First report of Edwardsiellosis in cage-cultured sharpsnout sea bream, Diplodus puntazzo from the Mediterranean

Pantelis Katharios1*, Constantina Kokkari1, Nancy Dourala2 and Maria Smyrli1

Abstract

Background: Edwardsiella tarda, is a serious bacterial pathogen affecting a broad range of aquaculture fish species. The bacterium has also been reported as a human pathogen, however recent studies have dissociated the fish pathogenic Edwardsiella from those isolated from humans by placing them in a new species, E. piscicida. Here we report the first case of Edwardsiellosis in cultured sharpsnout sea breams, Diplodus puntazzo in Greece.

Case presentation: The disease has affected cultured sharpsnout sea breams of a commercial fish farm in a single location in East Greece. Two populations of sharpsnout sea breams stocked in two consecutive years in floating cages presented signs of disease which included nodules and abscesses in spleen and kidney, morbidity and cumulative mortality reaching 5.3 %. Using microbiological, biochemical and molecular tools we have identified Edwardsiella sp. as the main aetiological factor of the disease. Following phylogenetic analysis the bacterial isolates are grouped with the newly described Edwardsiella piscicida species.

Conclusions: This is the first report of Edwardsiellosis in this species but most importantly in sea cage-cultured fish in the Mediterranean which may pose a serious threat for aquaculture fish species in this region.

Keywords: Edwardsiella, Bacterial disease, Aquaculture, Fish

Background

Edwardsiella tarda is a serious bacterial pathogen affecting a wide range of fish species mostly in warm waters [1]. It is a Gram negative, motile bacterium of the Enterobacteriaceae family which can be intracellular during infection [2–4] making it less vulnerable to antibiotic treatment [5]. Its importance as a fish pathogen has been gaining increasing interest lately as it is associated with heavy losses in both freshwater and marine cultured fish but also because it can infect humans [6].

The bacterium is responsible for important economic damages in the aquaculture industry of the USA and Asia [5]. In Europe there are few sporadic reports of disease outbreaks in cultured turbot, Scophthalmus maximus (L) mainly from the Atlantic coast in the Gulf of Biscay [7–9] while in the Mediterranean, E. tarda has been isolated from diseased feral European eels, Anguilla anguilla (L.) from a coastal freshwater lagoon in Spain [10].

Sharpsnout sea bream, Diplodus puntazzo (Walbaum) is a well-appreciated sparid which has been considered for many years as one important candidate for the diversification of the Mediterranean aquaculture. Its production however remains low [11] mostly due to the vulnerability of species to various infectious and non-infectious diseases [12–14].

In this communication we report the isolation and partial characterization of E. tarda from diseased cultured sharpsnout sea breams. To our knowledge, this is the first isolation of the pathogen in Greece and from this host but more importantly the first report of E. tarda from cage-cultured marine fish in the Mediterranean.

Case presentation

The disease has affected cultured sharpsnout sea breams of a commercial fish farm in a single location in East Greece (Saronikos bay). Two populations of sharpsnout sea breams stocked in two consecutive years into 4
floating cages presented signs of disease. Each cage was stocked with approximately 50–55,000 fish. Two outbreaks of Edwardsiellosis were recorded, the first in October 2013 and the second in July 2014. Table 1 summarizes the production data of the affected stocks and the mortalities observed.

Diseased fish exhibited nodules and abscesses in spleen and kidney (Fig. 1). Pure colonies with identical morphology were obtained at the site by the fish vet of the fish farm in 10 % horse blood Agar (Oxoid) from the kidneys of approximately 30 fish exhibiting signs of distress in each incidence. The initial presumptive diagnosis was performed at the fish farm using API20E bacterial identification kit (BioMerieux, France) on 8–10 pure bacterial colonies from each incidence \( (n = 18) \). The API profile of all isolates was similar with variability only in the \( \text{H}_2\text{S} \) production. Other apparently healthy fish species cultured separately in different cages at the same site of the fish farm including gilthead sea bream, Sparus aurata, European sea bass, Dicentrarchus labrax, meagre, Argyrosomus regius and red porgy, Pagrus pagrus were also sampled \( (n = 20 \text{ per fish species}) \) for bacteriological examination (bacterial cultures in blood agar) during the outbreaks and were negative for \( E. \text{tarda} \). The fish were treated successfully following oral administration of oxolinic acid in feed \( (50 \text{ mg kg}^{-1} \text{ biomass for 7 consecutive days}) \).

Pure cultures of two strains (EtS1 and EtS2) isolated from sharpsnout sea bream from each two incidences were sent to the laboratories of HCMR for further characterization. Both isolates formed small distinct colonies. The bacteria were characterized and identified biochemically with BIOLOG GEN III and API20E systems according to manufacturers’ instruction and molecularly using PCR amplifying Edwardsiella sp. specific \( \text{gyrB} \) gene coupled with 16 s sequencing [15, 16]. The 16 s rRNA sequence data of the two strains have been deposited in NCBI GenBank under the accession numbers KP729431 and KP729432. In addition, the two strains were screened for the presence of selected virulence genes \( (\text{citC}, \text{fimA}, \text{gadB}, \text{katB}, \text{mukF} \text{ and } \text{esrB}) \) with PCR [17, 18]. All primers used are presented in Table 2.

The isolates were Gram negative, non-motile, oxidase negative, rods, identified as \( E. \text{tarda} \) with 55 % probability using BIOLOG GENIII. They could utilize several carbon sources such as sugars (maltose, glucose, N-Acetyl-D-glycosamine, N-Acetyl-neuraminic acid, mannosone, fructose, glucose-6-PO\(_4\), fructose-6-PO\(_4\), serine), aminoacids (galacturonic acid, gluconic acid, glucuronic acid) and carboxylic acid (lactic acid). Both strains could not utilize arabinose, mannitol and sucrose and exhibited variability in \( \text{H}_2\text{S} \) production. They could not grow in salinity exceeding 4 % NaCl and they were resistant in acidic pH. They could grow in 20 and 25 °C with best growth at 30 °C.

Identification was further validated after amplification of \( \text{gyrB} \) gene which resulted in a PCR product at the expected size. All virulence genes assessed were present in the isolates (Fig. 2). Haemolysis was tested on horse and sharpsnout sea bream blood agar. The later was obtained from disease-free broodstock fish of the Institute of Marine Biology, Biotechnology and Aquaculture, HCMR. Strains \( E. \text{tarda} \) (DSM 30052) and \( E. \text{hoshinae} \) (DSM 13771) were used as negative controls and Aeromonas veronii strain (Aero1- HCMR pathogen collection) previously shown to be strongly haemolytic on fish blood.

### Table 1

| Cage | Date stocked | Age at stocking (months) | First outbreak (October 2013) | Second outbreak (July 2014) |
|------|--------------|--------------------------|------------------------------|------------------------------|
|      |              |                          | Water temperature: 23 °C     | Water temperature: 26 °C     |
|      |              |                          | Average weight at first outbreak (g) | Cumulative mortality (%) | Average weight at second outbreak (g) | Cumulative mortality (%) |
| 1    | April 2012   | 2                        | 323                          | 4,82                         | 336                          | 4,86                         |
| 2    | April 2012   | 2                        | 319                          | 5,30                         | 440                          | 5,30                         |
| 3    | July 2012    | 5                        | 292                          | 4,76                         | 441                          | 4,76                         |
| 4    | April 2013   | 2                        | 84                           | 2,23                         | 274                          | 2,23                         |
as positive control. Following 48 h incubation at 25 °C only the Aeromonas veronii control strain was positive for haemolysis.

Antibiotic susceptibility of the two isolates was determined with a disk diffusion method [19] on Mueller-Hinton agar for ampicillin (10 μg), oxytetracycline (30 μg), oxolinic acid (2 μg), flumequine (30 μg), florfenicol (30 μg) and sulphamethoxazole/trimethoprim (25 μg) as suggested for fish pathogens [20]. Inhibition diameter was recorded after 24 h incubation at 25 °C. Response was determined according to the breakpoints shown in Table 3.

Phylogenetic relationships of the two isolates were studied using 16 s rRNA gene. The taxonomic status, strain collection numbers and GenBank Accession numbers (http://www.ncbi.nlm.nih.gov/) of all used sequences are presented in Table 4. A total length of 721 bp sequences was used for the phylogenetic analyses. Genetic distances and Neighbor-joining analysis [21] were respectively estimated and performed in MEGA [22] under Tamura-Nei [23] model of evolution. Confidence of tree nodes was tested by bootstrap analyses with 1000 replicates. Both isolates were grouped with E. ictaluri and E. tarda strains isolated from fish (Fig. 3). Genetic distances between strains EtS1 and EtS2 was 0 %, while the mean genetic distance within the fish-clade was 0.002 % and overall mean distance for the genus was 0.005 %.

**Discussion**

This is the first report of Edwardsiellosis in aquaculture fish in Greece and one of the few in the Mediterranean. Edwardsiella tarda has been isolated from feral European eels, Anguilla anguilla from a coastal freshwater lagoon near Valencia in Spain very close to the Mediterranean Sea [10]. In addition, Edwardsielllosis has also been reported in the Mediterranean coast of Spain in cultured European seabass, Dicentrarchus labrax, with the bacterial isolate however resembling E. ictaluri [24]. Recently, the assignment of the fish pathogenic isolates to this species has been questioned by Abayneh et al. (2013) [25] who instead proposed a new species, E. piscicida. The phylogenetic analysis of the current stains indicate that they are indeed grouped with the strains isolated from other fish. Moreover the biochemical profile of the two isolates is consistent with the profile of E. piscicida type strain [25] with the exception of motility. Atypical non-motile virulent E. tarda have been isolated from marine fish in Japan [26]. Those strains however were able to utilize arabinose and mannitol unlike the strains described in the current study. Recently, atypical non-motile E. tarda strains affecting cultured turbot in China were described [27]. These strains were similar to those described in the current study since besides being non-motile they could also utilize mannose and fructose but not arabinose and mannitol. Whether the strains described herein are E. piscicida instead of E. tarda needs further investigation since taxonomy of the Edwardsiella genus has not yet been fully resolved. Edwardsiellosis is manifested as a typical acute bacterial septicaemia with external haemorrhages and petechiae in skin and fins and bloody ascites in the peritoneal cavity with liver, spleen and kidney congestions [1, 28]; however it is also associated with more sub-acute lesions such as abscesses and nodules in the visceral organs [8] as in this case. The impact of the disease and its manifestation in terms of external clinical signs may vary depending on fish species. Disease outbreaks occur at high water temperatures [1, 27] usually above 20 °C which is in accordance to the water temperature occurring during the disease outbreaks reported here. Mortality can be severe and is dependent on many different factors such as fish
species, age, environmental conditions, handling, stress etc. Host specificity seemed to be an important factor since of the four different species cultured at the specific fish farm only sharpsnout sea bream was affected. The two strains described in this study showed differences in the antibiotic sensitivity. EtS2 which was isolated at the second incidence was resistant to the potentiated sulfonamide SFT unlike EtS1 which was isolated at the first incidence, while both strains were resistant to ampicillin and sensitive to oxolinic acid and florfenicol. Antibiotic resistance is one of the greatest concerns in aquaculture and *Edwardsiella tarda* isolated from fish has shown that can be multi-drug resistant including resistance to trimethoprim and ampicillin [29]. Virulence of the *Edwardsiella* sp. isolates was not assessed based on in vivo experiments due to legal and ethical constraints concerning the use of animals but on their virulent gene repertoire. The current isolates contained the main virulent genes described in literature after thorough functional genomic analysis and screening of virulent and a-virulent *E. tarda* strains [17]. Those genes are implicated in virulence by either providing resistance to the bacterium

| Antibiotic | Resistant breakpoints (mm) | Intermediate | Sensitive | EtS1 | EtS2 | Sensitivity |
|------------|-----------------|-------------|---------|-----|-----|------------|
| SFT (25 μg) | r < 14          | 14 ≤ r ≤ 16 | r > 16  | 16–17 | 12–13 | S          |
| OXA (2 μg)  | r < 11          | 11 ≤ r ≤ 13 | r > 13  | 18–19 | 18–20 | S          |

| 568      | *Serratia proteamaculans* |                    |                   | NR074820      |
against host phagocyte killing activity (GadB, KatB) [17] indicating also ability for intracellular survival and replication which has been shown for this species [4], or providing the necessary tools for cell adhesion (fimA) [17] and penetration (esrB which encodes a regulator protein for type III secretion system) [18]. The presence of these genes together with the clinical signs of the disease and the absence of any other pathogen suggest that Edwardsiella sp. was the aetiological cause of the disease.

Conclusions

Edwardsiella sp. was isolated from diseased cultured sharpnout sea bream. It is the first report in this host but also the first report from cultured fish in the Mediterranean. The isolates, identified as E. tarda are phylogenetically closer to the newly described E. piscicida species. Although confined only to this species until now, the pathogen could potentially spread in other species and pose serious threat to the Mediterranean aquaculture industry.

Availability of supporting data

The data set supporting the results of this article is included within the article (See Table 4).

Submit your manuscript to BioMed Central and take full advantage of:

- Convenient online submission
- Thorough peer review
- No space constraints or color figure charges
- Immediate publication on acceptance
- Inclusion in PubMed, CAS, Scopus and Google Scholar
- Research which is freely available for redistribution

Submit your manuscript at www.biomedcentral.com/submit
