Abstract

In this paper, we study the geometry of rectifying curves in the 3-dimensional hyperbolic space $\mathbb{H}^3(-r)$. Further we obtain the distance function in terms of arc length when the rectifying curve lying in the upper half plane. Then we find the distance function and also give the general equations of the curvature and torsion of rectifying general helices in $\mathbb{H}^3(-r)$.

Keywords. rectifying curve, general helix, geodesic, hyperbolic space $\mathbb{H}^3(-r)$

1. Introduction

In [4], B.Y. Chen gave the idea that the ratio of torsion and curvature of a regular curve is a linear function of arc length, i.e., $(\tau/\kappa)(s) = c_1 s + c_2$ for some constants $c_1$ and $c_2$. If $c_1 = 0$, we obtain generalized helices; otherwise, we obtain rectifying curves. A space curve whose position vector always lies in its rectifying plane is called rectifying curve. So, a curve $\gamma$ is said to be rectifying curve if there exist a point $r$ in $\mathbb{R}^3$ such that $\gamma(s) - r = C_1 B(s) + C_2 T(s)$, where $C_1, C_2$ are some function of arc length $s$. Now the Frenet frame: $T = \gamma'$, $N, B = T \times N$ of a unit speed curve $\gamma$ in $\mathbb{R}^3$ satisfies the Serret-Frenet equations:

$$
\begin{pmatrix}
T' \\
N' \\
B'
\end{pmatrix} =
\begin{pmatrix}
0 & \kappa & 0 \\
-\kappa & 0 & \tau \\
0 & -\tau & 0
\end{pmatrix}
\begin{pmatrix}
T \\
N \\
B
\end{pmatrix},
$$

where the function $\kappa(s) > 0$ and $\tau(s)$ are called the curvature and the torsion of the curve and the above matrix is skew-symmetric. Therefore at each point of the curve we always get three planes namely: $\{T,N\}$-osculating plane, $\{N,B\}$-normal plane, $\{B,T\}$-rectifying plane and the equations of the corresponding planes are $(R-r).B = 0, (R-r).T = 0, (R-r).N = 0$, where $R$-position vector of any point on the respective plane, $r$-position vector of a specified point of the given curve. To know more about the characterization of rectifying curve we refer the reader to see [1], [2], [6]. In [8], P. Lucas and J.A.O. Yagues, studied rectifying curves in the three-dimensional hyperbolic space, and obtain some results of characterization and classification for such kind of curves.

In [5], S. Izumiya and N. Takeuchi introduced the notion of slant helix, if the principle normal lines of $\gamma$ makes a constant angle with a fixed direction, also they found a necessary and sufficient condition for a curve $\gamma$ with $\kappa(s) > 0$ to be a slant helix is that function $\sigma = \frac{\kappa^2}{(\kappa^2 + \tau^2)^{3/2}}(\frac{s}{r})^3$ be constant. Further in [7], P. Lucas and J.A.O Yagues studied slant helices in the three dimensional sphere. Also in [3], M. Barros gave the definition of Lancret curve (general helix), the principle normal lines are perpendicular to a fixed direction. Thus a general helix is the special case of a slant helix. It is clear that if $\sigma \equiv 0$ then $\gamma$ is a general helix. Also M. Barros gave a theorem that, a curve $\gamma$ in $\mathbb{H}^3$ is a slant helix if and only if either $\gamma$ is in some unit hyperbolic plane $\mathbb{H}^2 \subset \mathbb{H}^3$ with $\tau \equiv 0$ or $\gamma$ is a helix in $\mathbb{H}^3$.

Thus motivated sufficiently we study general helices in the 3-dimensional hyperbolic space $\mathbb{H}^3(-r)$ and obtain several results corresponding to the rectifying general helix and characterization of rectifying curve in $\mathbb{H}^3(-r)$. Our work is organized as follows: using the Gauss formula and the definition of rectifying curve in $\mathbb{H}^3(-r)$, we find expressions of $T^0_0 \gamma$, $N^0_0 \gamma$, $B^0_0 \gamma$, $T^0_1 \phi_0 \gamma$, $T^0_0 \tau$, $N^0_0 \phi_0 \tau$, $B^0_0 \phi_0 \tau$ etc. Here we take dot product because it gives the geometrical interpretation of curve. Further we obtain the distance function in $\mathbb{H}^3(-r)$ in terms of $\lambda$ and $\mu$, which satisfy some differential equation. We also find distance function in terms of arc length when the rectifying curve lying in the upper half plane. Next we find some characterizations of rectifying curve in $\mathbb{H}^3(-r)$. Finally we give the general equations of the curvature and torsion of a rectifying general helix.

2. Preliminaries

Let $\mathbb{H}^3(p, -r) = \{ x = (x_1, x_2, x_3, x_4) \in \mathbb{R}^4_1 \mid x - p, x - p > -r^2, x_1 > 0 \} \subset \mathbb{R}^4$ be the hyperbolic space with centered at $p \in \mathbb{R}^4$ and radius $r > 0$, where $\mathbb{R}^4_1$ is the four dimensional Lorentzian manifold with flat metric $g = -dx_1^2 + dx_2^2 + dx_3^2 + dx_4^2$. Also we denote $\mathbb{H}^3(0, -r) \equiv \mathbb{H}^3(-r) = \{ x \in \mathbb{R}^4_1 \mid -x_1^2 + x_2^2 + x_3^2 + x_4^2 = -r^2, x_1 > 0 \} \subset \mathbb{R}^4$ and $\mathbb{H}^3(0, -1) \equiv \mathbb{H}^3$.

We know that if $\nabla$ and $\nabla^0$ denote the Levi-Civita connections on $\mathbb{H}^3(-r)$ and $\mathbb{R}^4$ respectively then they are related by the Gauss formula, $\nabla^0_XY = \nabla_XY + \frac{1}{r^2}X, Y > \phi$, where $\phi : \mathbb{H}^3(-r) \to \mathbb{R}^4$ denotes the position vector and $X, Y$ are vector fields tangent to $\mathbb{H}^3(-r)$. Let us consider a unit speed curve $\gamma : I \subset \mathbb{R} \to \mathbb{H}^3(-r)$ and assume that $\gamma$ is not a geodesic curve then we always get $\nabla^0_T^0 \gamma, T^0_0 \gamma, N_0^0 \gamma, B_0^0 \gamma = -\kappa_0 T^0_\gamma, \tau_0 B_\gamma, \tau_\gamma N_\gamma = r \kappa_\gamma N_\gamma$, where two functions $\kappa_\gamma > 0$ and $\tau_\gamma$ are curvature and torsion of the curve $\gamma$. It is also well-known that the *principle normal geodesic* in $\mathbb{H}^3(-r)$ starting at $\gamma(s)$ of the curve $\gamma$ can be defined as the geodesic curve parameterized by $\phi_s(t) = \exp_{\gamma(s)}(tN_\gamma(s)) = \cosh\left(\frac{t}{r}\right) \gamma(s) + r \sinh\left(\frac{t}{r}\right) N_\gamma(s), t \in \mathbb{R}$.

In [8], authors gave two equivalent definitions of rectifying curve in the three dimensional hyperbolic space.

**Definition 2.1.** A unit speed curve $\gamma = \gamma(s)(s \in I)$ in $\mathbb{H}^3(-r)$, with $\kappa_\gamma > 0$, is said to be rectifying curve if there exists a point $p \in \mathbb{H}^3(-r)$ such that $p$ does not belong to $Im(\gamma) \equiv \gamma(I)$ and the geodesics connecting $p$ with $\gamma(s)$ are orthogonal to the principle normal geodesics at $\gamma(s)$, for all $s$.

**Definition 2.2.** The geodesics connecting $p$ with $\gamma(s)$ are tangent to the rectifying plane of $\gamma$ i.e., the planes generated by $\{T^0_\gamma(s), B_\gamma(s)\}$.

Also in [8], two characterization theorems for rectifying curves are given.

**Theorem 2.3.** Let $\gamma = \gamma(s)(s \in I)$ be a unit speed curve in $\mathbb{H}^3(-r)$. Then, $\gamma$ is a rectifying curve if and only if the ratio of torsion and curvature of the curve is given by $\frac{\tau_\gamma(s)}{\kappa_\gamma(s)} = c_1 \sinh\left(\frac{s+s_0}{r}\right) + c_2 \cosh\left(\frac{s+s_0}{r}\right)$, for some constants $c_1, c_2$ and $s_0$, with $1 - c_1^2 + c_2^2 < 0$. 
Theorem 2.4. Let \( p \in H^3(-r) \) and consider a unit speed curve \( V(t) \) in \( S^2(1) \subset T_pH^3(-r) \). Then, for any nonzero function \( \rho(t) \), the curvature \( \kappa_\gamma \) and the speed \( v \) of the curve \( \gamma(t) = \exp_p(\rho(t) V(t)) \), and the geodesic curvature \( \kappa_\nu \) of \( V \) satisfy the inequality \( \frac{v^4 \kappa_\nu^2}{r^2 \sin^2(\rho/r)} \), with the equality sign holding identically if and only if \( \gamma \) is a rectifying curve.

3. Main results

Theorem 3.1. Let \( \gamma : I \subset \mathbb{R} \to \mathbb{H}^3(-r) \) be a unit speed rectifying curve in \( \mathbb{H}^3(-r) \). If \( \{T_\gamma, N_\gamma, B_\gamma\} \) be the Frenet frame along \( \gamma \) and \( \nabla \) and \( \nabla^0 \) denote the Levi-Civita connections on \( \mathbb{H}^3(-r) \) and \( \mathbb{R}^4 \) respectively then by using the Gauss formula the Frenet equations of \( \gamma \) can be written as follows:

\[
T''_\gamma = \kappa_\gamma N_\gamma + \frac{1}{r^2} \gamma, N''_\gamma = -\kappa_\gamma T_\gamma + \kappa_\gamma \psi B_\gamma, B''_\gamma = -\kappa_\gamma N_\gamma,
\]

where \( \kappa_\gamma, \tau_\gamma \) denote the curvature and torsion of \( \gamma \), which satisfy any of the following conditions:

1. \( T''_\phi \cdot T''_\phi = \frac{1}{r^2} (\kappa_\phi N_\phi \cdot \phi + \kappa_\phi N_\phi \cdot \phi + \frac{1}{r^2} \phi \cdot \phi) \),
   \[ N''_\phi \cdot N''_\phi = \lambda_1 \tau_\phi \cdot \phi, \]
   \[ B''_\phi \cdot B''_\phi = 0. \]
2. \( T''_\phi \cdot T''_\phi = \lambda_1 \kappa_\phi \kappa_\gamma + \frac{1}{r^2} (\lambda \kappa_\phi \kappa_\gamma + \phi_\phi \kappa_\gamma) \cdot N_\gamma + \frac{1}{r^2} \phi_\phi \cdot \phi, N''_\phi \cdot N''_\phi = -\lambda_2 \tau_\phi \cdot \phi - \lambda_3 \kappa_\phi \kappa_\gamma - \lambda \kappa_\phi \kappa_\gamma \cdot B''_\phi \cdot B''_\phi = -\lambda_4 \tau_\phi \cdot \phi. \]
3. \( T''_\phi \cdot T''_\phi = \frac{1}{r^2} (\kappa_\phi N_\phi \cdot \phi + \kappa_\phi N_\phi \cdot \phi + \frac{1}{r^2} \phi \cdot \phi) \),
   \[ N''_\phi \cdot N''_\phi = -d_1 \tau_\phi \cdot \phi, \]
   \[ B''_\phi \cdot B''_\phi = 0. \]
4. \( T''_\phi \cdot T''_\phi = \frac{1}{r^2} (\kappa_\phi N_\phi \cdot \phi + \kappa_\phi N_\phi \cdot \phi + \frac{1}{r^2} \phi \cdot \phi) \),
   \[ N''_\phi \cdot N''_\phi = -d_2 \kappa_\phi \kappa_\gamma, \]
   \[ B''_\phi \cdot B''_\phi = 0. \]

where \( \lambda_1, \lambda_2, \lambda_3, \lambda_4, d_1, d_2 \in \mathbb{R} \).

Proof. Let \( \gamma : I \subset \mathbb{R} \to \mathbb{H}^3(-r) \) be a unit speed rectifying curve in \( \mathbb{H}^3(-r) \). If \( \{T_\gamma, N_\gamma, B_\gamma\} \) be the Frenet frame along \( \gamma \) and \( \nabla \) and \( \nabla^0 \) denote the Levi-Civita connections on \( \mathbb{H}^3(-r) \) and \( \mathbb{R}^4 \) respectively then the Frenet equations of \( \gamma \) are

\[
\nabla T_\gamma = \kappa_\gamma N_\gamma, \nabla N_\gamma = -\kappa_\gamma T_\gamma + \kappa_\gamma \psi B_\gamma, \nabla B_\gamma = -\tau_\gamma N_\gamma,
\]

where functions \( \kappa_\gamma > 0 \) and \( \tau_\gamma \) are curvature and torsion of the curve \( \gamma \). After using the Gauss formula in (3.1), we get

\[
\nabla T_\gamma = \kappa_\gamma N_\gamma + \frac{1}{r^2} \gamma, \nabla N_\gamma = -\kappa_\gamma T_\gamma + \tau_\gamma B_\gamma, \nabla B_\gamma = -\tau_\gamma N_\gamma.
\]

Then from ([8], Theorem 3.), using the relation of \( \tau_\gamma \) and \( \kappa_\gamma \) for rectifying curve we obtain,

\[
\nabla T_\gamma = \kappa_\gamma N_\gamma + \frac{1}{r^2} \gamma, \nabla N_\gamma = -\kappa_\gamma T_\gamma + \kappa_\gamma \psi B_\gamma, \nabla B_\gamma = -\kappa_\gamma \psi N_\gamma,
\]

where \( \psi(s) = c_1 f(s) + c_2 g(s) \). Now, we write the equation (3.3) in the following notation

\[
T''_\gamma = \kappa_\gamma N_\gamma + \frac{1}{r^2} \gamma, N''_\gamma = -\kappa_\gamma T_\gamma + \kappa_\gamma \psi B_\gamma, B''_\gamma = -\kappa_\gamma \psi N_\gamma.
\]

Now, using Definition 2.1, let \( \phi_s(t) \) be geodesics connecting \( p \) with \( \gamma(s) \) are orthogonal to the principle normal geodesics \( \bar{\gamma} \) at \( \gamma(s) \), for all \( s \). Then we get,

\[
T''_\phi_(t) = \kappa_\phi_(t) N_\phi_(t) + \frac{1}{r^2} \phi_(t),
\]

\[
N''_\phi_(t) = -\kappa_\phi_(t) T_\phi_(t) + \tau_\phi_(t) B_\phi_(t),
\]

\[
B''_\phi_(t) = -\tau_\phi_(t) N_\phi_(t),
\]

where \( \phi_1, \phi_2, \phi_3, \phi_4 \in \mathbb{R} \).
and

\[
T^{\phi'} = \kappa_2 N_\gamma + \frac{1}{r^2} \bar{\gamma},
\]
\[
N^{\phi'} = -\kappa_2 T_\gamma + \tau_2 B_\gamma,
\]
\[
B^{\phi'} = -\tau_2 N_\gamma.
\]

Now for the case of rectifying curve, \(\phi_s(t)\) and \(\bar{\gamma}(s)\) are orthogonal at \(\gamma(s)\) for all \(s\) i.e.,
\[
T_{\phi_s(t)} \cdot T_{\bar{\gamma}} = 0
\]
and we get two cases corresponding to the Frenet frame of the curves \(\phi_s\) and \(\bar{\gamma}\).

**Case 1.**

Then using Condition (i) in the equations (3.5) and (3.6), we get

\[
T^{\phi'} \cdot T^{\bar{\phi'}} = \frac{1}{r^2} (\kappa_\phi N_\phi \cdot \bar{\gamma} + \kappa_\bar{\phi} \phi_s \cdot N_\bar{\gamma} + \frac{1}{r^2} \phi_s \cdot \bar{\gamma}),
\]
\[
N^{\phi'} \cdot N^{\bar{\phi'}} = \lambda_1 T_{\phi_s(t)} \cdot T_{\bar{\gamma}} = \lambda_1 \tau_{\phi_s(t)} \cdot T_{\bar{\gamma}}, B^{\phi'} \cdot B^{\bar{\phi'}} = 0,
\]
where \(B_{\phi_s} = \lambda_1 B_{\bar{\gamma}}\). By using Condition (ii) in the equations (3.5) and (3.6), we obtain

\[
T^{\phi'} \cdot T^{\bar{\phi'}} = \frac{1}{r^2} (\kappa_\phi N_\phi \cdot \bar{\gamma} + \kappa_\bar{\phi} \phi_s \cdot N_\bar{\gamma} + \frac{1}{r^2} \phi_s \cdot \bar{\gamma})
\]
\[
N^{\phi'} \cdot N^{\bar{\phi'}} = -\lambda_2 T_{\phi_s(t)} \cdot T_{\bar{\gamma}} - \lambda_3 T_{\phi_s(t)} \cdot B_{\bar{\gamma}} = -\lambda_2 \tau_{\phi_s(t)} \cdot T_{\bar{\gamma}} - \lambda_3 \kappa_{\phi_s(t)} \cdot B_{\bar{\gamma}},
\]
\[
B^{\phi'} \cdot B^{\bar{\phi'}} = \lambda_4 \tau_{\phi_s(t)} \cdot T_{\bar{\gamma}},
\]
where \(B_{\phi_s} = \lambda_2 T_{\bar{\gamma}}, T_{\phi_s} = \lambda_3 B_{\bar{\gamma}}\) and \(N_{\phi_s} = \lambda_4 N_{\bar{\gamma}}\). Now we know that \(T_\gamma\) can be written as
\[
T_\gamma = c_1 T_\gamma + c_2 N_\gamma + c_3 B_\gamma,
\]
and \(T_\gamma = c_3' T_\phi + c_2' N_\phi + c_1' B_\phi\). Also we know that \(T_\gamma, T_{\phi_s} = 1\), therefore after using Condition (ii), we get

\[
c_1 c_3' T_{\phi_s} + c_2 c_2' N_{\phi_s} + c_3 c_1' B_{\phi_s} + c_4' T_{\phi_s} = 1,
\]
\[
\Rightarrow c_1 c_3' \lambda_2 + c_2 c_2' \lambda_4 + c_3 c_1' \lambda_3 = 1.
\]
\[
\Rightarrow c_1 c_3' \lambda_2 + c_3 c_1' \lambda_3 = 1 - c_2 c_2' \lambda_3.
\]

where we consider \(\lambda_4 = d_3 \in \mathbb{R}\). Thus we get

\[
c\lambda_2 + d\lambda_3 = n,
\]
where \(c = c_1 c_3', d = c_3 c_1', n = 1 - c_2 c_2' d_3\).
On the other hand we can write $N_\gamma = b_1 T_{\phi_s} + b_2 N_{\phi_s} + b_3 B_{\phi_s}$ and $N_{\phi_s} = b'_1 T_\gamma + b'_2 N_\gamma + b'_3 B_\gamma$. Now, taking the dot product of $N_\gamma$ and $N_{\phi_s}$, and then using Condition (ii), we get $b_3 b'_1 \lambda_2 + b_1 b'_3 \lambda_3 = (1 - b_2 b'_2) d_3 = m$, which implies

$$a \lambda_2 + b \lambda_3 = m,$$

where $a = b_3 b'_1$, $b = b_1 b'_3$, $m = (1 - b_2 b'_2) d_3$ and $c_1, c_2, c_3, c'_1, c'_2, c'_3, b_1, b_2, b'_1, b'_2, b'_3, a, b, c, d, m, n, \lambda_1, \lambda_2, \lambda_3, \lambda_4 \in \mathbb{R}$.

On solving the equations (3.7) and (3.8), we get $\lambda_2 = \frac{d m - b b'_2}{a d - c b'_2}, \lambda_3 = \frac{c m - a b_2}{c b - a d}$. Similarly, using Condition (i), $\lambda_1$ can also be calculated.

Case 2.

Then using Condition (i) in the equations (3.5) and (3.6), we get

$$T^{o'}_{\phi_s}.T^{o'}_\gamma \gamma = \frac{1}{r^2}(\kappa_{\phi_s} N_{\phi_s} \gamma + \kappa_\gamma \phi_s \gamma + \frac{1}{r^2} \phi_s \gamma),$$

$$N^{o'}_{\phi_s} N^{o'}_\gamma = -\tau_{\phi_s} \kappa_\gamma T_\gamma B_{\phi_s} = -d_1 \tau_{\phi_s} \kappa_\gamma B^{o'}_{\phi_s(t)} B^{o'}_\gamma = 0,$$

where $B_{\phi_s} = d_1 T_\gamma$. By using Condition (ii) in the equations (3.5) and (3.6), we get

$$T^{o'}_{\phi_s}.T^{o'}_\gamma \gamma = \frac{1}{r^2}(\kappa_{\phi_s} N_{\phi_s} \gamma + \kappa_\gamma \phi_s \gamma + \frac{1}{r^2} \phi_s \gamma),$$

$$N^{o'}_{\phi_s} N^{o'}_\gamma = -\kappa_{\phi_s} \tau_\gamma T_{\phi_s} B_\gamma = -d_2 \kappa_{\phi_s} \tau_\gamma B^{o'}_{\phi_s(t)} B^{o'}_\gamma = 0,$$

where $T_{\phi_s} = d_2 T_\gamma$. Then from above procedure we can find the values of $d_1, d_2 \in \mathbb{R}$. Thus, we obtain the required results.

\textbf{Theorem 3.2.} Let $\gamma = \gamma(s)$ be a unit speed rectifying curve in $\mathbb{H}^3(-r)$. Then the distance function $\rho = \|\gamma\|$ satisfies $\rho^2 = -\lambda^2 + \mu^2$, where $\lambda$ and $\mu$ satisfy the equation $(1 - \lambda) a T_\gamma - (b - b\lambda' + \mu') B_\gamma + \frac{\lambda}{r^2} = \lambda T^{o'}_\gamma + \mu B^{o'}_\gamma$ and $a, b \in \mathbb{R}$.

\textbf{Proof.} Let $\gamma = \gamma(s)$ be a unit speed rectifying curve in $\mathbb{H}^3(-r)$. Then position vector $\gamma$ of a curve satisfies the equation

$$\gamma(s) = \lambda(s) T_\gamma(s) + \mu(s) B_\gamma(s),$$

where $\lambda(s)$ and $\mu(s)$ are differential functions. Now, differentiating the equation (3.9) with respect to $s$ and using Frenet equations, we get $T_\gamma(s) = \lambda'(s) T_\gamma(s) + \lambda(s) (T^{o'}_\gamma - \frac{1}{r^2} \gamma) + \mu'(s) B_\gamma(s) + \mu B^{o'}_\gamma$, which implies

$$(1 - \lambda) T_\gamma - \mu' B_\gamma - \lambda T^{o'}_\gamma - \mu B^{o'}_\gamma + \frac{\lambda \gamma}{r^2} = 0.$$
Then using Definition 2.1 of rectifying curve in $\mathbb{H}^3(-r)$, $T_\gamma$ can be written in the form, $T_\gamma = aT_\gamma - bB_\gamma$, where $\gamma$ is the geodesics connecting $p$ with $\gamma(s)$ are tangent to the rectifying plane of $\gamma$ i.e., the planes generated by $\{T_\gamma(s), B_\gamma(s)\}$. Therefore the equation (3.10) can be rewritten as

$$\left(1 - \lambda^\prime\right) aT_\gamma - (b - b\lambda + \mu^\prime)B_\gamma + \frac{\lambda_\gamma}{t^2} = \lambda T_\gamma^\prime + \mu B_\gamma^\prime. \quad (3.11)$$

Also from the equation (3.9), it is clear that the distance function $\rho^2 = ||\gamma||^2 = |g(\gamma, \gamma)| = -\lambda^2 + \mu^2$, where $\lambda$ and $\mu$ satisfy the equation (3.11). Thus the proof is completed. □

**Theorem 3.3.** Let $\gamma = \gamma(s)$ be a unit speed rectifying curve in $\mathbb{H}^3(-r)$, lies in the upper half plane $U^2$. Then the distance function $\rho = ||\gamma||$ satisfies $\rho^2 = |a^2 + bs + c|$ or $\rho^2 = 1 + f^2(s)$, where $f(s) = c_1 \sinh(\frac{t}{r}) + c_2 \cosh(\frac{t}{r})$ and $a, b, c \in \mathbb{R}$.

**Proof.** Let $\gamma = \gamma(s)$ be a unit speed rectifying curve in $\mathbb{H}^3(-r)$. Now, we know that

$$\gamma(s) = \lambda(s)T_\gamma(s) + \mu(s)B_\gamma(s), \quad (3.12)$$

where $\lambda(s)$ and $\mu(s)$ are differentiable functions.

Now we know that $T_\gamma(s)$ and $B_\gamma(s)$ are generating a plane, let it be a subset of upper half plane. Therefore $\gamma(s) = (\lambda(s), \mu(s))$ be a curve in $U^2$. Then after differentiating the equation (3.12) and using Frenet formulas for $\gamma$, we obtain $(1 - \lambda^\prime)T_\gamma + (\mu \tau_\gamma - \lambda \kappa_\gamma)N_\gamma - \mu^\prime B_\gamma = 0$, which implies

$$\lambda^\prime = 1, \mu^\prime = 0, \mu \tau_\gamma - \lambda \kappa_\gamma = 0. \quad (3.13)$$

Therefore $\lambda(s) = s + d_1$, $\mu(s) = d_2$, $\mu(s)T_\gamma(s) = \lambda(s)K_\gamma(s)$. Thus the distance function $\rho^2 = |g(\gamma, \gamma)| = |\lambda^2 + \mu^2| = |\frac{(s + d_1)^2 + d_2^2}{d_2^2}| = |a^2 + bs + c|$, where $a = \frac{1}{d_2^2}$, $b = \frac{2d_1}{d_2}$, $c = \frac{d_1^2 + d_2^2}{d_2^2}$, $d_1, d_2 \in \mathbb{R}$. Also from the equation (3.13), we get $\frac{\lambda(s)}{\mu(s)} = \frac{\kappa_\gamma}{\kappa_\gamma}$. Now we know that $\kappa_\gamma = c_1 \sinh(\frac{t}{r}) + c_2 \cosh(\frac{t}{r}) = f(s)$, from [8]. Hence $\frac{\lambda}{\mu} = f$. Therefore the distance function, $\rho^2 = |g(\gamma, \gamma)| = |\lambda^2 + \mu^2| = |1 + f^2|$. Thus, $\rho^2 = 1 + f^2(s)$. This proves the theorem. □

**Note.** Now, we know that $\gamma(s) = \lambda(s)T_\gamma(s) + \mu(s)B_\gamma(s)$, where $\lambda(s)$ and $\mu(s)$ are differential functions.

(i) Therefore, $g(\gamma, T_\gamma) = \lambda(s) = s + d_1$. This is the tangential component of $\gamma(s)$.

(ii) The normal component of $\gamma(s) = \mu(s)B_\gamma(s)$. Therefore, $||\gamma|| = d_2 \neq 0$ i.e., the normal component of $\gamma(s)$ has a constant length.

(iii) The binormal component of $\gamma(s)$, $g(\gamma, B_\gamma(s)) = \mu(s) = d_2$, is constant.

**Theorem 3.4.** Let $\psi(t)$ be a unit speed curve in $\mathbb{H}^3$ and $\gamma$ be a rectifying curve in $\mathbb{H}^3(-r)$ with upper half plane as rectifying plane then it has up to a parametrization given by $\gamma(t) = \psi(t)T_\gamma(t), \text{ or } \gamma(t) = \psi(t)B_\gamma(t)$.

**Proof.** Now from Theorem 3.3, we know that $\rho^2 = a^2 + bs + c$ or $\rho^2 = 1 + f^2(s)$. Let $\rho^2 = |\frac{(s + d_1)^2 + d_2^2}{d_2^2}|$, we apply a translation to $s$, such that $\rho^2 = a^2 + 1$. Now we define a curve $\psi(t)$ in $\mathbb{H}^3$ by $\psi(s) = \frac{\gamma(s)}{\rho(s)}$, $\Rightarrow \gamma(s) = \psi(s) \sqrt{a^2 + 1}$. Then differentiating with respect to $s$, we get

$$T_{\gamma}(s) = \psi(s) \frac{as}{\sqrt{a^2 + 1}} + \psi(s) \sqrt{a^2 + 1}. \quad (3.14)$$

Since, $g(\psi, \psi) = 1$, it follows that $g(\psi, \psi) = 0$. Therefore from the equation (3.14), we obtain $1 = g(T_{\gamma}(s)) = g(\psi(s) \sqrt{a^2 + 1} + \frac{as^2}{a^2 + 1})$, which implies

$$g(\psi, \psi^\prime) = \frac{as^2(1 - a) + 1}{(a^2 + 1)^2}. \quad (3.15)$$
Thus, $\|\psi'(s)\| = \frac{\sqrt{a^2(1-n)+1}}{a}$.

Let $t = \int_0^a \|\psi'(u)\| du = \int_0^a \frac{\sqrt{a^2(1-n)+1}}{a} du = \varphi(s)$. Therefore $t = \varphi(s)$ or $s = \varphi^{-1}(t)$. Put this into $\gamma(s) = \psi(s)\sqrt{a^2+1}$, we get $\gamma(t) = \psi(t)\eta(\varphi^{-1}(t)) = \psi(t)\phi(t)$, where $\eta(s) = \sqrt{a^2+1}, \phi = \eta \circ \varphi^{-1}$. Hence $\gamma(t) = \psi(t)\phi(t)$. Similarly if we take $\rho^2 = 1 + f^2(s)$ then up to parametrization for $\gamma$ is in the form $\psi(t)\phi(t)$, which completes the proof. □

**Theorem 3.5.** Let $\gamma = \gamma(s)$ be a unit speed rectifying curve in $\mathbb{H}^3(-r)$. Then $T_1$ can be written in the form, $T_1 = \alpha(s)N_1 + \beta(s)B_1$, where $\alpha(s) = \frac{\lambda\kappa_1 - \mu_2\gamma}{a - a\lambda}$ and $a, b \in \mathbb{R}$.

**Proof.** Let us consider $\gamma = \gamma(s)$ be a unit speed rectifying curve in $\mathbb{H}^3(-r)$. Then position vector $\gamma$ of a curve satisfies the equation,

$$\gamma(s) = \lambda(s)T_1(s) + \mu(s)B_1(s),$$

(3.16)

where $\lambda(s)$ and $\mu(s)$ are differentiable functions. On differentiating the equation (3.16), we obtain $T_1 = \lambda' T_1 + \lambda T_1 + \lambda\kappa_1 N_1 - \lambda\tau_1 N_2$, which implies

$$\Rightarrow (1 - \lambda')T_1 + (\mu\tau_1 - \lambda\kappa_1)N_2 = -\lambda' B_1 = 0.$$

(3.17)

Since $\gamma = \gamma(s)$ is a unit speed rectifying curve in $\mathbb{H}^3(-r)$ therefore $T_1 = aT_1 - bB_1$, where $a, b \in \mathbb{R}$. Thus from the equation (3.17), we get $(a - a\lambda)T_1 + (\mu\tau_1 - \lambda\kappa_1)N_2 = -b(b + \mu')B_1 = 0$, which gives

$$T_1 = \alpha(s)N_1 + \beta(s)B_1,$$

(3.18)

where $\alpha(s) = \frac{\lambda\kappa_1 - \mu_2\gamma}{a - a\lambda}$ and $\beta(s) = \frac{b - b\lambda + \mu'}{a - a\lambda}$, $a, b \in \mathbb{R}$. This completes the proof. □

**Theorem 3.6.** Let $\gamma = \gamma(s)$ be a unit speed curve in $\mathbb{H}^3(-r)$. Then $\gamma$ is a rectifying general helix if and only if the torsion and curvature of the curve are given by

(i) $\tau_2^2(s) = \sinh^2(\frac{s}{r}) \cos^2\left(\frac{s + s_0}{r}\right) [A \tan^2(\frac{s + s_0}{r}) + C \tan(\frac{s + s_0}{r})],

where $A = \frac{c_1^2 c_2^2 t^2}{v^4}$, $B = \frac{c_1^2 c_2^2 t^2}{v^4}$, $C = \frac{2c_1 c_2^2 x^2}{v^4}$.

(ii) $\kappa_2^2(s) = \sin^2(\frac{s}{r})$, if $A = c_1^2$, $B = c_2^2$, $C = 2c_1 c_2$.

**Proof.** By using Theorem 2.3 and Theorem 2.4, we obtain

$$\tau_2^2(s) = \frac{c_1^2 r^2 \sinh(\frac{s}{r})}{v^4} \left(c_1 \sinh(\frac{s + s_0}{r}) + c_2 \cosh(\frac{s + s_0}{r})\right)^2,$$

which implies

$$\tau_2^2(s) = A \sinh^2(\frac{s}{r}) \sinh^2\left(\frac{s + s_0}{r}\right) + C \sinh^2(\frac{s}{r}) \sin(\frac{s + s_0}{r}) \cosh(\frac{s + s_0}{r}),$$

$$+ B \sinh^2(\frac{s}{r}) \cosh^2(\frac{s + s_0}{r}),$$

where $A = \frac{c_1^2 c_2^2 t^2}{v^4}$, $B = \frac{c_1^2 c_2^2 t^2}{v^4}$, $C = \frac{2c_1 c_2^2 x^2}{v^4}$. Thus

$$\tau_2^2(s) = \sinh^2(\frac{s}{r}) \cosh^2\left(\frac{s + s_0}{r}\right) [A \sinh^2(\frac{s + s_0}{r}) \cosh^2(\frac{s + s_0}{r}) + C \sin(\frac{s + s_0}{r}) \cosh^2(\frac{s + s_0}{r})] + B],$$

$$\Rightarrow \tau_2^2(s) = \sinh^2(\frac{s}{r}) \cosh^2(\frac{s + s_0}{r}) [A \tan^2(\frac{s + s_0}{r}) + C \tan(\frac{s + s_0}{r})] + B].$$

Also, again by using Theorem 2.3 and Theorem 2.4, we obtain

$$\kappa_2^2(s) = \frac{\tau_2^2(s)}{(c_1 \sinh(\frac{s + s_0}{r}) + c_2 \cosh(\frac{s + s_0}{r}))^2}.$$
\[ \Rightarrow \kappa_\gamma^2(s) = \frac{\sinh^2(\rho/r) \cosh^2(s + s_0)[A \tanh^2(s + s_0) + C \tanh(s + s_0) + B]}{\cosh^2(s + s_0)[c_1^2 \tanh^2(s + s_0) + 2c_1c_2 \tanh(s + s_0) + c_2^2]}. \]

Thus \( \kappa_\gamma^2(s) = \sinh^2(\rho/r) \) if \( A = c_1^2, B = c_2^2 \) and \( C = 2c_1c_2 \), which concludes the theorem. \( \square \)

**Corollary 3.7.** The geodesic curvature \( \kappa_V \) of rectifying general helix in \( H^3(-r) \) is given by \( \kappa_V = v^2/r \), where \( v \) is the speed of rectifying general helix.

**Proof.** The proof is obtained from Theorem 3.6. \( \square \)

**Theorem 3.8.** A curve \( \gamma(s) = \exp(\rho(s)V(s)) \) in \( H^3(-r) \) is a rectifying general helix with geodesic curvature \( \kappa_V(t) = c(\cos^2(t + t_0) - a^2)^{-3/2} \) and torsion \( \tau(s) = d_1 \sinh((s + s_0)/r) + d_2 \cosh((s + s_0)/r) \) then its curvature \( \kappa_\gamma \) is of the form \( \kappa_\gamma = \frac{d_1}{c_1} \) if and only if

\[
\begin{vmatrix}
  c_1 & c_2 \\
  d_1 & d_2
\end{vmatrix} = 0.
\]

**Proof.** By using Corollary 9 of [8], we obtain

\[
\kappa_\gamma = \frac{d_1 \sinh((s + s_0)/r) + d_2 \cosh((s + s_0)/r)}{c_1 \sinh(s + s_0) + c_2 \cosh(s + s_0)},
\]

\[
\Rightarrow \kappa_\gamma = \frac{d_1(\tanh(s + s_0)/r) + A}{c_1(\tanh(s + s_0)/r) + B},
\]

where \( A = \frac{d_2}{d_1} \) and \( B = \frac{c_2}{c_1} \).

Thus \( \kappa_\gamma = \frac{d_1}{c_1} \) if and only if \( A = B \) i.e.

\[
\begin{vmatrix}
  c_1 & c_2 \\
  d_1 & d_2
\end{vmatrix} = 0.
\]

\( \square \)
