}. \quad (47) \]

With these contexts, \( C([0, 1], \mathbb{R}, ||||) \) becomes the Banach space. We give the following theorem.

**Theorem 18.** Assume the assumptions given below hold.

(A1) There exists a continuous function \( \Theta_1 : [0, 1] \times [0, 1] \rightarrow [0, \infty) \) and for \( t_1, s_1 \in [0, 1] \) such that

\[ ||\Theta_1(t_1, s_1, u) - \Theta_1(t_1, s_1, v)|| \leq \sqrt{\frac{e^{-\tau}}{s}} M_s(h, k), \]

\[ M_s(h, k) = \sqrt{\frac{e^{-\tau}}{s}} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta h), d(\theta h, k)\}} \right\}, \quad (48) \]

where \( \Theta : C([0, 1], \mathbb{R}) \rightarrow C([0, 1]) \) is any function.

(A2) \( \int_0^1 G(\beta, s_1) ds_1 \leq 1 \), for some \( \tau > 0 \).

Then, the problem (43) has a solution in \( C([0, 1]) \).

**Proof.** Define \( \Theta : C([0, 1]) \rightarrow C([0, 1]) \) by

\[ \Theta v(t_1) = \int_0^1 G((\beta, s_1))\Theta_1(t_1, s_1) ds_1, \quad t_1 \in [0, 1]. \quad (49) \]

We have

\[ ||\Theta v - \Theta \zeta|| \leq \frac{1}{\sqrt{s}} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta h), d(\theta h, k)\}} \right\}. \quad (50) \]

Squaring both sides, we get

\[ ||\Theta v - \Theta \zeta||^2 \leq \frac{1}{2} e^{-\tau} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta h), d(\theta h, k)\}} \right\}. \quad (51) \]

Multiplying on both sides \( e^{-2\tau} \) and taking sup, we get

\[ sd(\Theta v, \Theta \zeta) \leq e^{-2\tau} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta h), d(\theta h, k)\}} \right\}. \quad (52) \]

By taking \( F(v) = \ln(v) \) from Theorem 12, the integral equation (44) has a common solution.

Similarly, we can apply our theorem for the existence of underdamping oscillation and overdamping oscillation.

**4. Application to Infinite Systems of Fractional Order Differential Equations**

Now, we have to derive sufficient conditions for the solutions in space \( c \) to the following nonlinear infinite systems of fractional order differential equations:

\[ \begin{aligned}
\theta_a &= e^{-\tau} \frac{b(t)}{b(t)} b_i(t) \theta_j + \theta_j(\theta, \eta_1, \eta_2, \cdots), & a_i \in (0, 1), \\
\theta^\beta_j &= e^{-\tau} \frac{b(t)}{b(t)} b_j(t) \theta_j + \theta_j(\theta, \eta_1, \eta_2, \cdots), & \beta_j \in (0, 1),
\end{aligned} \quad (53) \]

with the initial condition \( \theta_0 = \theta_0^\beta \), where \( t \in \mathcal{J}, i, j = 1, 2, \cdots \), and \( \tau \) is the positive real number. \( \mathcal{J} \) is any fixed interval on the real line. Let \( \Lambda = c \) be the space of all real sequences whose limit is finite.

\[ ||\eta|| = (\sup ||\eta||) e^{-\tau}. \quad (54) \]
Let \((c, \mathbb{R})\) be endowed with the \(b\)-metric:
\[
d(\eta, \vartheta) = \sup \|\eta - \vartheta\| e^{-t}.
\]

**Theorem 19.** Assume the assumptions given below hold.

\(\begin{align*}
(A_1) & \quad \vartheta^b \in c, \vartheta = (\vartheta_1, \vartheta_2, \cdots) : J \times c \longrightarrow c, \\
(A_2) & \quad b_1(t) \text{ represents the continuous function on } J, \\
(A_3) & \quad |\vartheta(t, \eta) - \vartheta(t, \vartheta)| \\
& \leq \frac{e^{-t}}{2s} \left\{ \frac{(d(\eta, \vartheta, \vartheta) + d(\vartheta, \vartheta, \vartheta))}{\eta \{d(\eta, \vartheta, \vartheta), d(\vartheta, \vartheta, \vartheta)\}} \right\}^{1/2}, \\
(A_4) & \quad |b_1(t)\eta - b_1(t)\vartheta| \\
& \leq \frac{b(t)}{2s} \left\{ \frac{(d(\eta, \vartheta, \vartheta) + d(\vartheta, \vartheta, \vartheta))}{\eta \{d(\eta, \vartheta, \vartheta), d(\vartheta, \vartheta, \vartheta)\}} \right\}^{1/2},
\end{align*}\]

where \(\eta = (\eta_1, \eta_2, \eta_3 \cdots)\) and \(\vartheta = (\vartheta_1, \vartheta_2, \vartheta_3 \cdots)\).

then, the infinite systems of fractional order differential equation (53) have a common solution in \(c\).

**Proof.** Define \(h_i(t, \eta), h_i(t, \vartheta): J \times c \longrightarrow c\) by
\[
\begin{align*}
& h_i(t, \eta) = \frac{e^{-t}}{b(t)} b_i(t)\eta_i + \vartheta_i(\eta_1, \eta_2, \cdots), \\
& h_i(t, \vartheta) = \frac{e^{-t}}{b(t)} b_i(t)\vartheta_i + \vartheta_i(\vartheta_1, \vartheta_2, \cdots).
\end{align*}
\]

We have
\[
|h_i(t, \eta) - h_i(t, \vartheta)|
\]
\[
= \left| \frac{e^{-t}}{b(t)} b_i(t)\eta_i + \vartheta_i(\eta_1, \eta_2, \cdots) \right| \\
- \left| \frac{e^{-t}}{b(t)} b_i(t)\vartheta_i + \vartheta_i(\vartheta_1, \vartheta_2, \cdots) \right|
\]
\[
\leq \left| \frac{e^{-t}}{b(t)} b_i(t)\eta_i - \frac{e^{-t}}{b(t)} b_i(t)\vartheta_i \right|
\]
\[
+ \left| \vartheta_i(\eta_1, \eta_2, \cdots) - \vartheta_i(\vartheta_1, \vartheta_2, \cdots) \right|
\]
\[
\leq \frac{e^{-t}}{2s} \left\{ \frac{(d(\eta, \vartheta, \vartheta) + d(\vartheta, \vartheta, \vartheta))}{\eta \{d(\eta, \vartheta, \vartheta), d(\vartheta, \vartheta, \vartheta)\}} \right\}^{1/2}
\]
\[
+ \frac{e^{-t}}{2s} \left\{ \frac{(d(\eta, \vartheta, \vartheta) + d(\vartheta, \vartheta, \vartheta))}{\eta \{d(\eta, \vartheta, \vartheta), d(\vartheta, \vartheta, \vartheta)\}} \right\}^{1/2}.
\]

Squaring both sides, we get
\[
|h_i(t, \eta) - h_i(t, \vartheta)|^2 e^{-t}
\]
\[
\leq \frac{e^{-2t}}{s^2} \left\{ \frac{(d(\eta, \vartheta, \vartheta) + d(\vartheta, \vartheta, \vartheta))}{\max \{d(\eta, \vartheta, \vartheta), d(\vartheta, \vartheta, \vartheta)\}} \right\}.
\]

Taking the supremum, we get
\[
s^2 d(h_i(t, \eta) - h_i(t, \vartheta))
\]
\[
\leq e^{-t} \left\{ \frac{(d(\eta, \vartheta, \vartheta) + d(\vartheta, \vartheta, \vartheta))}{\max \{d(\eta, \vartheta, \vartheta), d(\vartheta, \vartheta, \vartheta)\}} \right\}.
\]

By taking \(F(\nu) = \ln(\nu)\) from Theorem 12, the infinite systems of fractional order differential equation (53) have a common solution.

**5. Application to Functional Equations**

In this section, we study the solvability of functional equations using the established fixed point theorem.

Let \(A_1\) and \(A_2\) be Banach spaces, \(\Theta_1 \subset A_1, \Theta_2 \subset A_2\), and \(R\) be the field of real numbers. Suppose \(\Lambda = B(\Theta_1)\) represents the set of all functions defined on \(\Theta_1\) which is bounded and real valued. Define \(d: \Lambda \times \Lambda \longrightarrow \mathbb{R}^+\) by
\[
d(\nu, \zeta) = |\nu - \zeta|^2.
\]

Then, \((\Lambda, d, s)\) is called the \(b\)-metric space. Consider the system of functional equations given as
\[
\begin{align*}
\nu(\zeta) &= \sup_{\zeta \in \Theta_2} \left\{ g(\nu(\zeta), \varphi_1(\nu(\zeta), \zeta, Q(\tau(\nu(\zeta)))) \right\}, \quad \nu \in \Theta_1, \\
\zeta(\varphi_2) &= \sup_{\varphi_2 \in \Theta_2} \left\{ g(\varphi_2(\nu(\zeta), \zeta, Q(\tau(\nu(\zeta)))) \right\}, \quad \varphi_2 \in \Theta_1.
\end{align*}
\]

Here, \(g: \Theta_1 \times \Theta_2 \longrightarrow \mathbb{R}\) and \(\Phi_1, \varphi_2: \Theta_1 \times \Theta_2 \times \mathbb{R} \longrightarrow \mathbb{R}\) are functions which are bounded. \(\Theta_1\) and \(\Theta_2\) are the state and decision spaces, respectively. \(\tau: \Theta_1 \times \Theta_2 \longrightarrow \Theta_1\) shows the transformation of the process, and \(p(\nu)\) and \(q(\nu)\) signify sup return functions with initial state \(\Lambda\). Let \(\Theta, \varphi: B(\Theta_1) \longrightarrow B(\Theta_1)\) be defined by
\[
\Theta(h_1(\nu)) = \sup_{\zeta \in \Theta_2} \left\{ g(h_1(\nu), \varphi_1(\nu, \zeta, P(\tau(\nu(\zeta)))) \right\}, \quad \nu \in \Theta_1, \\
\varphi(h_1(\nu)) = \sup_{\varphi_2 \in \Theta_2} \left\{ g(h_1(\nu), \varphi_2(\nu, \zeta, P(\tau(\nu(\zeta)))) \right\}, \quad \nu \in \Theta_1.
\]

**Theorem 20.** Let \(\Phi_1, \varphi_2: \Theta_1 \times \Theta_2 \times \mathbb{R} \longrightarrow \mathbb{R}\) and \(g: \Theta_1 \times \Theta_2 \longrightarrow \mathbb{R}\) be continuous and bounded and satisfy the following assumption.
Proof. Let \( \delta \) be an arbitrary positive number, \( v \in \Theta_1 \), and \( h_1, h_2 \in B(\Lambda) \); then, there exist \( \zeta_1, \zeta_2 \in \Theta_2 \) such that

\[
\Theta(h_1(v)) < \Phi_1(v, \zeta_1, h_1(\tau_{v, \zeta_1})) + \delta, \\
\Theta(h_2(v)) < \Phi_1(v, \zeta_2, h_2(\tau_{v, \zeta_2})) + \delta, \\
\Theta(h_1(v)) \geq \Phi_1(v, \zeta_2, h_2(\tau_{v, \zeta_2})), \\
\Theta(h_2(v)) \geq \Phi_1(v, \zeta_1, h_1(\tau_{v, \zeta_1})).
\]

Using equations (66) and (69),

\[
\Theta(h_1(v)) - \Theta(h_2(v)) \\
\leq \Phi_1(v, \zeta_1, h_1(\tau_{v, \zeta_1})) - \Phi_1(v, \zeta_1, h_1(\tau_{v, \zeta_1}))) + \delta \\
\leq \Phi_1(v, \zeta_1, h_1(\tau_{v, \zeta_1})) - \Phi_1(v, \zeta_2, h_2(\tau_{v, \zeta_2}))) + \delta \\
\leq \Phi_1(v, \zeta_2, h_2(\tau_{v, \zeta_2})) - \Phi_1(v, \zeta_2, h_2(\tau_{v, \zeta_2}))) + \delta \\
\leq \Phi_1(v, \zeta_1, h_1(\tau_{v, \zeta_1})) - \Phi_1(v, \zeta_1, h_1(\tau_{v, \zeta_1}))) + \delta \\
\leq e^{-r} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta k), d(\theta, k)\}} \right\} + \delta.
\]

It follows that

\[
\Theta(h_1(v)) - \Theta(h_2(v)) \\
\leq e^{-r} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta k), d(\theta, k)\}} \right\} + \delta.
\]

Similarly, using equations (67) and (68), we have

\[
\Theta(h_2(v)) - \Theta(h_1(v)) \\
\leq e^{-r} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta k), d(\theta, k)\}} \right\} + \delta.
\]

Using equations (71) and (72), we get

\[
|\Theta(h_1(v)) - \Theta(h_2(v))| \\
\leq e^{-r} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta k), d(\theta, k)\}} \right\} + \delta,
\]

for all \( v \in \Theta_1 \), and \( \delta > 0 \) is arbitrary; therefore,

\[
s(|\Theta(h_1(v)) - \Theta(h_2(v))|^2) \\
\leq e^{-2r} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta k), d(\theta, k)\}} \right\}^2.
\]

Taking logarithms, we have

\[
\ln \left( s(|\Theta(h_1(v)) - \Theta(h_2(v))|^2) \right) \\
\leq \ln \left( e^{-2r} \left\{ \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta k), d(\theta, k)\}} \right\}^2 \right).
\]

After simple calculation, we get

\[
2r + \ln \left( s(|\Theta(h_1(v)), \Theta(h_2(v))|) \right) \\
\leq \ln \left( \frac{d(h, \theta h) d(h, \theta k) + d(k, \theta k) d(k, \theta h)}{\max \{d(h, \theta k), d(\theta, k)\}} \right).
\]

By taking \( F(v) = \ln (v) \) from Theorem 12, the system of functional equation (63) has a common solution.
