Distributed Constrained Optimization by Consensus-Based Primal-Dual Perturbation Method

Tsung-Hui Chang⋆, Member, IEEE, Angelia Nedić†, Member, IEEE, and Anna Scaglione‡, Fellow, IEEE

Revised, April 2013

Abstract

Various distributed optimization methods have been developed for solving problems which have simple local constraint sets and whose objective function is the sum of local cost functions of distributed agents in a network. Motivated by emerging applications in smart grid and distributed sparse regression, this paper studies distributed optimization methods for solving general problems which have a coupled global cost function and have inequality constraints. We consider a network scenario where each agent has no global knowledge and can access only its local mapping and constraint functions. To solve this problem in a distributed manner, we propose a consensus-based distributed primal-dual perturbation (PDP) algorithm. In the algorithm, agents employ the average consensus technique to estimate the global cost and constraint functions via exchanging messages with neighbors, and meanwhile use a local primal-dual perturbed subgradient method to approach a global optimum. The proposed PDP method not only can handle smooth inequality constraints but also non-smooth constraints such as some sparsity promoting constraints arising in sparse optimization. We prove that the proposed PDP algorithm converges to an optimal primal-dual solution of the original problem, under standard problem and network assumptions. Numerical examples illustrating the performance of the proposed algorithm for a sparse regression problem and a demand response control problem in smart grid are also presented.

resource allocation problems in peer-to-peer/multi-cellular communication networks [3], [4], and distributed learning and regression problems in control [5] and machine learning [6]–[8], to name a few. In these applications, rather than pooling together all the relevant parameters that define the optimization problem, distributed agents, which have access to a local subset of such parameters, collaborate with each other to minimize a global cost function, subject to local variable constraints. Specifically, since it is not always efficient for the agents to exchange across the network the local cost and constraint functions, owing to the large size of network, time-varying network topology, energy constraints and/or privacy issues, distributed optimization methods that utilize only local information and messages exchanged between connecting neighbors have been of great interest; see [9]–[16] and references therein.

**Contributions:** Different from the existing works [9]–[14] where the local variable constraints are usually simple (in the sense that they can be handled via simple projection) and independent among agents, in this paper, we consider a problem formulation that has a general set of convex inequality constraints that couple all the agents’ optimization variables. In addition, similar to [17], the considered problem has a global (non-separable) convex cost function that is a function of the sum of local mapping functions of the local optimization variables. Such a problem formulation appears, for example, in the classical regression problems which have a wide range of applications. In addition, the considered formulation also arises in the demand response control and power flow control problems in the emerging smart grid systems [18]–[20]. More discussions about applications are presented in Section II-B.

In this paper, we assume that each agent knows only the local mapping function and local constraint function. To solve this problem in a distributed fashion, in this paper, we develop a novel distributed consensus-based primal-dual perturbation (PDP) algorithm, which combines the ideas of the primal-dual perturbed (sub-)gradient method [21], [22] and the average consensus techniques [10], [23], [24]. In each iteration of the proposed algorithm, agents exchange their local estimates of the global cost and constraint functions with their neighbors, followed by performing one-step of primal-dual variable (sub-)gradient update. Instead of using the primal-dual iterates computed at the preceding iteration as in most of the existing primal-dual subgradient based methods [15], [16], the (sub-)gradients in the proposed distributed PDP algorithm are computed based on some perturbation points which can be efficiently computed using the messages exchanged from neighbors. In particular, we provide two efficient ways to compute the

DRAFT September 9, 2013
perturbation points that can respectively handle the smooth and non-smooth constraint functions. More importantly, we build convergence analysis results showing that the proposed distributed PDP algorithm ensures a strong convergence of the local primal-dual iterates to a global optimal primal-dual solution of the considered problem. The proposed algorithm is applied to a distributed sparse regression problem and a distributed demand response control problem in smart grid. Numerical results for the two applications are presented to demonstrate the effectiveness of the proposed algorithm.

**Related works:** Distributed dual subgradient method (e.g., dual decomposition) [25] is a popular approach to solving a problem with coupled inequality constraints in a distributed manner. However, given the dual variables, this method requires the agents to globally solve the local subproblems, which may require considerable computational efforts if the local cost and constraint functions have some complex structure. Consensus-based distributed primal-dual (PD) subgradient methods have been developed recently in [15], [16] for solving a problem with an objective function which is the sum of local convex cost functions, and with global convex inequality constraints. In addition to having a different cost function from our problem formulation, the works in [15], [16] assumed that all the agents in the network have global knowledge of the inequality constraint function; the two are in sharp contrast to our formulation where a non-separable objective function is considered and each agent can access only its local constraint function. Moreover, these works adopted the conventional PD subgradient updates [26], [27] without perturbation. Numerical results will show that these methods do not perform as well as the proposed algorithm with perturbation. Another recent development is the Bregman-distance based PD subgradient method proposed in [28] for solving an epigraph formulation of a min-max problem. The method in [28], however, assumes that the Lagrangian function has a unique saddle point, in order to guarantee the convergence of the primal-dual iterates. In contrast, our proposed algorithm, which uses the perturbed subgradients, does not require such assumption.

**Synopsis:** Section II presents the problem formulation, applications, and a brief review of the centralized PD subgradient methods. Section III presents the proposed distributed consensus-based PDP algorithm. The assumptions and convergence analysis results are given in Section IV. Numerical results are presented in Section V. Finally, the conclusions and discussion of future extensions are drawn in Section VI.
II. Problem Formulation, Applications and Brief Review

A. Problem Formulation

We consider a network with \( N \) agents, denoted by \( V = \{1, \ldots, N\} \). We assume that, for all \( i = 1, \ldots, N \), each agent \( i \) has a local decision variable \( x_i \in \mathbb{R}^K \), a local constraint set \( X_i \subseteq \mathbb{R}^K \), and a local mapping function \( f_i : \mathbb{R}^K \to \mathbb{R}^M \), in which \( f_i = (f_{i1}, \ldots, f_{iM})^T \) with each \( f_{im} : \mathbb{R}^K \to \mathbb{R} \) being continuous. The network cost function is given by

\[
\bar{F}(x_1, \ldots, x_N) \triangleq \mathcal{F}\left(\sum_{i=1}^{N} f_i(x_i)\right),
\]

(1)

where \( \mathcal{F} : \mathbb{R}^M \to \mathbb{R} \) and \( \bar{F} : \mathbb{R}^{NK} \to \mathbb{R} \) are continuous. In addition, the agents are subject to a global inequality constraint \( \sum_{i=1}^{N} g_i(x_i) \preceq 0 \), where \( g_i : \mathbb{R}^K \to \mathbb{R}^P \) are continuous mappings for all \( i = 1, \ldots, N \); specifically, \( g_i = (g_{i1}, \ldots, g_{iP})^T \), with each \( g_{ip} : \mathbb{R}^K \to \mathbb{R} \) being continuous. The vector inequality \( \sum_{i=1}^{N} g_i(x_i) \preceq 0 \) is understood coordinate-wise.

We assume that each agent \( i \) can access \( \mathcal{F}(\cdot), f_i(\cdot), g_i(\cdot) \) and \( X_i \) only, for all \( i = 1, \ldots, N \). Under this local knowledge constraint, the agents seek to cooperate with each other to minimize the total network cost \( \bar{F}(x_1, \ldots, x_N) \) (or maximize the network utility \( -\bar{F}(x_1, \ldots, x_N) \)). Mathematically, the optimization problem can be formulated as follows

\[
\min_{x_i \in X_i, i = 1, \ldots, N} \bar{F}(x_1, \ldots, x_N) \quad \text{s.t.} \quad \sum_{i=1}^{N} g_i(x_i) \preceq 0.
\]

(2)

The goal of this paper is to develop a distributed algorithm for solving (2) with each agent communicating with their neighbors only.

B. Application to Smart Grid Control

In this subsection, we discuss some smart grid control problems where the problem formulation (2) may arise. Consider a power grid system where a retailer (e.g., the utility company) bids electricity from the power market and serves a residential/industrial neighborhood with \( N \) customers. In addition to paying for its market bid, the retailer has to pay additional cost if there is a deviation between the bid purchased in earlier market settlements and the real-time aggregate load of the customers. Any demand excess or shortfall results in a cost for the retailer.

\[\text{1Here, without loss of generality, we assume that all the agents have the same variable dimension } K. \text{ The proposed algorithm and analysis can be easily generalized to the case with different variable dimensions.}\]
that mirrors the effort to maintain the power balance. In the smart grid, thanks to the advances in communication and sensory technologies, it is envisioned that the retailer can observe the load of customers and can even control the power usage of some of the appliances (e.g., controlling the charging rate of electrical vehicles and turning ON/OFF air conditioning systems), which is known as the demand side management (DSM); see [29] for a recent review.

We let \( p_t, t = 1, \ldots, T \), be the power bids over a time horizon of length \( T \), and let \( \psi_{i,t}(x_i) \), \( t = 1, \ldots, T \), be the load profile of customer \( i \), where \( x_i \in \mathbb{R}^K \) contains some control variables. The structures of \( \psi_{i,t} \) and \( x_i \) depend on the appliance load model. As mentioned, the retailer aims to minimize the cost caused by power imbalance, e.g., [18], [19], [29]

\[
\min_{x_1 \in X_1, \ldots, x_K \in X_K} \left[ C_p \left( \sum_{i=1}^{N} \psi_i(x_i) - p \right)^+ + C_s \left( p - \sum_{i=1}^{N} \psi_i(x_i) \right)^+ \right] \tag{3}
\]

where \((x)^+ = \max\{x, 0\}\), \( X_i \) denotes the local control constraint set and \( C_p, C_s : \mathbb{R}^T \to \mathbb{R} \) denote the cost functions due to insufficient and excessive power bids, respectively. Moreover, let \( p = (p_1, \ldots, p_T)^T \) and \( \psi_i = (\psi_{i,1}, \ldots, \psi_{i,T})^T \). By defining \( z = (\sum_{i=1}^{N} \psi_i(x_i) - p)^+ \) and assuming that \( C_p \) is monotonically increasing, one can write (3) as

\[
\min_{x_1 \in X_1, \ldots, x_K \in X_K} C_p[z] + C_s \left[ z - \sum_{i=1}^{N} \psi_i(x_i) + p \right] \tag{4}
\]

s.t. \( \sum_{i=1}^{N} \psi_i(x_i) - p - z \preceq 0 \),

which belongs to the considered formulation in (2). Similar problem formulations also arise in the microgrid control problems [20], [30] where the microgrid controller requires not only to control the loads but also to control the local power generation and local power storage (i.e., power flow control), in order to maintain power balancing within the microgrid; see [30] for detailed formulations.

Distributed control methods are appealing to the smart grid application since all the agents are identical and failure of one agent would not have significant impact on the performance of the whole system [31]. Besides, it also spares the retailer/microgrid controller from the task of collecting real-time load information from the customers, which not only infringes on the customer’s privacy but also is not easy for a large scale neighborhood. In Section V, the proposed distributed algorithm will be applied to a DSM problem as in (4).
In addition to the smart grid applications, problem (2) incorporates the important regression problems which widely appear in control [5], machine learning [6], [7], data mining [32], [33] and imaging processing [7] applications. Formulation (2) also encompasses the network flow control problems [34]; see [35] for an example which considered maximizing the network lifetime. The proposed distributed algorithm therefore can be applied to these problem as well. For example, in [36], we have shown how the proposed distributed algorithm can be applied to handle a distributed sparse regression problem.

C. Centralized PD Subgradient Method

Let us consider the following Lagrange dual problem of (2):

\[
\max_{\lambda \succeq 0} \left\{ \min_{x \in X} \mathcal{L}(x, \lambda) \right\},
\]

where \( x = (x_1^T, \ldots, x_N^T)^T, X = X_1 \times \cdots \times X_N, \lambda \in \mathbb{R}_+^P \) (\( \mathbb{R}_+^P \) is the non-negative orthant in \( \mathbb{R}^P \)) is the dual variable associated with the inequality constraint \( \sum_{i=1}^N g_i(x_i) \preceq 0 \), and \( \mathcal{L}: \mathbb{R}^{NK} \times \mathbb{R}_+^P \to \mathbb{R} \) is the Lagrangian function, given by

\[
\mathcal{L}(x, \lambda) = \bar{F}(x_1, \ldots, x_N) + \lambda^T \left( \sum_{i=1}^N g_i(x_i) \right).
\]

We assume that strong duality holds for problem (2) [37]:

Assumption 1 Problem (2) is a convex problem and Slater’s condition holds, i.e., there is an \((\bar{x}_1, \ldots, \bar{x}_N)\) that lies in the relative interior of \( X_1 \times \cdots \times X_N \) such that \( \sum_{i=1}^N g_i(\bar{x}_i) < 0 \).

Under such condition, one is able to handle (2) by solving its dual (5). A classical approach is the dual subgradient method [38]. One limitation of such method is that the inner problem needs to be globally solved at each iteration, which, however, is not always easy, especially when \( f_i(x_i) \) and \( g_i(x_i) \) are complex or when the problem is large scale. Another approach is the primal-dual (PD) subgradient method [26], [39] which handles the inner problem inexactly. More precisely, at iteration \( k \), the PD subgradient method performs

\[
x^{(k)} = \mathcal{P}_X(x^{(k-1)} - a_k \mathcal{L}_x(x^{(k-1)}, \lambda^{(k-1)})), \tag{7a}
\]

\[
\lambda^{(k)} = (\lambda^{(k-1)} + a_k \mathcal{L}_\lambda(x^{(k-1)}, \lambda^{(k-1)}))^+, \tag{7b}
\]

This requires that \( X \) is closed and convex, \( \bar{F}(x) \) is convex in \( x \) and each \( g_i(x_i) \) is convex in \( x_i \). Further detailed assumptions on functions \( \bar{F}, F, f_i, \) and \( g_i \) and constraint set \( X \) are given in Assumption 2 and Assumption 3 in Section III.
where $P: \mathbb{R}^{NK} \rightarrow \mathcal{X}$ is a projection function, $a_k > 0$ is the step size, and

$$
\mathcal{L}_x(x^{(k)}, \lambda^{(k)}) \triangleq \begin{bmatrix}
\nabla f_1^T(x^{(k)}) \nabla F(\sum_{i=1}^N f_i(x^{(k)})) + \nabla g_1^T(x^{(k)})\lambda^{(k)} \\
\vdots \\
\nabla f_N^T(x^{(k)}) \nabla F(\sum_{i=1}^N f_i(x^{(k)})) + \nabla g_N^T(x^{(k)})\lambda^{(k)}
\end{bmatrix}, \tag{8a}
$$

$$
\mathcal{L}_\lambda(x^{(k)}, \lambda^{(k)}) \triangleq \sum_{i=1}^N g_i(x^{(k)}), \tag{8b}
$$

represent the subgradients of $\mathcal{L}$ at $(x^{(k)}, \lambda^{(k)})$ with respect to $x$ and $\lambda$, respectively. Each $\nabla g_i(x^{(k)})$ is a $P \times K$ Jacobian matrix with rows equal to the subgradients $\nabla g_{ip}(x_i)$, $p = 1, \ldots, P$ (gradients if they are continuously differentiable), and each $\nabla f_i(x^{(k)})$ is a $M \times K$ Jacobian matrix with rows containing the gradients $\nabla f_{im}^T(x_i)$, $m = 1, \ldots, M$.

The idea behind the PD subgradient method lies in the well-known saddle-point relation:

**Theorem 1** (Saddle-Point Theorem) [37] The point $(x^*, \lambda^*) \in \mathcal{X} \times \mathbb{R}_+^P$ is a primal-dual solution pair of problems (2) and (5) if and only if there holds:

$$
\mathcal{L}(x^*, \lambda) \leq \mathcal{L}(x^*, \lambda^*) \leq \mathcal{L}(x, \lambda^*) \forall x \in \mathcal{X}, \lambda \succeq 0. \tag{9}
$$

According to Theorem 1, if the PD subgradient method converges to a saddle point of the Lagrangian function (6), then it solves the original problem (2). Convergence properties of the PD method in (7) have been studied extensively; see, for example, [26], [27], [39]. In such methods, typically a subsequence of the sequence $(x^{(k)}, \lambda^{(k)})$ converges to a saddle point of the Lagrangian function in (6). To ensure the convergence of the whole sequence $(x^{(k)}, \lambda^{(k)})$, it is often assumed that the Lagrangian function is strictly convex in $x$ and strictly concave in $\lambda$, which does not hold in general however.

One of the approaches to circumventing this condition is the primal-dual perturbed (PDP) subgradient method in [21], [22]. Specifically, [21] suggests to update $x^{(k-1)}$ and $\lambda^{(k-1)}$ based on some perturbation points, denoted by $\alpha^{(k)}$ and $\beta^{(k)}$, respectively. The PDP updates are

$$
x^{(k)} = P_X(x^{(k-1)} - a_k \mathcal{L}_x(x^{(k-1)}, \beta^{(k)})), \tag{10a}
$$

$$
\lambda^{(k)} = (\lambda^{(k-1)} + a_k \mathcal{L}_\lambda(\alpha^{(k)}, \lambda^{(k-1)}))^+. \tag{10b}
$$

Note that, in (10a), we have replaced $\lambda^{(k-1)}$ by $\beta^{(k)}$, and, in (10b), replaced $x^{(k-1)}$ by $\alpha^{(k)}$, and thus $\mathcal{L}_x(x^{(k-1)}, \beta^{(k)})$ and $\mathcal{L}_\lambda(\alpha^{(k)}, \lambda^{(k-1)})$ are perturbed subgradients. It was shown in [21] that,
with carefully chosen \((\hat{\alpha}^{(k)}, \hat{\beta}^{(k)})\) and the step size \(\alpha_k\), the primal-dual iterates in (10) converge to a saddle point of (5), without any strict convexity and concavity assumptions on \(\mathcal{L}\).

There are several ways to generate the perturbation points \(\hat{\alpha}^{(k)}\) and \(\hat{\beta}^{(k)}\). Our interests lie specifically on those that are computationally as efficient as the PD subgradient updates in (10). Depending on the smoothness of \(\{g_{ip}\}_{p=1}^{P}\), we consider the following two methods:

**Gradient Perturbation Points:** A simple approach to computing the perturbation points is using the conventional gradient updates exactly as in (7), i.e.,

\[
\hat{\alpha}^{(k)} = \mathcal{P}_{\mathcal{X}}(x^{(k-1)} - \rho_1 \mathcal{L}_x(x^{(k-1)}, \lambda^{(k-1)})),
\]

\[
\hat{\beta}^{(k)} = (\lambda^{(k-1)} + \rho_2 \mathcal{L}_\lambda(x^{(k-1)}, \lambda^{(k-1)}))^+ \tag{11b}
\]

where \(\rho_1 > 0\) and \(\rho_2 > 0\) are constants. The PDP subgradient method thus combines (10) and (11), which involve two primal and dual subgradient updates. Even though the updates are relatively simple, this method requires smooth constraint functions \(g_{ip}\), \(p = 1, \ldots, P\).

In cases when \(g_{ip}\), \(p = 1, \ldots, P\), are non-smooth, we propose to use the following proximal perturbation points, which is novel and has not appeared in earlier works [21], [22].

**Proximal Perturbation Points:** When \(g_{ip}\), \(p = 1, \ldots, P\), are non-smooth, we compute the perturbation point \(\hat{\alpha}^{(k)}\) by the following proximal gradient update\(^3\) [40]:

\[
\hat{\alpha}^{(k)} = \arg \min_{\alpha \in \mathcal{X}} \left\{ \sum_{i=1}^{N} g_i^T(\alpha_i)\lambda^{(k-1)} + \frac{1}{2\rho_1} \left\| \alpha - (x^{(k-1)} - \rho_1 \nabla \mathcal{F}(x^{(k-1)})) \right\|^2 \right\} \tag{12}
\]

where \(\alpha = (\alpha_1^T, \ldots, \alpha_N^T)^T\) and

\[

\nabla \mathcal{F}(x^{(k-1)}) = \begin{bmatrix}
\nabla f_1^T(x_1^{(k-1)}) \nabla \mathcal{F}(\sum_{i=1}^{N} f_i(x_i^{(k-1)})) \\
\vdots \\
\nabla f_N^T(x_N^{(k-1)}) \nabla \mathcal{F}(\sum_{i=1}^{N} f_i(x_i^{(k-1)}))
\end{bmatrix}. \tag{13}
\]

It is worthwhile to note that, when \(g_{ip}\), \(p = 1, \ldots, P\), are some sparsity promoting functions (e.g., the 1-norm, 2-norm and the nuclear norm) that often arise in sparse regression problems [7], [41], [42], the proximal perturbation point in (12) can be solved very efficiently and may even have closed-form solutions. For example, if \(g_i(\alpha_i) = \|\alpha_i\|_1\) for all \(i\) \((P = 1)\), and \(\mathcal{X} = \mathbb{R}^{KN}\), (12) has a closed-form solution known as the soft thresholding operator [7]:

\[
\hat{\alpha}^{(k)} = (b - \lambda^{(k-1)} \rho_1 1)^+ + (-b - \lambda^{(k-1)} \rho_1 1)^+ , \tag{14}
\]

\(^3\)If not mentioned specifically, the norm function \(\| \cdot \|\) stands for the Euclidian norm.
where \( b = x^{(k-1)} - \rho_1 \nabla \bar{F}(x^{(k-1)}) \) and \( 1 \) is an all-one vector.

III. PROPOSED CONSSENSUS-BASED DISTRIBUTED PDP ALGORITHM

Our goal is to develop a distributed counterpart of the PDP subgradient method in (10). Let us recall Assumption 1 and consider the following saddle-point problem

\[
\max_{\lambda \in \mathcal{D}} \left\{ \min_{x_i \in \mathcal{X}_i, i = 1, \ldots, N} \mathcal{L}(x_1, \ldots, x_N, \lambda) \right\}
\]

(15)

where

\[
\mathcal{D} = \left\{ \lambda \succeq 0 \mid \|\lambda\| \leq D_\lambda \triangleq \frac{\bar{F}(\bar{x}) - \tilde{q}}{\gamma} + \delta \right\}
\]

(16)

in which \( \bar{x} = (\bar{x}_1^T, \ldots, \bar{x}_N^T)^T \) is a Slater point of (2), \( \tilde{q} = \min_{x_i \in \mathcal{X}_i, i = 1, \ldots, N} \mathcal{L}(x_1, \ldots, x_N, \tilde{\lambda}) \) is the dual function value for some arbitrary \( \tilde{\lambda} \succeq 0 \), \( \gamma = \min_{p = 1, \ldots, P} \left\{ -\sum_{i=1}^N g_{ip}(\bar{x}_i) \right\} \), and \( \delta > 0 \) is arbitrary. It has been shown in [43] that, under Assumption 1, the optimal dual solution of (5), denoted by \( \hat{\lambda}^\star \), satisfies

\[
\|\hat{\lambda}^\star\| \leq \frac{\bar{F}(\bar{x}) - \tilde{q}}{\gamma}
\]

(17)

and thus \( \hat{\lambda}^\star \) lies in \( \mathcal{D} \). Here we consider the saddle point problem (15), instead of the original Lagrange dual problem (5), because \( \mathcal{D} \) bounds the dual variable \( \lambda \) and thus also bounds the subgradient \( \mathcal{L}_x(x^{(k)}, \lambda^{(k)}) \) in (8a). This property is important in building the convergence of the distributed algorithm to be discussed shortly. Both (5) and (15) have the same optimal dual solution \( \hat{\lambda}^\star \) and attain the same optimal objective value. One can further verify that any saddle point of (5) is also a saddle point of (15). However, to prove the converse, some conditions are needed, as given in the following proposition.

**Proposition 1** (Primal-dual optimality conditions) [44] Suppose that Assumption 1 holds. Let \( (\hat{x}_1^\star, \ldots, \hat{x}_N^\star, \hat{\lambda}^\star) \) be a saddle point of (15). Then \( (\hat{x}_1^\star, \ldots, \hat{x}_N^\star) \) is an optimal solution for problem (2) if and only if

\[
\sum_{i=1}^N g_i(\hat{x}_i^\star) \preceq 0 \text{ and } (\hat{\lambda}^\star)^T \left( \sum_{i=1}^N g_i(\hat{x}_i^\star) \right) = 0.
\]

Proposition 1 implies that if a saddle point of (15) is primal feasible and satisfies the complementary slackness condition, then it is also a saddle point of problem (5), i.e., an optimal primal-dual solution pair of problem (2).
To have a distributed optimization algorithm for solving (15), in addition to $x_i^{(k)}$, we let each agent $i$ have a local copy of the dual iterate $\lambda_i^{(k)}$, denoted by $\tilde{\lambda}_i^{(k)}$. Moreover, each agent $i$ owns two auxiliary variables, denoted by $y_i^{(k)}$ and $z_i^{(k)}$, representing respectively the local estimates of the average values of the argument function $\frac{1}{N} \sum_{i=1}^{N} f_i(x_i^{(k)})$ and of the inequality constraint function $\frac{1}{N} \sum_{i=1}^{N} g_i(x_i^{(k)})$, for all $i=1,\ldots,N$. We consider a time-varying synchronous network model [11], where the network of agents at time $k$ is represented by a weighted directed graph $G(k) = (V, E(k), W(k))$. Here $(i,j) \in E(k)$ if and only if agent $i$ can receive messages from agent $j$, and $W(k) \in \mathbb{R}^{N \times N}$ is a weight matrix with each entry $[W(k)]_{ij}$ representing a weight that agent $i$ assigns to the incoming message on link $(i,j)$ at time $k$. If $(i,j) \in E(k)$, then $[W(k)]_{ij} > 0$ and $[W(k)]_{ij} = 0$ otherwise. The agents exchange messages with their neighbors (according to the network graph $G(k)$) in order to achieve consensus on $\lambda_i^{(k)}$, $\sum_{i=1}^{N} g_i(x_i^{(k)})$, and $\sum_{i=1}^{N} f_i(x_i^{(k)})$; while computing local perturbation points and primal-dual (sub-)gradient updates locally. Specifically, the proposed distributed consensus-based PDP method consists of the following steps at each iteration $k$:

1) Averaging consensus: For $i = 1,\ldots,N$, each agent $i$ sends $y_i^{(k-1)}$, $z_i^{(k-1)}$ and $\lambda_i^{(k-1)}$ to all its neighbors $j$ satisfying $(j,i) \in E(k)$; it also receives $y_j^{(k-1)}$, $z_j^{(k-1)}$ and $\lambda_j^{(k-1)}$ from its neighbors, and combines the received estimates, as follows:

$$\tilde{y}_i^{(k)} = \sum_{j=1}^{N} [W(k)]_{ij} y_j^{(k-1)}, \quad \tilde{z}_i^{(k)} = \sum_{j=1}^{N} [W(k)]_{ij} z_j^{(k-1)}, \quad \tilde{\lambda}_i^{(k)} = \sum_{j=1}^{N} [W(k)]_{ij} \lambda_j^{(k-1)}. \quad (18)$$

2) Perturbation point computation: For $i = 1,\ldots,N$, if functions $g_{ip}$, $p = 1,\ldots,P$, are smooth, then each agent $i$ computes the local perturbation points by

$$\alpha_i^{(k)} = P_{X_i} (x_i^{(k-1)} - \rho_1 [\nabla f_i^T (x_i^{(k-1)}) \nabla F(N \tilde{y}_i^{(k)}) + \nabla g_i^T (x_i^{(k-1)}) \tilde{\lambda}_i^{(k)}]) + \rho_1 [\nabla f_i^T (x_i^{(k-1)}) \nabla F(N \tilde{y}_i^{(k)}) + \nabla g_i^T (x_i^{(k-1)}) \tilde{\lambda}_i^{(k)}]) \quad (19a)$$

$$\beta_i^{(k)} = P_D (\tilde{\lambda}_i^{(k)} + \rho_2 N \tilde{z}_i^{(k)}). \quad (19b)$$

Note that, comparing to (11) and (12), agent $i$ here uses the most up-to-date estimates $N \tilde{y}_i^{(k)}$, $N \tilde{z}_i^{(k)}$ and $\tilde{\lambda}_i^{(k)}$ in place of $\sum_{i=1}^{N} f_i(x_i^{(k-1)})$, $\sum_{i=1}^{N} g_i(x_i^{(k-1)})$ and $\lambda^{(k-1)}$. If $g_{ip}$, $p = 1,\ldots,P$, are non-smooth, agent $i$ instead computes $\alpha_i^{(k)}$ by

$$\alpha_i^{(k)} = \arg \min_{\alpha_i \in X_i} \left\{ g_i^T (\alpha_i) \tilde{\lambda}_i^{(k)} + \frac{1}{2 \rho_1} \| \alpha_i - (x_i^{(k-1)} - \rho_1 [\nabla f_i^T (x_i^{(k-1)}) \nabla F(N \tilde{y}_i^{(k)})]) \|^2 \right\}, \quad (20)$$

for $i = 1,\ldots,N$. 

DRAFT September 9, 2013
Algorithm 1 Distributed Consensus-Based PDP Algorithm

1: Given initial variables $x_i^{(0)} \in X_i$, $\lambda_i^{(0)} \succeq 0$, $y_i^{(0)} = f_i(x_i^{(0)})$ and $z_i^{(0)} = g_i(x_i^{(0)})$ for each agent $i$, $i = 1, \ldots, N$; Set $k = 1$.

2: repeat

3: **Averaging consensus:** For $i = 1, \ldots, N$, each agent $i$ computes (18).

4: **Perturbation point computation:** For $i = 1, \ldots, N$, if $\{g_{ip}\}_{p=1}^P$ are smooth, then each agent $i$ computes the local perturbation points by (19); otherwise, each agent $i$ instead computes $\alpha_i^{(k)}$ by (20).

5: **Local variable updates:** For $i = 1, \ldots, N$, each agent $i$ updates (21), (22), (23) and (24) sequentially.

6: Set $k = k + 1$.

7: until a predefined stopping criterion (e.g., a maximum iteration number) is satisfied.

3) **Primal-dual perturbed subgradient update:** For $i = 1, \ldots, N$, each agent $i$ updates its primal and dual variables $(x_i^{(k)}, \lambda_i^{(k)})$ based on the local perturbation point $(\alpha_i^{(k)}, \beta_i^{(k)})$:

$$x_i^{(k)} = P_{X_i}(x_i^{(k-1)} - a_k[\nabla f_i^T(x_i^{(k-1)}) \nabla F(N \tilde{y}_i^{(k)}) + \nabla g_i^T(x_i^{(k-1)}) \beta_i^{(k)}])$$ \hspace{1cm} (21)

$$\lambda_i^{(k)} = P_{\Delta}(\lambda_i^{(k)} + a_k g_i(\alpha_i^{(k)})).$$ \hspace{1cm} (22)

4) **Auxiliary variable update:** For $i = 1, \ldots, N$, each agent $i$ updates variable $y_i^{(k)}$, $z_i^{(k)}$ with the changes of the local argument function $f_i(x_i^{(k)})$ and the constraint function $g_i(x_i^{(k)})$:

$$y_i^{(k)} = \tilde{y}_i^{(k)} + f_i(x_i^{(k)}) - f_i(x_i^{(k-1)}), \hspace{1cm} (23)$$

$$z_i^{(k)} = \tilde{z}_i^{(k)} + g_i(x_i^{(k)}) - g_i(x_i^{(k-1)}). \hspace{1cm} (24)$$

Algorithm 1 summarizes the above steps. We prove that Algorithm 1 converges under proper problem and network assumptions in the next section. Readers who are interested more in numerical performance of Algorithm 1 may go directly to Section V.

IV. Convergence Analysis

Next, in Section IV-A, we present additional assumptions on problem (2) and the network model. The main convergence results are presented in Section IV-B. The proofs are presented in Section IV-C and Section IV-D.
A. Assumptions

Assumption 2 (a) The sets \( X_i, i = 1, \ldots, N \), are convex and compact. In particular, for \( i = 1, \ldots, N \), there is a constant \( D_x > 0 \) such that
\[
\|x_i\| \leq D_x \quad \forall x_i \in X_i;
\] (25)

(b) The functions \( f_{i1}, \ldots, f_{iM}, i = 1, \ldots, N \), are continuously differentiable;

(c) The constraint functions \( g_{i1}, \ldots, g_{iP}, i = 1, \ldots, N \), are convex (not necessarily smooth).

Note that Assumption 2(a) and Assumption 2(b) imply that \( f_{i1}, \ldots, f_{iM} \) have uniformly bounded gradients (denoted by \( \nabla f_{im}, m = 1, \ldots, M \)) and are Lipschitz continuous, i.e., for some \( L_f > 0 \),
\[
\max_{1 \leq m \leq M} \|\nabla f_{im}(x_i)\| \leq L_f, \quad \forall x_i \in X_i
\] (26)
\[
\max_{1 \leq m \leq M} |f_{im}(x_i) - f_{im}(y_i)| \leq L_f \|x_i - y_i\| \quad \forall x_i, y_i \in X_i.
\] (27)

Similarly, Assumption 2(a) and Assumption 2(c) imply that \( g_{i1}, \ldots, g_{iP} \) have uniformly bounded subgradients (gradients if they are continuously differentiable) and are Lipschitz continuous, i.e., for some \( L_g > 0 \),
\[
\max_{1 \leq p \leq P} \|\nabla g_{ip}(x_i)\| \leq L_g \quad \forall x_i \in X_i,
\] (28)
\[
\max_{1 \leq p \leq P} |g_{ip}(x_i) - g_{ip}(y_i)| \leq L_g \|x_i - y_i\| \quad \forall x_i, y_i \in X_i.
\] (29)

In addition, each \( f_i \) and \( g_i \) are also bounded, i.e., there exist constants \( C_f > 0 \) and \( C_g > 0 \) such that for all \( i = 1, \ldots, N \),
\[
\|f_i(x_i)\| \leq C_f, \quad \|g_i(x_i)\| \leq C_g, \quad \forall x_i \in X_i,
\] (30)

where \( \|f_i(x_i)\| = \sqrt{\sum_{m=1}^{M} f_{im}^2(x_i)} \) and \( \|g_i(x_i)\| = \sqrt{\sum_{p=1}^{P} g_{ip}^2(x_i)} \).

We also need the following assumption on the network utility costs \( F \) and \( \bar{F} \):

Assumption 3 (a) The function \( F \) is continuously differentiable and has bounded and Lipschitz continuous gradients, i.e., for some \( G_F > 0 \) and \( L_F > 0 \), we have
\[
\|\nabla F(x) - \nabla F(y)\| \leq G_F \|x - y\| \quad \forall x, y \in \mathbb{R}^M,
\] (31)
\[
\|\nabla F(y)\| \leq L_F \quad \forall y \in \mathbb{R}^M;
\] (32)
(b) The function $\bar{F}$ is convex and has Lipschitz continuous gradients, i.e., for some $G_{\bar{F}} > 0$,

$$ \| \nabla \bar{F}(x) - \nabla \bar{F}(y) \| \leq G_{\bar{F}} \| x - y \| \quad \forall x, y \in \mathcal{X}. \quad (33) $$

Note that the convexity of $\bar{F}$ and Assumption 2(a) indicate that $\bar{F}$ is Lipschitz continuous, i.e., for some $L_{\bar{F}} > 0$,

$$ \| \bar{F}(x) - \bar{F}(y) \| \leq L_{\bar{F}} \| x - y \| \quad \forall x, y \in \mathcal{X}. \quad (34) $$

Assumptions 2 and 3 imply that problem (2) is a convex optimization problem. In cases that $g_{ip}$, $p = 1, \ldots, P$, are smooth, we make the following additional assumption:

**Assumption 4** The functions $g_{ip}$, $p = 1, \ldots, P$, are continuously differentiable and have Lipschitz continuous gradients, i.e., there exists a constant $G_g > 0$ such that

$$ \max_{1 \leq p \leq P} \| \nabla g_{ip}(x_i) - \nabla g_{ip}(y_i) \| \leq G_g \| x_i - y_i \| \quad \forall x_i, y_i \in \mathcal{X}_i. \quad (35) $$

We also have the following assumption on the network model [11], [17]:

**Assumption 5** The weighted graphs $G(k) = (\mathcal{V}, \mathcal{E}(k), W(k))$ satisfy:

(a) There exists a scalar $0 < \eta < 1$ such that $[W(k)]_{ii} > \eta$ for all $i, k$ and $[W(k)]_{ij} > \eta$ if $[W(k)]_{ij} > 0$.

(b) $W(k)$ is doubly stochastic: $\sum_{j=1}^{N} [W(k)]_{ij} = 1$ for all $i, k$ and $\sum_{i=1}^{N} [W(k)]_{ij} = 1 \forall j, k$.

(c) There is an integer $Q$ such that $(\mathcal{V}, \mathcal{E}(1), \ldots, \mathcal{E}(k+\ell))$ is strongly connected for all $k$.

Assumption 5 ensures that all the agents can sufficiently and equally influence each other in a long run.

**B. Main Convergence Results**

Let $A_k = \sum_{\ell=1}^{k} a_{\ell}$, and let

$$ x_i^{(k-1)} = \frac{1}{A_k} \sum_{\ell=1}^{k} a_{\ell} x_i^{(\ell-1)}, \quad i = 1, \ldots, N, \quad (36) $$

be the running weighted-averages of the primal iterates $x_i^{(0)}, \ldots, x_i^{(k-1)}$ generated by agent $i$ until time $k-1$. Our main convergence result for Algorithm 1 is given in the following theorem:
Theorem 2 Let Assumptions 1-5 hold, and let $\rho_1 \leq 1/(G_\bar{F} + D_\lambda \sqrt{PG_y})$. Assume that the step size sequence $\{a_k\}$ is non-increasing and such that $a_k > 0$ for all $k \geq 1$, $\sum_{k=1}^{\infty} a_k = \infty$ and $\sum_{k=1}^{\infty} a_k^2 < \infty$. Then, for $\hat{x}^{(k)} = (\hat{x}_1^{(k)}, \ldots, \hat{x}_N^{(k)})$ and $\lambda_i^{(k)}$, $i = 1, \ldots, N$, generated by Algorithm 1 using the gradient perturbation points in (19), we have

i) The sequence $\{\hat{x}^{(k)}\}$ converges to an optimal solution $x^* \in X$ of problem (2);

ii) The sequences $\{\lambda_i^{(k)}\}$, $i = 1, \ldots, N$, converge to a common dual optimal solution $\lambda^*$ of problem (2).

Theorem 2 indicates that the proposed distributed primal-dual algorithm asymptotically yields an optimal primal and dual solution pair for the original problem (2).

The same convergence result holds if the constraint functions $g_{ip}$, $p = 1, \ldots, P$, are non-smooth and the perturbation points $\alpha_i^{(k)}$ are computed following (20):

Theorem 3 Let Assumptions 1, 2, 3, and 5 hold, and let $\rho_1 \leq 1/G_\bar{F}$. Assume that the step size sequence $\{a_k\}$ is non-increasing and such that $a_k > 0$ for all $k \geq 1$, $\sum_{k=1}^{\infty} a_k = \infty$ and $\sum_{k=1}^{\infty} a_k^2 < \infty$. Let the sequences $\{\hat{x}^{(k)}\}$ and $\{\lambda_i^{(k)}\}$, $i = 1, \ldots, N$, be generated by Algorithm 1 using the perturbation points in (20) and (19b). Then, $\{\hat{x}^{(k)}\}$ and $\{\lambda_i^{(k)}\}$, $i = 1, \ldots, N$, converge to an optimal primal solution $x^* \in X$ and an optimal dual solution $\lambda^*$ of problem (2), respectively.

The proofs of Theorems 2 and 3 are presented in the next two subsections, respectively.

C. Proof of Theorem 2

In this subsection, we present the major steps for proving Theorem 2. Three key lemmas that will be used in the proof are presented first. The first is a deterministic version of the lemma in [45, Lemma 11, Chapter 2.2]:

Lemma 1 Let $\{b_k\}$, $\{d_k\}$ and $\{c_k\}$ be non-negative sequences. Suppose that $\sum_{k=1}^{\infty} c_k < \infty$ and $b_k \leq b_{k-1} - d_{k-1} + c_{k-1}$ $\forall k \geq 1$, then the sequence $\{b_k\}$ converges and $\sum_{k=1}^{\infty} d_k < \infty$.

Moreover, by extending the results in [17, Theorem 4.2] and [11, Lemma 8(a)], we establish the following result on the consensus of $\{\lambda_i^{(k)}\}$, $\{y_i^{(k)}\}$, and $\{z_i^{(k)}\}$ among agents.
Lemma 2 Suppose that Assumptions 1, 2 and 5 hold. If \( \{a_k\} \) is a positive, non-increasing sequence satisfying \( \sum_{k=1}^{\infty} a_k^2 < \infty \), then
\[
\sum_{k=1}^{\infty} a_k \| \lambda_i^{(k)} - \hat{\lambda}^{(k)} \| < \infty, \quad \lim_{k \to \infty} \| \lambda_i^{(k)} - \hat{\lambda}^{(k)} \| = 0, \quad \tag{37}
\]
\[
\sum_{k=1}^{\infty} a_k \| \hat{\lambda}_i^{(k)} - \hat{\lambda}^{(k-1)} \| < \infty, \quad \lim_{k \to \infty} \| \hat{\lambda}_i^{(k)} - \hat{\lambda}^{(k-1)} \| = 0, \quad \tag{38}
\]
\[
\sum_{k=1}^{\infty} a_k \| \hat{y}_i^{(k)} - \hat{y}^{(k-1)} \| < \infty, \quad \lim_{k \to \infty} \| \hat{y}_i^{(k)} - \hat{y}^{(k-1)} \| = 0, \quad \tag{39}
\]
\[
\sum_{k=1}^{\infty} a_k \| \hat{z}_i^{(k)} - \hat{z}^{(k-1)} \| < \infty, \quad \lim_{k \to \infty} \| \hat{z}_i^{(k)} - \hat{z}^{(k-1)} \| = 0, \quad \tag{40}
\]
for all \( i = 1, \ldots, N \), where
\[
\hat{y}^{(k)} = \frac{1}{N} \sum_{i=1}^{N} f_i(x_i^{(k)}), \quad \hat{z}^{(k)} = \frac{1}{N} \sum_{i=1}^{N} g_i(x_i^{(k)}), \quad \hat{\lambda}^{(k)} = \frac{1}{N} \sum_{i=1}^{N} \lambda_i^{(k)}. \quad \tag{41}
\]

The proof is omitted here due to limited space; interested readers may refer to the electronic companion [46]. Lemma 2 implies that the local variables \( \lambda_i^{(k)}, \hat{y}_i^{(k)} \) and \( \hat{z}_i^{(k)} \) at distributed agents will eventually achieve consensus on the values of \( \hat{\lambda}^{(k)}, \hat{y}^{(k)} \) and \( \hat{z}^{(k)} \), respectively.

The local perturbation points \( \hat{\alpha}_i^{(k)} \) and \( \hat{\beta}_i^{(k)} \) in (19) and (20) will also achieve consensus asymptotically. In particular, following (11), we define
\[
\hat{\alpha}_i^{(k)} = \mathcal{P}_{\chi_i}(x_i^{(k-1)} - \rho_1 [\nabla f_i^T(x_i^{(k-1)}) \nabla \mathcal{F}(N\hat{y}^{(k)}) + \nabla g_i^T(x_i^{(k-1)}) \hat{\lambda}^{(k-1)}]), \quad \tag{42a}
\]
\[
\hat{\beta}_i^{(k)} = \mathcal{P}_{\mathcal{D}}(\hat{\lambda}^{(k-1)} + \rho_2 N \hat{z}^{(k)}), \quad \tag{42b}
\]
for \( i = 1, \ldots, N \), as the ‘centralized’ counterparts of (19); similarly, following (12), we define
\[
\hat{\alpha}_i^{(k)} = \arg \min_{\alpha_i \in \chi_i} g_i^T(\alpha_i) \hat{\lambda}^{(k-1)} + \frac{1}{2\rho_1} \| \alpha_i - (x_i^{(k-1)} - \rho_1 \nabla f_i^T(x_i^{(k-1)}) \nabla \mathcal{F}(N\hat{y}^{(k-1)}) \|_2^2, \quad \tag{43}
\]
for \( i = 1, \ldots, N \), as the centralized counterparts of the proximal perturbation point in (20). We show in Appendix A the following lemma:

Lemma 3 Let Assumptions 2 and 3 hold. For \( \{\hat{\alpha}_i^{(k)}, \hat{\beta}_i^{(k)}\}_{i=1}^{N} \) in (19) and \( \{\hat{\alpha}_i^{(k)}, \ldots, \hat{\alpha}_N^{(k)}, \hat{\beta}^{(k)}\} \) in (42), it holds that
\[
\| \hat{\alpha}_i^{(k)} - \alpha_i^{(k)} \| \leq \rho_1 L_g \sqrt{P} \| \hat{\lambda}_i^{(k)} - \hat{\lambda}^{(k-1)} \| + \rho_1 G_{\mathcal{F}} L_f \sqrt{MN} \| \hat{y}_i^{(k)} - \hat{y}^{(k-1)} \|, \quad \tag{44}
\]
\[
\| \hat{\beta}_i^{(k)} - \beta_i^{(k)} \| \leq \| \hat{\lambda}_i^{(k)} - \hat{\lambda}^{(k-1)} \| + \rho_2 N \| \hat{z}_i^{(k)} - \hat{z}^{(k-1)} \|, \quad \tag{45}
\]
Lemma 4 Let Assumptions 2 and 3 hold. Then, for any \( x = (x_1^T, \ldots, x_N^T)^T \in \mathcal{X} \) and \( \lambda \in \mathcal{D} \), the following two inequalities are true:

\[
\|x^{(k)} - x\|^2 \leq \|x^{(k-1)} - x\|^2 - 2a_k \left( \mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(x, \hat{\beta}^{(k)}) \right) \\
+ a_k^2 N(\sqrt{ML_fL_F} + D_x \sqrt{PL_g})^2 + 2a_k ND_x \sqrt{ML_fG_F} \sum_{i=1}^N \|\hat{y}_i^{(k)} - \hat{y}^{(k-1)}\| \\
+ 2a_k D_x \sqrt{PL_g} \sum_{i=1}^N \|\hat{\lambda}_i^{(k)} - \hat{\lambda}^{(k-1)}\| + \rho_2 N \|\hat{z}_i^{(k)} - \hat{z}_i^{(k-1)}\|, \tag{46}
\]

\[
\sum_{i=1}^N \|\lambda_i^{(k)} - \lambda\|^2 \leq \sum_{i=1}^N \|\lambda_i^{(k-1)} - \lambda\|^2 + 2a_k \left( \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \lambda) \right) + a_k^2 N C_g^2 \\
+ 2a_k (2\rho_1 D_x \sqrt{LM} L_g + C_g) \|\hat{\lambda}_i^{(k)} - \hat{\lambda}^{(k-1)}\| + 4\rho_1 ND_x \sqrt{LM} L_g a_k \|\hat{y}_i^{(k)} - \hat{y}_i^{(k-1)}\|. \tag{47}
\]

The proof is given in Appendix B. The second ingredient is to exploit the relation between the primal-dual iterates \( (x^{(k-1)}, \hat{\lambda}^{(k-1)}) \) and the perturbation points \( (\hat{\alpha}^{(k)}, \hat{\beta}^{(k)}) \), which provides the key property for \( (\hat{x}_1^{(k)}, \ldots, \hat{x}_N^{(k)}, \hat{\lambda}^{(k)}) \) converging to a saddle point of (15).

Lemma 5 Let Assumptions 2, 3 and 4 hold. For the gradient perturbation points \( (\hat{\alpha}^{(k)}, \hat{\beta}^{(k)}) \) in (42), it holds true that

\[
\mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \\
\geq \left( \frac{1}{\rho_1} - (G_F + D_x \sqrt{PG_g}) \right) \|x^{(k-1)} - \hat{\alpha}^{(k)}\|^2 + \frac{1}{\rho_2} \|\hat{\lambda}^{(k-1)} - \hat{\beta}^{(k)}\|^2. \tag{48}
\]
Moreover, let $\rho_1 \leq 1/(G_\tilde{F} + D_\lambda \sqrt{P}G_g)$, and suppose that $\mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \to 0$ and $(x^{(k-1)}, \lambda^{(k-1)})$ converges to some limit point $(\hat{x}^*, \hat{\lambda}^*) \in \mathcal{X} \times \mathcal{D}$ as $k \to \infty$. Then $(\hat{x}^*, \hat{\lambda}^*)$ is a saddle point of (15).

The proof is presented in Appendix C. By the preceding lemmas, we are able to show the first fact as stated in the following lemma.

**Lemma 6** Let Assumptions 2-5 hold, and let $\rho_1 \leq 1/(G_\tilde{F} + D_\lambda \sqrt{P}G_g)$. Assume that the step size $a_k > 0$ is a non-increasing sequence satisfying $\sum_{k=1}^{\infty} a_k = \infty$ and $\sum_{k=1}^{\infty} a_k^2 < \infty$. Then

$$
\lim_{k \to \infty} \|x_i^{(k)} - \hat{x}_i^*\| = 0, \quad i = 1, \ldots, N,
\lim_{k \to \infty} \|\lambda^{(k)} - \hat{\lambda}^*\| = 0,
$$

where $\hat{x}^* = (\hat{x}_1^*, \ldots, \hat{x}_N^*)^T \in \mathcal{X}$ and $\hat{\lambda}^* \in \mathcal{D}$ form a saddle point of problem (15).

**Proof of Lemma 6:** By the compactness of the set $\mathcal{X}$ and the continuity of the functions $\tilde{F}$ and $g$, problem (2) has a solution. By Assumption 1, the dual problem also has a solution. By construction of the set $\mathcal{D}$ in (16), all dual optimal solutions are contained in the set $\mathcal{D}$. We let $x^* = ((x_1^*)^T, \ldots, (x_N^*)^T)^T \in \mathcal{X}$ and $\lambda^* \in \mathcal{D}$ be an arbitrary saddle point of (15), and we apply Lemma 4 with $x = (x_1^T, \ldots, x_N^T)^T = x^*$ and $\lambda = \lambda^*$. By summing (46) and (47), we obtain the following inequality

$$
(\|x^{(k)} - x^*\|^2 + \sum_{i=1}^{N} \|\lambda_i^{(k)} - \lambda^*\|^2) \leq (\|x^{(k-1)} - x^*\|^2 + \sum_{i=1}^{N} \|\lambda_i^{(k-1)} - \lambda^*\|^2)
+ \tilde{\gamma}_k - 2a_k \left(\mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(x^*, \beta^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) + \mathcal{L}(\hat{\alpha}^{(k)}, \lambda^*)\right),
$$

where

$$
\tilde{\gamma}_k \triangleq a_k^2 N [(\sqrt{M}L_f L_x + D_\lambda \sqrt{P}L_g)^2 + C_g^2]
+ 2[D_x \sqrt{P}L_g + C_g + 2 \rho_1 PD_\lambda L_g^2] \sum_{i=1}^{N} (a_k \|\hat{\lambda}_i^{(k)} - \lambda^{(k-1)}\|) + 2N \sqrt{M}L_f G_F (D_x)
+ 2\rho_1 D_\lambda \sqrt{P}L_g \sum_{i=1}^{N} (a_k \|\hat{y}_i^{(k)} - \hat{y}^{(k-1)}\|) + 2N \rho_2 D_x \sqrt{P}L_g \sum_{i=1}^{N} (a_k \|\hat{z}_i^{(k)} - \hat{z}^{(k-1)}\|).
$$

First of all, by Theorem 1, we have

$$
\mathcal{L}(\hat{\alpha}^{(k)}, \lambda^*) - \mathcal{L}(x^*, \lambda^*) \geq 0, \quad \mathcal{L}(x^*, \lambda^*) - \mathcal{L}(x^*, \hat{\beta}^{(k)}) \geq 0,
$$

September 9, 2013
implying that \( \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^*) - \mathcal{L}(\alpha^*, \beta^{(k)}) \geq 0 \). Hence we deduce from (52) that

\[
(\|x^{(k)} - x^*\|^2 + \sum_{i=1}^{N} \|\lambda_i^{(k)} - \lambda^*\|^2) \leq (\|x^{(k-1)} - x^*\|^2 + \sum_{i=1}^{N} \|\lambda_i^{(k-1)} - \lambda^*\|^2) + \tilde{c}_k - 2\alpha_k(\mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)})).
\]

(53)

Secondly, by \( \sum_{k=1}^{\infty} a_k^2 < \infty \) and by Lemma 2, we see that all the four terms in \( \tilde{c}_k \) are summable over \( k \), and thus \( \sum_{k=1}^{\infty} \tilde{c}_k < \infty \). Thirdly, by Lemma 5 and under the premise of \( \rho_1 \leq 1/(G\bar{x} + D\lambda \sqrt{F}G_g) \), we have \( \mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \geq 0 \). Therefore, by applying Lemma 1 to relation (53), we conclude that the sequence \{\( \|x^{(k)} - x^*\|^2 + \sum_{i=1}^{N} \|\lambda_i^{(k)} - \lambda^*\|^2 \)\} converges for any saddle point \((x^*, \lambda^*)\), and it holds that \( \sum_{k=1}^{\infty} a_k \left( \mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \right) < \infty \).

Because \( \sum_{k=1}^{\infty} a_k = \infty \), the preceding relation implies that

\[
\liminf_{k \to \infty} \mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) = 0.
\]

(54)

Equation (54) implies that there exists a subsequence \( \ell_1, \ell_2, \ldots \) such that

\[
\mathcal{L}(x^{(\ell_k-1)}, \hat{\beta}^{(\ell_k)}) - \mathcal{L}(\hat{\alpha}^{(\ell_k)}, \hat{\lambda}^{(\ell_k-1)}) \to 0 \text{ as } k \to \infty.
\]

(55)

According to Lemma 5, the above equation indicates that

\[
\lim_{k \to \infty} \|x^{(\ell_k-1)} - \hat{\alpha}^{(\ell_k)}\| = 0, \quad \lim_{k \to \infty} \|\hat{\lambda}^{(\ell_k-1)} - \hat{\beta}^{(\ell_k)}\| = 0.
\]

(56)

Moreover, because \{\( (x^{(\ell_k-1)}, \hat{\lambda}^{(\ell_k-1)}) \)\} \( \subset \mathcal{X} \times \mathcal{D} \) is a bounded sequence, there must exist a limit point, say \( (\hat{x}^*, \hat{\lambda}^*) \in \mathcal{X} \times \mathcal{D} \), such that

\[
x^{(\ell_k-1)} \to \hat{x}^*, \quad \hat{\lambda}^{(\ell_k-1)} \to \hat{\lambda}^*, \text{ as } k \to \infty.
\]

(57)

Under the premise of \( \rho_1 \leq 1/(G\bar{x} + D\lambda \sqrt{F}G_g) \), and by (55) and (57), we obtain from Lemma 5 that \( (\hat{x}^*, \hat{\lambda}^*) \in \mathcal{X} \times \mathcal{D} \) is a saddle point of (15). Moreover, because

\[
\|x^{(\ell_k)} - \hat{x}^*\|^2 + \sum_{i=1}^{N} \|\lambda_i^{(\ell_k)} - \hat{\lambda}^*\|^2 \leq \|x^{(\ell_k)} - \hat{x}^*\|^2 + \sum_{i=1}^{N} (\|\lambda_i^{(\ell_k)} - \hat{\lambda}^{(\ell_k)}\|^2 + \|\hat{\lambda}^{(\ell_k)} - \hat{\lambda}^*\|)^2,
\]

we obtain from Lemma 2 and (57) that the sequence \{\( \|x^{(k)} - \hat{x}^*\|^2 + \sum_{i=1}^{N} \|\lambda_i^{(k)} - \hat{\lambda}^*\|^2 \)\} has a limit value equal to zero. Since the sequence \{\( \|x^{(k)} - \hat{x}^*\|^2 + \sum_{i=1}^{N} \|\lambda_i^{(k)} - \hat{\lambda}^*\|^2 \)\} converges for any saddle point of (15), we conclude that \{\( \|x^{(k)} - \hat{x}^*\|^2 + \sum_{i=1}^{N} \|\lambda_i^{(k)} - \hat{\lambda}^*\|^2 \)\} in fact converges to zero, and therefore (49) is proved. Finally, relation (50) can also be obtained by (49), (53) and (48), provided that \( \rho_1 \leq 1/(G\bar{x} + D\lambda \sqrt{F}G_g) \).
According to [44, Lemma 3], if \( x^{(k)} \to x^* \) as \( k \to \infty \), then its weighted running average \( x^{(k)} \) defined in (36) also converges to \( x^* \) as \( k \to \infty \). What remains is to show the second fact that \( (\hat{x}^{(k)}, \hat{\lambda}^{(k)}) \) asymptotically satisfies the optimality conditions given by Proposition 1. We prove in Appendix D that the following lemma holds.

**Lemma 7** Under the assumptions of Lemma 6, it holds

\[
\lim_{k \to \infty} \left\| \left( \sum_{i=1}^{N} g_i(x_i^{(k)}) \right)^+ \right\| = 0, \quad \lim_{k \to \infty} (\hat{\lambda}^{(k)})^T \left( \sum_{i=1}^{N} g_i(\hat{x}_i^{(k)}) \right) = 0. \tag{58}
\]

By Lemma 6, Lemma 7 and Proposition 1, we conclude that Theorem 2 is true. Finally, we remark that when the step size \( a_k \) has the form of \( a/(b+k) \) where \( a > 0, b \geq 0 \), one can simply consider the running average below [44]

\[
\bar{x}^{(k)} = \frac{1}{k} \sum_{\ell=0}^{k-1} x^{(\ell)} = \left( 1 - \frac{1}{k} \right) x^{(k-1)} + \frac{1}{k} x^{(k-1)}, \tag{59}
\]

instead of the running weighted-average in (36) while Lemma 7 still holds true.

**D. Proof of Theorem 3**

Theorem 3 essentially can be obtained in the same line as the proof of Theorem 2, except for Lemma 5. What we need to show here is that the centralized proximal perturbation point \( \hat{\alpha}^{(k)} \) in (43) and \( \hat{\beta}^{(k)} \) in (42b) and the primal-dual iterates \( (x^{(k-1)}, \lambda^{(k-1)}) \) satisfy a result similar to Lemma 5. The lemma below is proved in Appendix E:

**Lemma 8** Let Assumptions 2 and 3 hold. For the centralized perturbation points \( \hat{\alpha}^{(k)} \) in (43) and \( \hat{\beta}^{(k)} \) in (42b), it holds true that

\[
\mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \geq \left( \frac{1}{2\rho_1} - \frac{G_F}{2} \right) \| x^{(k-1)} - \hat{\alpha}^{(k)} \|^2 + \frac{1}{\rho_2} \| \hat{\lambda}^{(k-1)} - \hat{\beta}^{(k)} \|^2. \tag{60}
\]

Moreover, let \( \rho_1 \leq 1/G_F \), and suppose that \( \mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \to 0 \) and \( (x^{(k-1)}, \lambda^{(k-1)}) \) converges to some limit point \( (\hat{x}^*, \hat{\lambda}^*) \in \mathcal{X} \times \mathcal{D} \) as \( k \to \infty \). Then \( (\hat{x}^*, \hat{\lambda}^*) \) is a saddle point of (15).

Analogous to Lemma 6, as long as \( \rho_1 \leq \frac{1}{G_F} \), the primal-dual iterates \( (x^{(k)}, \hat{\lambda}^{(k)}) \) converge to a saddle point of (15).
V. SIMULATION RESULTS

In this section, we examine the efficacy of the proposed distributed PDP method (Algorithm 1) by considering the DSM problem discussed in Section II-B. We consider the DSM problem presented in (3) and (4). The cost functions were set to $C_p(\cdot) = \pi_p \| \cdot \|^2$ and $C_s(\cdot) = \pi_s \| \cdot \|^2$, respectively, where $\pi_p$ and $\pi_s$ are some price parameters. The load profile function $\psi_i(x_i)$ is based on the load model in [18], which were proposed to model deferrable, non-interruptible loads such as electrical vehicle, washing machine and tumble dryer et. al. According to [18], $\psi_i(x_i)$ can be modeled as a linear function, i.e., $\psi_i(x_i) = \Psi_i x_i$, where $\Psi_i \in \mathbb{R}^{T \times T}$ is a coefficient matrix composed of load profiles of appliances of customer $i$. The control variable $x_i \in \mathbb{R}^T$ determines the operation scheduling of appliances of customer $i$. Due to some physical conditions and quality of service constraints, each $x_i$ is subject to a local constraint set $X_i = \{ x_i \in \mathbb{R}^T \mid A_i d_i \preceq b_i, \ l_i \leq d_i \leq u_i \}$ where $A_i \in \mathbb{R}^{T \times T}$ and $l_i, u_i \in \mathbb{R}^T$ [18]. The problem formulation corresponding to (3) is thus given by

$$\min_{x_i \in X_i, i = 1, \ldots, N} \pi_p \left\| \left( \sum_{i=1}^{N} \Psi_i x_i - p \right) \right\|^2 + \pi_s \left\| \left( p - \sum_{i=1}^{N} \Psi_i x_i \right) \right\|^2. \tag{61}$$

Analogous to (4), problem (61) can be reformulated as

$$\min_{x_i \in X_i, i = 1, \ldots, N, \ z \geq 0} \pi_p \left\| z \right\|^2 + \pi_s \left\| z - \sum_{i=1}^{N} \Psi_i x_i + p \right\|^2 \tag{62a}$$

$$\text{s.t. } \sum_{i=1}^{N} \Psi_i x_i - p - z \preceq 0, \tag{62b}$$

to which the proposed distributed PDP method can be applied. We consider a scenario with 400 customers ($N = 400$), and follow the same methods as in [47] to generate the power bidding $p$ and coefficients $\Psi_i, A_i, b_i, l_i, u_i, i = 1, \ldots, N$. The network graph $G$ was randomly generated. The price parameters $\pi_p$ and $\pi_s$ were simply set to $1/N$ and $0.8/N$, respectively. In addition to the distributed PD method in [15], we also compare the proposed distributed PDP method with the distributed dual subgradient (DDS) method$^4$ [18], [25]. This method is based

$^4$One can utilize the linear structure to show that (61) is equivalent to the following saddle point problem (by Lagrange dual)

$$\max_{\lambda, \eta \geq 0} \left\{ \min_{x_i \in X_i, i = 1, \ldots, N} - \frac{1}{4\pi_p} ||\lambda||^2 - \frac{1}{4\pi_s} ||\eta||^2 + (\lambda - \eta)^T \left( \sum_{i=1}^{N} \Psi_i x_i - p \right) \right\} \tag{63}$$

to which the method in [15] and the DDS method [25] can be applied.
on the same idea as the dual decomposition technique [25], where, given the dual variables, each customer globally solves the corresponding inner minimization problem. The average consensus subgradient technique [10] is applied to the dual domain for distributed dual optimization.

Figure 1(a) shows the convergence curves of the three methods under test. The curves shown in this figure are the corresponding objective values in (61) of the running average iterates of the three methods. The step size of the distributed PD method in [15] was set to $a_k = \frac{15}{10^k}$ and that of the DDS method was set to $a_k = \frac{0.05}{10^k}$. For the proposed distributed PDP method, $a_k$, $\rho_1$ and $\rho_2$ were respectively set to $a_k = \frac{0.1}{10^k}$ and $\rho_1 = \rho_2 = 0.001$. From this figure, we observe that the proposed distributed PDP method and the DDS method exhibit comparable convergence behavior; both methods converge within 100 iterations and outperform the distributed PD method in [15]. One should note that the DDS method is computational more expensive than the proposed distributed PDP method since, in each iteration, the former requires to globally solve the inner minimization problem while the latter takes twice primal subgradient updates only\(^5\).

In Figure 1(b), we display the load profiles of the power supply and the unscheduled load (without DSM), while, in Figure 1(c), we show the load profiles scheduled by the three optimization methods under consideration. The results were obtained by respectively combining each of the optimization method with the certainty equivalent control (CEC) approach in [18, Algorithm 1] to handle a stochastic counterpart of problem (61). The stopping criterion was set to the maximum iteration number of 500. We can observe from this figure that, for all the three methods, the power balancing can be much improved compared to that without DSM control. However, we still can observe from Figure 1(c) that the proposed PDP method and the DDS method exhibit better results than the distributed PD method in [15]. Specifically, the cost in (61) is $4.49 \times 10^4$ KW for the unscheduled load whereas that of the load scheduled by the proposed distributed PDP method is $2.44 \times 10^4$ KW (45.65\% reduction). The cost for the load scheduled by the distributed DDS method is slightly lower which is $2.38 \times 10^4$ KW; whereas that scheduled by the distributed PD method in [15] has a higher cost of $3.81 \times 10^4$ KW.

As discussed in Section II-B, problem (2) also incorporates the important regression problems.

\(^5\)For the proposed PDP method in Algorithm 1, the complexity order per iteration per customer is given by $O(4T)$ [see (19), (21) and (22)]. For the DDS method, each customer has to solve the inner linear programming (LP) in (63) $\min_{x_i \in X_i}(\lambda - \eta)^T \Psi_i x_i$ per iteration. According to [48], the worst-case complexity of interior point methods for solving an LP is given by $O(T^{0.5}(3T^2 + T^3)) \approx O(T^{3.5})$. 

September 9, 2013 DRAFT
Fig. 1: Numerical results for the smart grid DSM problem (61) with 400 customers.

In [36], we have applied the proposed PDP method to solving a distributed sparse regression problem (which has a non-smooth constraint function). The associated simulation results can be found in [36].

VI. CONCLUSIONS AND FUTURE WORKS

In this paper, we have presented a distributed consensus-based PDP algorithm for solving the problem formulated in (2), which has a globally coupled cost function and inequality constraints. The algorithm employs the average consensus technique and the primal-dual perturbed (sub-
We have provided a convergence analysis showing that the proposed algorithm enables the agents across the network to achieve a global optimal primal-dual solution of the considered problem in a distributed manner. Moreover, the effectiveness of the proposed algorithm has been demonstrated by applying it to a sparse linear regression problem and a smart grid demand response control problem. In particular, the proposed algorithm is shown to have better convergence property than the distributed PD method in [15] which does not have perturbation. In addition, the proposed algorithm performs comparably with the distributed dual subgradient method [25] for the demand response control problem, even though the former is computationally cheaper.

There are several interesting research directions to pursue in the future. One direction is to extend the algorithm to asynchronous network models such as those considered in [49], [50]. The other direction is to study the convergence rate of the proposed PDP algorithm. In addition, the current practiced stopping criterion is a maximum iteration number. It would be interesting to study advanced distributed stopping criterion (e.g., based on the primal-dual optimality conditions) so that the algorithm can stop wisely in a distributed manner.

Appendix A

Proof of Lemma 3

We first show (45). By definitions in (42b) and (19b), and by the non-expansiveness of projection, we readily obtain

$$
\|\hat{\beta}^{(k)} - \beta_i^{(k)}\| \leq \left\| \mathcal{P}_D \left( \hat{\lambda}_i^{(k)} + \rho_2 \tilde{N} \tilde{z}_i^{(k)} \right) - \mathcal{P}_D \left( \hat{\lambda}_i^{(k-1)} + \rho_2 \tilde{N} \tilde{z}_i^{(k-1)} \right) \right\|
$$

$$
\leq \|\hat{\lambda}_i^{(k)} - \hat{\lambda}_i^{(k-1)}\| + \rho_2 \tilde{N} \|\tilde{z}_i^{(k)} - \tilde{z}_i^{(k-1)}\|.
$$

Equation (44) for the $\alpha_i^{(k)}$ in (19a) and $\hat{\alpha}_i^{(k)}$ in (42a) can be shown in a similar line:

$$
\|\alpha_i^{(k)} - \hat{\alpha}_i^{(k)}\| = \left\| \mathcal{P}_{\chi_i} \left( x_i^{(k-1)} - \rho_1 \left[ \nabla f_i^T(x_i^{(k-1)}) \nabla \mathcal{F}(N\tilde{y}_i^{(k)}) + \nabla g_i^T(x_i^{(k-1)}) \hat{\lambda}_i^{(k)} \right] \right) - \mathcal{P}_{\chi_i} \left( x_i^{(k-1)} - \rho_1 \left[ \nabla f_i^T(x_i^{(k-1)}) \nabla \mathcal{F}(N\tilde{y}_i^{(k-1)}) + \nabla g_i^T(x_i^{(k-1)}) \hat{\lambda}_i^{(k-1)} \right] \right) \right\|
$$

$$
\leq \rho_1 \|\nabla f_i^T(x_i^{(k-1)})\| \|\nabla \mathcal{F}(N\tilde{y}_i^{(k)}) - \nabla \mathcal{F}(N\tilde{y}_i^{(k-1)})\| + \rho_1 \|\nabla g_i(x_i^{(k-1)})\| \|\hat{\lambda}_i^{(k)} - \hat{\lambda}_i^{(k-1)}\|
$$

$$
\leq \rho_1 G_f \sqrt{F} \|\hat{\lambda}_i^{(k)} - \hat{\lambda}_i^{(k-1)}\| + \rho_1 G_f L_f \sqrt{MN} \|\tilde{y}_i^{(k)} - \tilde{y}_i^{(k-1)}\|,
$$

(A.1)
where, in the second inequality, we have used the boundedness of gradients (cf. (26), (28)) and the Lipchitz continuity of $\nabla F$ (Assumption 3).

To show that (44) holds for $\alpha_i^{(k)}$ in (20) and $\hat{\alpha}_i^{(k)}$ in (43), we use the following lemma:

**Lemma 9** [51, Lemma 4.1] If $y^* = \arg \min_{y \in \mathcal{Y}} J_1(y) + J_2(y)$, where $J_1 : \mathbb{R}^n \to \mathbb{R}$ and $J_2 : \mathbb{R}^n \to \mathbb{R}$ are convex functions and $\mathcal{Y}$ is a closed convex set. Moreover, $J_2$ is continuously differentiable. Then $y^* = \arg \min_{y \in \mathcal{Y}} \{ J_1(y) + \nabla J_2^T(y^*) \cdot y \}$.

By applying the above lemma to (20) using $J_1(\alpha_1) = g_i^T(\alpha_1) \hat{\lambda}_i^{(k)}$ and

$$J_2(\alpha_i) = \frac{1}{2\rho_1} \| \alpha_i - (x_i^{(k-1)} - \rho_1 \nabla f_i^T(x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k)})) \|^2,$$

we obtain

$$\alpha_i^{(k)} = \arg \min_{\alpha_i \in \mathcal{X}_i} g_i^T(\alpha_i) \hat{\lambda}_i^{(k)} + (\nabla f_i^T(x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k)})) + \frac{1}{\rho_1} (\alpha_i^{(k)} - x_i^{(k-1)})^T \alpha_i. \quad (A.2)$$

Similarly, applying Lemma 9 to (43), we obtain

$$\hat{\alpha}_i^{(k)} = \arg \min_{\alpha_i \in \mathcal{X}_i} g_i^T(\alpha_i) \hat{\lambda}_i^{(k-1)} + (\nabla f_i^T(x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k-1)})) + \frac{1}{\rho_1} (\hat{\alpha}_i^{(k)} - x_i^{(k-1)})^T \alpha_i. \quad (A.3)$$

From (A.2) it follows that

$$g_i^T(\alpha_i^{(k)}) \hat{\lambda}_i^{(k)} + (\nabla f_i^T(x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k)})) + \frac{1}{\rho_1} (\alpha_i^{(k)} - x_i^{(k-1)})^T \alpha_i^{(k)}$$

$$\leq g_i^T(\hat{\alpha}_i^{(k)}) \hat{\lambda}_i^{(k)} + (\nabla f_i^T(x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k-1)})) + \frac{1}{\rho_1} (\hat{\alpha}_i^{(k)} - x_i^{(k-1)})^T \hat{\alpha}_i^{(k)},$$

which is equivalent to

$$0 \leq (g_i^T(\alpha_i^{(k)}) - g_i^T(\hat{\alpha}_i^{(k)})) \hat{\lambda}_i^{(k)}$$

$$+ \nabla f_i^T(x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k-1)})(\alpha_i^{(k)} - \hat{\alpha}_i^{(k)}) + \frac{1}{\rho_1}(\alpha_i^{(k)} - x_i^{(k-1)})(\alpha_i^{(k)} - \hat{\alpha}_i^{(k)}). \quad (A.4)$$

Similarly, equation (A.3) implies that

$$0 \leq (g_i^T(\alpha_i^{(k)}) - g_i^T(\hat{\alpha}_i^{(k)})) \hat{\lambda}_i^{(k-1)}$$

$$+ \nabla f_i^T(x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k-1)})(\alpha_i^{(k)} - \hat{\alpha}_i^{(k)}) + \frac{1}{\rho_1}(\alpha_i^{(k)} - x_i^{(k-1)})(\alpha_i^{(k)} - \hat{\alpha}_i^{(k)}). \quad (A.5)$$

By combining (A.4) and (A.5), we obtain

$$\frac{1}{\rho_1} \| \alpha_i^{(k)} - \hat{\alpha}_i^{(k)} \|^2 \leq (g_i^T(\alpha_i^{(k)}) - g_i^T(\hat{\alpha}_i^{(k)})) \hat{\lambda}_i^{(k)} - \hat{\lambda}_i^{(k-1)}$$

$$+ \nabla f_i^T(x_i^{(k-1)})(\nabla F(N \hat{y}_i^{(k)}) - \nabla F(N \hat{y}_i^{(k-1)}))(\alpha_i^{(k)} - \hat{\alpha}_i^{(k)})$$

$$\leq \left( \sqrt{P}L_y \| \hat{\lambda}_i^{(k)} - \hat{\lambda}_i^{(k-1)} \| + G \sqrt{M} \| \hat{y}_i^{(k)} - \hat{y}_i^{(k-1)} \| \right) \| \alpha_i^{(k)} - \hat{\alpha}_i^{(k)} \|,$$
where we have used the boundedness of gradients (cf. (26), (28)), the Lipschitz continuity of \( \nabla F \) (Assumption 3) as well as the Lipschitz continuity of \( g_i \) (in (29)). The desired result in (44) follows from the preceding relation.

\[ \square \]

\section*{Appendix B}

\textbf{Proof of Lemma 4:}

By (21), the non-expansiveness of projection [38], the subgradient boundedness in (26), (28) and (32), and by (16), one can show that, for any \( x = (x_1, \ldots, x_N) \in \mathcal{X}, \)

\[
\sum_{i=1}^{N} \| x_i^{(k)} - x_i \|^2 = \sum_{i=1}^{N} \| P_{\mathcal{X}_i} \left( x_i^{(k-1)} - a_k \left[ \nabla f_i^T (x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k)}) + \nabla g_i^T (x_i^{(k-1)}) \beta_i^{(k)} \right] \right) - x_i \|^2 \\
\leq \sum_{i=1}^{N} \| x_i^{(k-1)} - x_i \|^2 + a_k^2 N (\sqrt{M} L_f L_F + D_x \sqrt{P} L_g)^2 \\
-2a_k \sum_{i=1}^{N} (x_i^{(k-1)} - x_i)^T (\nabla f_i^T (x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k)}) + \nabla g_i^T (x_i^{(k-1)}) \beta_i^{(k)}). \tag{A.6}
\]

The last term in (A.6) can be further bounded as follows:

\[
-2a_k \sum_{i=1}^{N} (x_i^{(k-1)} - x_i)^T (\nabla f_i^T (x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k)}) + \nabla g_i^T (x_i^{(k-1)}) \beta_i^{(k)}) \\
= -2a_k \sum_{i=1}^{N} (x_i^{(k-1)} - x_i)^T (\nabla f_i^T (x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k)}) + \nabla g_i^T (x_i^{(k-1)}) \dot{\beta}^{(k)}) \\
- 2a_k \sum_{i=1}^{N} (x_i^{(k-1)} - x_i)^T \nabla f_i^T (x_i^{(k-1)}) (\nabla F(N \hat{y}_i^{(k)}) - \nabla F(N \hat{y}_i^{(k-1)})) \\
- 2a_k \sum_{i=1}^{N} (x_i^{(k-1)} - x_i)^T \nabla g_i^T (x_i^{(k-1)}) (\beta_i^{(k)} - \dot{\beta}^{(k)}) \\
\leq -2a_k \sum_{i=1}^{N} (x_i^{(k-1)} - x_i)^T (\nabla f_i^T (x_i^{(k-1)}) \nabla F(N \hat{y}_i^{(k)}) + \nabla g_i^T (x_i^{(k-1)}) \dot{\beta}^{(k)}) \\
+ 2a_k N D_x \sqrt{M} L_f G_F \sum_{i=1}^{N} \| \hat{y}_i^{(k)} - \hat{y}^{(k-1)} \| + 2a_k D_x \sqrt{P} L_g \sum_{i=1}^{N} \| \beta_i^{(k)} - \dot{\beta}^{(k)} \| \\
\leq -2a_k (\mathcal{L}(x^{(k-1)}, \dot{\beta}^{(k)}) - \mathcal{L}(x, \dot{\beta}^{(k)})) \\
+ 2a_k N D_x \sqrt{M} L_f G_F \sum_{i=1}^{N} \| \hat{y}_i^{(k)} - \hat{y}^{(k-1)} \| + 2a_k D_x \sqrt{P} L_g \sum_{i=1}^{N} \| \beta_i^{(k)} - \dot{\beta}^{(k)} \|, \tag{A.7}
\]
where the first inequality is obtained by the subgradient boundedness, the Lipschitz continuity of $\nabla F$, and the compactness of $X_i$ and $D$ (cf. (25), (31), (26), (28)), and the second inequality is due to the definition of the subgradient of a convex function, i.e., $L(x^{(k-1)}, \hat{\beta}^{(k)}) + (x - x^{(k-1)})^T L_x(x^{(k-1)}, \hat{\beta}^{(k)}) \leq L(x, \hat{\beta}^{(k)}) \quad \forall x \in X$. By combining (A.6) and (A.7) and applying (45) in Lemma 3, we obtain (46).

By using (22) and a line of analysis similar to that of the proof of (46), we can obtain, for any $\lambda \in D$,

$$\sum_{i=1}^{N} \|\lambda_i^{(k)} - \lambda\|^2 \leq \sum_{i=1}^{N} \|\hat{\lambda}_i^{(k)} - \lambda\|^2 + a_k^2 \sum_{i=1}^{N} \|g_i(\alpha_i^{(k)})\|^2 + 2a_k \sum_{i=1}^{N} (\hat{\lambda}_i^{(k)} - \lambda)^T g_i(\alpha_i^{(k)})$$

where the last inequality is due to the boundedness of the function values (cf. (30)). We can bound the last term as

$$2a_k \sum_{i=1}^{N} (\hat{\lambda}_i^{(k)} - \lambda + \hat{\lambda}_i^{(k)} - \hat{\lambda}_i^{(k-1)})^T g_i(\alpha_i^{(k)})$$

$$= 2a_k (\hat{\lambda}_i^{(k)} - \lambda)^T \left(\sum_{i=1}^{N} g_i(\alpha_i^{(k)})\right)$$

$$+ 2a_k \sum_{i=1}^{N} (\hat{\lambda}_i^{(k)} - \lambda)^T (g_i(\alpha_i^{(k)}) - g_i(\tilde{\alpha}_i^{(k)})) + 2a_k \sum_{i=1}^{N} (\hat{\lambda}_i^{(k)} - \hat{\lambda}_i^{(k-1)})^T g_i(\alpha_i^{(k)})$$

$$\leq 2a_k (\hat{\lambda}_i^{(k)} - \lambda)^T \left(\sum_{i=1}^{N} g_i(\alpha_i^{(k)})\right)$$

$$+ 4D \sqrt{P} L_g a_k \sum_{i=1}^{N} \|\alpha_i^{(k)} - \tilde{\alpha}_i^{(k)}\| + 2C a_k \sum_{i=1}^{N} \|\hat{\lambda}_i^{(k)} - \hat{\lambda}_i^{(k-1)}\|, \quad (A.9)$$

where in the last inequality, we have used $\hat{\lambda}_i^{(k)}, \lambda \in D$ and the compactness of $D$ (see (16)), and the Lipschitz continuity of $g_i$ (cf. (29)). Note that, since $L$ is linear in $\lambda$, we have

$$L(\hat{\alpha}^{(k)}, \lambda) = L(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) + (\lambda - \hat{\lambda}^{(k-1)})^T L_\lambda(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}). \quad (A.10)$$

where $\hat{\alpha}^{(k)} = ((\hat{\alpha}_1^{(k)})^T, \ldots, (\hat{\alpha}_N^{(k)})^T)^T$ and $L_\lambda(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) = \sum_{i=1}^{N} g_i(\hat{\alpha}_i^{(k)}).$ By combining (A.8), (A.9), (A.10) and (44) in Lemma 3, we obtain (47).
We first prove that relation (48) holds for the perturbation points $\hat{\alpha}_i^{(k)}$ and $\hat{\beta}^{(k)}$ in (42) assuming that Assumption 4 is satisfied. Note that (42a) is equivalent to

$$\hat{\alpha}_i^{(k)} = \arg\min_{\alpha_i \in \mathcal{X}_i} \|\alpha_i - x_i^{(k-1)} + \rho_1 L_{x_i}(x_i^{(k-1)}, \hat{\lambda}^{(k-1)})\|^2, \quad i = 1, \ldots, N,$$

where $L_{x_i}(x_i^{(k-1)}, \hat{\lambda}^{(k-1)}) = \nabla f_i^T(x_i^{(k-1)})\nabla F(Ny^{(k)}) + \nabla g_i^T(x_i^{(k-1)})\hat{\lambda}^{(k-1)}$. By the optimality condition, we have that, for all $x_i \in \mathcal{X}_i$,

$$(x_i - \hat{\alpha}_i^{(k)})^T (\hat{\alpha}_i^{(k)} - x_i^{(k-1)} + \rho_1 L_{x_i}(x_i^{(k-1)}, \hat{\lambda}^{(k-1)})) \geq 0.$$ 

By choosing $x_i = x_i^{(k-1)}$, one obtains

$$(x_i^{(k-1)} - \hat{\alpha}_i^{(k)})^T L_{x_i}(x_i^{(k-1)}, \hat{\lambda}^{(k-1)}) \geq \frac{1}{\rho_1} \|x_i^{(k-1)} - \hat{\alpha}_i^{(k)}\|^2,$$

which, by summing over $i = 1, \ldots, N$, gives rise to

$$(x^{(k-1)} - \hat{\alpha}^{(k)})^T L_x(x^{(k-1)}, \hat{\lambda}^{(k-1)}) \geq \frac{1}{\rho_1} \|x^{(k-1)} - \hat{\alpha}^{(k)}\|^2.$$ 

Further write the above equation as follows

$$(x^{(k-1)} - \hat{\alpha}^{(k)})^T L_x(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \geq \frac{1}{\rho_1} \|x^{(k-1)} - \hat{\alpha}^{(k)}\|^2 - (x^{(k-1)} - \hat{\alpha}^{(k)})^T (L_x(x^{(k-1)}, \hat{\lambda}^{(k-1)}) - L_x(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)})) \geq \frac{1}{\rho_1} \|x^{(k-1)} - \hat{\alpha}^{(k)}\|^2 - \|x^{(k-1)} - \hat{\alpha}^{(k)}\| \times \|L_x(x^{(k-1)}, \hat{\lambda}^{(k-1)}) - L_x(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)})\|. \quad (A.11)$$

By (8), Assumption 3, Assumption 4 and the boundedness of $\hat{\lambda}^{(k-1)} \in \mathcal{D}$, we can bound the second term in (A.11) as

$$\|L_x(x^{(k-1)}, \hat{\lambda}^{(k-1)}) - L_x(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)})\| \leq \|\nabla F(x^{(k-1)}) - \nabla F(\hat{\alpha}^{(k)})\| + \|\hat{\lambda}^{(k-1)}\| \|\nabla g_1^T(x_1^{(k-1)}) - \nabla g_1^T(\hat{\alpha}_1^{(k)})\| \leq (G_F + D_\lambda \sqrt{\bar{F} G_{g}}) \|x^{(k-1)} - \hat{\alpha}^{(k)}\|, \quad (A.12)$$
where \(\| \cdot \|_F\) denotes the Frobenious norm. By combining (A.11) and (A.12), we obtain
\[
(x^{(k-1)} - \hat{\alpha}^{(k)})^T \nabla L_x(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \geq \left( \frac{1}{\rho_1} - (G_F + D_\lambda \sqrt{P G_g}) \right) \| x^{(k-1)} - \hat{\alpha}^{(k)} \|^2. \tag{A.13}
\]
Since \(L(x^{(k-1)}, \hat{\lambda}^{(k-1)}) - L(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \geq (x^{(k-1)} - \hat{\alpha}^{(k)})^T \nabla L_x(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)})\) by the convexity of \(L\) in \(x\), we further obtain
\[
L(x^{(k-1)}, \hat{\lambda}^{(k-1)}) - L(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \geq \left( \frac{1}{\rho_1} - (G_F + D_\lambda \sqrt{P G_g}) \right) \| x^{(k-1)} - \hat{\alpha}^{(k)} \|^2. \tag{A.14}
\]
On the other hand, by (42b), we know that
\[
\hat{\beta}^{(k)} = \text{arg min}_{\beta \in \mathcal{D}} \| \beta - \hat{\lambda}^{(k-1)} - \rho_2 \sum_{i=1}^N g_i(x_i^{(k-1)}) \|^2.
\]
By the optimality condition and the linearity of \(L\) in \(\lambda\), we have
\[
L(x^{(k-1)}, \hat{\beta}^{(k)}) - L(x^{(k-1)}, \hat{\lambda}^{(k-1)}) = -(\hat{\lambda}^{(k-1)} - \hat{\beta}^{(k)})^T \left( \sum_{i=1}^N g_i(x_i^{(k-1)}) \right) \geq \frac{1}{\rho_2} \| \hat{\lambda}^{(k-1)} - \hat{\beta}^{(k)} \|^2. \tag{A.15}
\]
Combining (A.14) and (A.15) yields (48).

Suppose that \(L(x^{(k-1)}, \hat{\beta}^{(k)}) - L(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \to 0\) and \((x^{(k-1)}, \hat{\lambda}^{(k-1)})\) converges to some limit point \((\hat{x}^*, \hat{\lambda}^*)\) as \(k \to \infty\). Since \(\rho_1 \leq 1/(G_F + D_\lambda \sqrt{P G_g})\), we infer from (48) that \(\| x^{(k-1)} - \hat{\alpha}^{(k)} \| \to 0\) and \(\| \hat{\lambda}^{(k-1)} - \hat{\beta}^{(k)} \| \to 0\), as \(k \to \infty\). It then follows from (42) and the fact that projection is a continuous mapping [51] that \((\hat{x}^*, \hat{\lambda}^*) \in \mathcal{X} \times \mathcal{D}\) satisfies
\[
\hat{x}_i^* = \mathcal{P}_\mathcal{X}\left( \hat{x}_i^* - \rho_1 \nabla f_i^T(\hat{x}_i^*) \nabla F \left( \sum_{i=1}^M f_i(\hat{x}_i^*) \right) + \nabla g_i^T(\hat{x}_i^*) \hat{\lambda}^* \right), \quad i = 1, \ldots, N,
\]
\[
\hat{\lambda}^* = \mathcal{P}_\mathcal{D}(\hat{\lambda}^* + \rho_2 \sum_{i=1}^N g_i(\hat{x}_i^*))
\]
which, respectively, imply that \(\hat{x}^* = \text{arg min}_{x \in \mathcal{X}} L(x, \hat{\lambda}^*)\) and \(\hat{\lambda}^* = \text{arg max}_{\lambda \in \mathcal{D}} L(\hat{x}^*, \lambda)\) i.e., \((\hat{x}^*, \hat{\lambda}^*)\) is a saddle point of problem (15).

\section*{APPENDIX D}
\section*{PROOF OF LEMMA 7}

By (47) in Lemma 4 and the fact of \(L(\hat{\alpha}^{(k)}, \lambda) = L(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) + (\lambda - \hat{\lambda}^{(k-1)})^T L_\lambda(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)})\), we have
\[
(\lambda - \hat{\lambda}^{(k-1)})^T g(\hat{\alpha}^{(k)}) \leq \frac{\tilde{c}_k}{2a_k} + \frac{1}{2a_k} \left( \sum_{j=1}^N \| \lambda_j^{(k-1)} - \lambda \|^2 - \sum_{i=1}^N \| \lambda_i^{(k)} - \lambda \|^2 \right), \tag{A.16}
\]
where \( g(\hat{\lambda}^{(k)}) = \sum_{i=1}^{N} g_{i}(\hat{\lambda}_{i}^{(k)}) \) and
\[
\tilde{c}_{k} \triangleq a_{k}^{2}NC_{g}^{2} + 2a_{k}(2\rho_{1}D_{\lambda}PL_{g}^{2} + C_{g})\|\hat{\lambda}_{i}^{(k)} - \hat{\lambda}^{(k-1)}\| + 4\rho_{1}ND_{\lambda}G_{T}\sqrt{PML_{g}L_{f}a_{k}}\|g_{i}^{(k)} - g_{i}^{(k-1)}\|.
\]
By following a similar argument as in [27, Proposition 5.1] and by (A.16), (16), (29) and (30), one can show that
\[
(\lambda - \hat{\lambda})^{T}g(x^{(k-1)}) \leq \frac{\tilde{c}_{k}}{2a_{k}} + \frac{1}{2a_{k}}\left(\sum_{j=1}^{N}\|\lambda_{j}^{(0)} - \lambda\|^{2} - \sum_{i=1}^{N}\|\lambda_{i}^{(k)} - \lambda\|^{2}\right)
+ 2N\sqrt{PD_{\lambda}L_{g}}\|x^{(k-1)} - \hat{\lambda}^{(k)}\| + NC_{g}\|\hat{\lambda}^{(k-1)} - \hat{\lambda}^{*}\|.
\] (A.17)
By taking the weighted running average of (A.17), we obtain
\[
(\lambda - \hat{\lambda})^{T}g(\hat{x}^{(k-1)}) \leq \frac{1}{A_{k}}\sum_{\ell=1}^{k}a_{\ell}(\lambda - \hat{\lambda})^{T}g(x^{(\ell-1)})
\leq \frac{1}{A_{k}}\sum_{\ell=1}^{k}\tilde{c}_{\ell} + \frac{1}{2A_{k}}\left(\sum_{j=1}^{N}\|\lambda_{j}^{(0)} - \lambda\|^{2} - \sum_{i=1}^{N}\|\lambda_{i}^{(k)} - \lambda\|^{2}\right)
+ 2N\sqrt{PD_{\lambda}L_{g}}\sum_{\ell=1}^{k}a_{\ell}\|x^{(\ell-1)} - \hat{\lambda}^{(\ell)}\| + NC_{g}\sum_{\ell=1}^{k}a_{\ell}\|\hat{\lambda}^{(\ell-1)} - \hat{\lambda}^{*}\|
\leq \frac{1}{A_{k}}\sum_{\ell=1}^{k}\tilde{c}_{\ell} + \frac{2ND_{\lambda}^{2}}{A_{k}} + 2N\sqrt{PD_{\lambda}L_{g}}\sum_{\ell=1}^{k}a_{\ell}\|x^{(\ell-1)} - \hat{\lambda}^{(\ell)}\| + NC_{g}\sum_{\ell=1}^{k}a_{\ell}\|\hat{\lambda}^{(\ell-1)} - \hat{\lambda}^{*}\|
\] (A.18)
\[
\triangleq \xi^{(k-1)},
\]
where the first inequality is owing to the fact that \( g(x) \) is convex, and the last inequality is obtained by dropping \(-\sum_{i=1}^{N}\|\lambda_{i}^{(k)} - \lambda\|^{2}\) followed by applying (16). We claim that
\[
\lim_{k\to\infty} \xi^{(k-1)} = 0.
\] (A.19)
To see this, note that the first and second terms in \( \xi^{(k-1)} \) converge to zero as \( k \to \infty \) since \( \lim_{k\to\infty} A_{k} = \infty \) and \( \sum_{\ell=1}^{\infty} \tilde{c}_{\ell} < \infty \). The term \( \frac{1}{A_{k}}\sum_{\ell=1}^{k}a_{\ell}\|\hat{\lambda}^{(\ell-1)} - \hat{\lambda}^{*}\| \) also converges to zero since, by Lemma 6, \( \lim_{k\to\infty} \|\hat{\lambda}^{(k)} - \hat{\lambda}^{*}\| = 0 \) and so does its weighted running average by [44, Lemma 3]. Similarly, the term \( \frac{1}{A_{k}}\sum_{\ell=1}^{k}a_{\ell}\|x^{(\ell-1)} - \hat{\lambda}^{(\ell)}\| \) also converges to zero since \( \lim_{k\to\infty} \|x^{(k-1)} - \hat{\lambda}^{(k)}\| = 0 \) due to (50).
Now let \( \lambda = \hat{\lambda} + \delta \frac{(g(\hat{x}^{(k-1)}))^{+}}{\|(g(\hat{x}^{(k-1)}))^{+}\|} \) which lies in \( \mathcal{D} \), since \( \|\lambda\| \leq \|\hat{\lambda}^{*}\| + \delta \leq D_{\lambda} \) by (17). Substituting \( \lambda \) into (A.18) gives rise to
\[
\delta\|g(\hat{x}^{(k-1)})\|^{+} \leq \xi^{(k-1)}.
\] (A.20)
As a result, the first term in (58) is obtained by taking \( k \to \infty \) in (A.20) and by (A.19).

To show that the second limit in (58) holds true, we first let \( \lambda = \hat{\lambda} + \delta \frac{\lambda^{(k-1)}}{\|\lambda^{(k-1)}\|} \in D \). By substituting it into (A.18) and by (16), we obtain \((\hat{\lambda}^{(k-1)})^T g(\hat{x}^{(k-1)}) \leq (\frac{D}{\delta}) \xi^{(k-1)} \) which, by taking \( k \to \infty \), leads to

\[
\limsup_{k \to \infty} (\hat{\lambda}^{(k-1)})^T g(\hat{x}^{(k-1)}) \leq 0. \tag{A.21}
\]

On the other hand, by letting \( \lambda = 0 \in D \), from (A.18) we have 

\[
-(\hat{\lambda}^{(k-1)})^T g(\hat{x}^{(k-1)}) \leq \xi^{(k-1)} + (\hat{\lambda}^{(k-1)})^T g(\hat{x}^{(k-1)}) \leq \xi^{(k-1)} + NC_g\|\hat{\lambda}^{(k-1)} - \hat{\lambda}^*\|.
\]

Since \( \lim_{k \to \infty} \xi^{(k-1)} = 0 \) and \( \lim_{k \to \infty} \|\hat{\lambda}^{(k)} - \hat{\lambda}^*\| = 0 \) by Lemma 6, it follows that \( \liminf_{k \to \infty} (\hat{\lambda}^{(k-1)})^T g(\hat{x}^{(k-1)}) \geq 0 \), which along with (A.21) yields the second term in (58).

### Appendix E

**Proof of Lemma 8**

The definition of \( \hat{\alpha}^{(k)} \) in (43) implies that

\[
g_i^T (\hat{\alpha}_i^{(k)}) \hat{\lambda}^{(k-1)} + (\hat{\alpha}_i^{(k)} - x_i^{(k-1)})^T \nabla f_i^T (x_i^{(k-1)}) \nabla \mathcal{F}(Ny_i^{(k-1)})
+ \frac{1}{2 \rho_1} \|\hat{\alpha}_i^{(k)} - x_i^{(k-1)}\|^2 \leq g_i^T (x_i^{(k-1)}) \hat{\lambda}^{(k-1)},
\]

which, by summing over \( i = 1, \ldots, N \), yields

\[
g^T (\hat{\alpha}^{(k)}) \hat{\lambda}^{(k-1)} + (\hat{\alpha}^{(k)} - x^{(k-1)})^T \nabla \tilde{\mathcal{F}}(x^{(k-1)})
+ \frac{1}{2 \rho_1} \|\hat{\alpha}^{(k)} - x^{(k-1)}\|^2 \leq g^T (x^{(k)}) \hat{\lambda}^{(k-1)}, \tag{A.22}
\]

where \( g(\hat{\alpha}^{(k)}) = \sum_{i=1}^N g_i^T (\hat{\alpha}_i^{(k)}) \). By substituting the decent lemma in [51, Lemma 2.1]

\[
\tilde{\mathcal{F}}(\hat{\alpha}^{(k)}) \leq \tilde{\mathcal{F}}(x^{(k-1)}) + (\hat{\alpha}^{(k)} - x^{(k-1)})^T \nabla \tilde{\mathcal{F}}(x^{(k-1)}) + \frac{G_{\tilde{\mathcal{F}}}}{2} \|\hat{\alpha}^{(k)} - x^{(k-1)}\|^2 \tag{A.23}
\]

into (A.22), we then obtain

\[
\left( \frac{1}{2 \rho_1} - \frac{G_{\tilde{\mathcal{F}}}}{2} \right) \|\hat{\alpha}^{(k)} - x^{(k-1)}\|^2 \leq L(x^{(k-1)}, \hat{\lambda}^{(k-1)}) - L(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)})
\]

which, after combining with (A.15), yields (60).

To show the second part of this lemma, let us recall (A.3) that \( \hat{\alpha}_i^{(k)} \) in (43) can be alternatively written as

\[
\hat{\alpha}_i^{(k)} = \arg \min_{\alpha_i \in \mathcal{X}_i} g_i^T (\alpha_i) \hat{\lambda}^{(k-1)} + (\nabla f_i^T (x_i^{(k-1)}) \nabla \mathcal{F}(Ny_i^{(k-1)}) + \frac{1}{\rho_1} (\hat{\alpha}_i^{(k)} - x_i^{(k-1)}))^T \alpha_i,
\]
which implies that, for all \( x_i \in \mathcal{X} \), we have

\[
g_i^T(\hat{\alpha}_i^{(k)}) \hat{\lambda}^{(k-1)} + (\nabla f_i^T(x_i^{(k-1)}) \nabla \mathcal{F}(N \hat{y}^{(k-1)}) + \frac{1}{\rho_1}(\hat{\alpha}_i^{(k)} - x_i^{(k-1)}))T(\hat{\alpha}_i^{(k)} - x_i^{(k-1)})
\leq g_i^T(x_i) \hat{\lambda}^{(k-1)} + (\nabla f_i^T(x_i^{(k-1)}) \nabla \mathcal{F}(N \hat{y}^{(k-1)}) + \frac{1}{\rho_1}(\hat{\alpha}_i^{(k)} - x_i^{(k-1)}))T(x_i - x_i^{(k-1)}).
\]

By summing the above inequality over \( i = 1, \ldots, N \), one obtains, for all \( x \in \mathcal{X} \),

\[
g^T(\hat{\alpha}^{(k)}) \hat{\lambda}^* + \nabla \mathcal{F}^T(x^{(k-1)})(\hat{\alpha}^{(k)} - x^{(k-1)}) + \frac{1}{\rho_1} \| \hat{\alpha}^{(k)} - x^{(k-1)} \|^2
\leq g^T(x) \hat{\lambda}^* + \nabla \mathcal{F}^T(x^{(k-1)})(x - x^{(k-1)})
\quad + \frac{1}{\rho_1} \sum_{i=1}^N (\hat{\alpha}_i^{(k)} - x_i^{(k-1)})(x_i - x_i^{(k-1)}) + (\hat{\lambda}^* - \hat{\lambda}^{(k-1)})(g(\hat{\alpha}^{(k)}) - g(x))
\leq g^T(x) \hat{\lambda}^* + \mathcal{F}(x) - \mathcal{F}(x^{(k-1)}) + \frac{2D_x}{\rho_1} \sum_{i=1}^N \| \hat{\alpha}_i^{(k)} - x_i^{(k-1)} \| + 2C_g \| \hat{\lambda}^* - \hat{\lambda}^{(k-1)} \|
\]

where we have utilized the convexity of \( \mathcal{F} \) (Assumption 3), boundedness of \( \mathcal{X} \), and the constraint functions (cf. Assumption 2 and (30)) in obtaining the last inequality. By applying (A.23) to the above inequality and by the premise of \( 1/\rho_1 \geq G_\mathcal{F} > G_\mathcal{F}/2 \), we further obtain, for all \( x \in \mathcal{X} \),

\[
\mathcal{L}(\hat{x}^*, \hat{\lambda}^*) \leq \mathcal{L}(x, \hat{\lambda}^*) + \frac{2D_x}{\rho_1} \sum_{i=1}^N \| \hat{\alpha}_i^{(k)} - x_i^{(k-1)} \|
\quad + 2C_g \| \hat{\lambda}^* - \hat{\lambda}^{(k-1)} \| + |\mathcal{L}(\hat{x}^*, \hat{\lambda}^*) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^*)|, \quad (A.24)
\]

in which one can bound the last term, using (34), (27), (29) and (16), by

\[
|\mathcal{L}(\hat{x}^*, \hat{\lambda}^*) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^*)| \leq (L_\mathcal{F} + ND_\lambda \sqrt{P}L_g)\| \hat{x}^* - \hat{\alpha}^{(k)} \|. \quad (A.25)
\]

Suppose that \( \mathcal{L}(x^{(k-1)}, \hat{\beta}^{(k)}) - \mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^{(k-1)}) \to 0 \) and \( (x^{(k-1)}, \hat{\lambda}^{(k-1)}) \) converges to some limit point \((\hat{x}^*, \hat{\lambda}^*)\) as \( k \to \infty \). Then, by (60) and since \( 1/\rho_1 \geq G_\mathcal{F} \), we have \( \|(x^{(k-1)}, \hat{\lambda}^{(k-1)}) - (\hat{\alpha}^{(k)}, \hat{\beta}^{(k)})\| \to 0 \), as \( k \to \infty \). Therefore,

\[
\lim_{k \to \infty} \left( \frac{2D_x}{\rho_1} \sum_{i=1}^N \| \hat{\alpha}_i^{(k)} - x_i^{(k-1)} \| + 2C_g \| \hat{\lambda}^* - \hat{\lambda}^{(k-1)} \| + |\mathcal{L}(\hat{\alpha}^{(k)}, \hat{\lambda}^*) - \mathcal{L}(\hat{x}^*, \hat{\lambda}^*)| \right) = 0.
\]

Thus, it follows from (A.24), (A.25) and the above equation that \( \mathcal{L}(\hat{x}^*, \hat{\lambda}^*) \leq \mathcal{L}(x, \hat{\lambda}^*) \) for all \( x \in \mathcal{X} \). The rest of the proof is similar to that of Lemma 5.
