αS Evolution from 35 GeV to 202 GeV
and Flavour Independence

O. Biebel

Max-Planck-Institut für Physik
80805 Munich, Germany
Determinations of the strong coupling constant $\alpha_S$ at centre-of-mass energies of 192 through 202 GeV at LEP are presented. The energy evolution of $\alpha_S$ is in agreement with the prediction of QCD. The combined investigation of OPAL and JADE data in the energy range of 35 through 189 GeV yields $\alpha_S(m_Z) = 0.1187^{+0.0034}_{-0.0019}$. The strength of the strong coupling is flavour independent if quark mass effects are taken into account.

1 Motivation

Three fundamental properties follow from QCD: (i) the scale dependence of the renormalised coupling strength, (ii) the flavour independence of the coupling apart from effects due to finite quark masses, and (iii) the scale dependence of the renormalised quark masses. It constitutes a significant experimental test of QCD if the strong interaction obeys these properties.

The large range of energy covered by $e^+e^-$ colliders makes an investigation of the energy evolution of $\alpha_S$ possible. Although the expected running of the coupling is more pronounced towards lower centre-of-mass energies, the uniform analyses at LEP provide significant QCD tests up to the highest energies accessible.

2 $\alpha_S(200$ GeV)

The excellent performance of the LEP collider in 1999 provided data at $\sqrt{s} = 192$, 196, 200, and 202 GeV comprising together about 220 pb$^{-1}$ per experiment. The results at each of the four $\sqrt{s}$ will be combined to derive the coupling strength at $\sqrt{s} = 198$ GeV which is the luminosity weighted average energy.
Even though the selection of hadronic final states is trivial, background contributions from essentially W pair production and large initial state radiation have to be rejected. W pair events are excluded using the wide separation of the four jets and requiring di-jet masses different from the W mass. The demand that the effective centre-of-mass energy of the hadronic final state is within 10-20% of the nominal value is applied against initial state radiation events. These criteria select more than 75% of the real hadronic final states and reduce the contribution from other processes to less than 20%.

From the selected events the observables thrust ($T$), heavy jet mass ($M_H$), total and wide jet broadening ($B_T$, $B_W$), $C$ parameter ($C$), and the value of the jet resolution parameter at the transition from 3 to 2 jets using the Durham jet algorithm ($y_3$) are measured. The strong coupling constant is found from fitting the QCD prediction, convolved with the hadronisation correction, to the distribution of an observable. The QCD prediction is the matched resummed next-to-leading logarithmic approximation (NLLA) with the full second order matrix element ($O(\alpha_S^2)$). The hadronisation correction is taken from various Monte Carlo event generators which although they were tuned to describe the data measured at 91 GeV yield a good representation of the data at energies of around 200 GeV.

The left part of Fig. 1 shows the fit results of the LEP experiments for $\alpha_S$ at $\sqrt{s} = 192-196$ and 200-202 GeV. Combining the values yields $\alpha_S(198 \text{ GeV}) = 0.109 \pm 0.001_{\text{expt}} \pm 0.005_{\text{theo}}$.

### 3 Energy evolution

The LEP experiments contributed a large number of $\alpha_S$ determinations for $\sqrt{s} \geq m_Z$ (see and references therein). Exploiting initial and hard final state photon radiation, $\sqrt{s}$ as low as 30 GeV are accessible and have been investigated by L3 and DELPHI. These determinations of $\alpha_S$ below the Z mass are complemented by results of experiments at lower centre-of-mass energies which, even though already completed since long, re-analysed their data to employ the matched resummed NLLA and $O(\alpha_S^2)$ predictions for an $\alpha_S$ determination.

The right part of Fig. 1 shows the $\alpha_S$ values versus the centre-of-mass energy. The values with their experimental errors are fitted with the 4-loop formula for the scale dependence of $\alpha_S$. To estimate the theory uncertainty the scale uncertainties of the single measurements are considered to be fully correlated. The fit yields $\alpha_S(m_Z) = 0.1208 \pm 0.0006_{\text{expt}} \pm 0.0048_{\text{theo}}$ which is not dominated by the single measurement at 91.2 GeV and which agrees with the world average of $0.1184 \pm 0.0031$. 

![Figure 1: Left: $\alpha_S$ results at the highest LEP energies. The experimental contribution to the total errors is indicated. Right: $\alpha_S$ between $\sqrt{s} = 22$ and 202 GeV, fitted with the 4-loop prediction of the scale dependence.](image-url)
Recently jet observables for the Durham and Cambridge jet algorithms have been investigated using data of the OPAL and the JADE experiments. The analysis treated the data of both experiments and estimated the errors of $\alpha_S$ in a similar way. Fig. 2 shows the 2-, 3-, 4-, and 5-jet fractions for the Durham jet algorithm at three different $\sqrt{s}$. Predictions of several models are overlaid. The coupling strength has been obtained from fits of the matched resummed NLLA plus second order matrix element to the differential 2-jet rate ($D_2$) and the jet multiplicity ($N$) of both jet finders. Fig. 3 shows the results with the world average overlaid. Combining all eight determinations and taking correlations into account yields $\alpha_S (m_Z) = 0.1187 \pm 0.0010 \text{ (expt)} +0.0032 -0.0016 \text{ (theo)}$ which is in excellent agreement with the world average and has a very small total error.

4 Flavour independence

Finite quark masses affect the result of $\alpha_S$ determinations. In particular bottom quark events at the Z mass yield a 7% lower value of $\alpha_S$ if the quark mass effect is neglected. To account for the mass effect for an inclusive determination which neglected this effect, the value of $\alpha_S$ has to be increased by about 1%, which is covered by the typical total error.

Being precisely confirmed for the heavy charm and bottom quarks, the flavour independence has been scarcely tested for the light quarks at high energies. At $\sqrt{s} \approx 0$ evidence for the flavour independence comes from e.g. isospin invariance and approximate $SU(3)_{flav}$ symmetry. The challenge for an investigation of the flavour independence at $\sqrt{s} = m_Z$ is to separate $u$, $d$, and $s$ quark events. Using the leading particle effect for $K^\pm$, $K^0_S$, and all kinds of charged particles OPAL selected events which are enriched differently in $u$, $d$, and $s$ quarks and thus allows for a statistical decomposition of the contribution of each of the three light quark flavours. $\alpha_S$ is determined from the charged multiplicities, $\langle N \rangle$, obtained for each quark flavour from the decomposition, using $\langle N \rangle \sim \alpha_B \cdot \exp(C/\sqrt{\alpha_S})$ where $B$ and $C$ are known from QCD calculations. This yielded the preliminary ratios: $\frac{\alpha_u^S}{\alpha_d^S} = 0.88 \pm 0.08$, $\frac{\alpha_s^S}{\alpha_d^S} = 0.96 \pm 0.06$, and $\frac{\alpha_s^S}{\alpha_u^S} = 1.09 \pm 0.06$ which are consistent with flavour independence at a level of better than 10% and constitute an improvement over the previous OPAL result.
5 Summary

QCD is in a very good shape! The fundamental properties of the theory, i.e. the running of $\alpha_S$, its flavour independence and also the running of the renormalised quark masses are observed and confirmed in experimental investigations. At the highest energies of LEP the value of the coupling is determined to be $\alpha_S(198 \text{ GeV}) = 0.109 \pm 0.005 \text{ (prelim.)}$ which agrees with the expected running. The value of the strong coupling constant is now very precisely determined from a combined analysis of OPAL and JADE data covering centre-of-mass energies from $\sqrt{s} = 22$ through 189 GeV to be $\alpha_S(m_Z) = 0.1187^{+0.0034}_{-0.0019}$. The flavour independence of the coupling at high energies is now confirmed for the light quarks at the level of better than 10%.
