Towards $\mathcal{R}$-matrix construction of Khovanov-Rozansky polynomials
I. Primary $T$-deformation of HOMFLY

A. Anokhina and A. Morozov

ITEP, Moscow, Russia

ABSTRACT

We elaborate on the simple alternative [1] to the matrix-factorization construction of Khovanov-Rozansky (KR) polynomials for arbitrary knots and links in the fundamental representation of arbitrary $SL(N)$. Construction consists of two steps: with every link diagram with $m$ vertices one associates an $m$-dimensional hypercube with certain $q$-graded vector spaces, associated to its $2^m$ vertices. A generating function for $q$-dimensions of these spaces is what we suggest to call the primary $T$-deformation of HOMFLY polynomial – because, as we demonstrate, it can be explicitly reduced to calculations of ordinary HOMFLY polynomials, i.e. to manipulations with quantum $R$-matrices, what brings the story completely inside the ordinary Chern-Simons theory. The second step is a certain minimalization of residues of this new polynomial with respect to $T + 1$. Minimization is ambiguous and is actually specified by the choice of commuting cut-and-join morphisms, acting along the edges of the hypercube – this promotes it to Abelian quiver, and KR polynomial is a Poincare polynomial of associated complex, just in the original Khovanov’s construction at $N = 2$. This second step is still somewhat sophisticated – though incomparably simpler than its conventional matrix-factorization counterpart. In this paper we concentrate on the first step, and provide just a mnemonic treatment of the second step. Still, this is enough to demonstrate that all the currently known examples of KR polynomials in the fundamental representation can be easily reproduced in this new approach. As additional bonus we get a simple description of the DGR relation between KR polynomials and superpolynomials and demonstrate that the difference between reduced and unreduced cases, which looks essential at KR level, practically disappears after transition to superpolynomials. However, a careful derivation of all these results from cohomologies of cut-and-join morphisms remains for further studies.

Accordingly there are two steps: 

1. Associated a hypercube with \( N \) graded vector spaces, not cyclic complexes, what makes unnecessary the matrix-factorization routine and allows calculations close to CFT/string dualities. The study of knot polynomials is just at its infancy, but already a lot of hidden modular transformations. Thus the study of this theory is a natural step after recent breakthrough in instanton calculus [4]-[10] and establishing its relation to CFT [11]-[23] – and it indeed attracts a lot of new attention.

2. The difference from conventional KR construction of [30] is that for arbitrary \( N \) there are still vector spaces, not cyclic complexes, what makes unnecessary the matrix-factorization routine and allows calculations by modest means in reasonable time. Moreover, the results emerge as explicit functions of \( N \), while in the matrix-factorization approach one gets them for each particular \( N \) and after that look for an interpolation formula, see [52]-[76] and the Jones-Khovanov \((N=2)\) [26, 27, 47] polynomials.

In [1] a simple and practical construction was suggested to reproduce the KR polynomials in the fundamental representation – which can substitute the sophisticated matrix-model factorization procedure of [30] and make calculations for arbitrary \( N \) as simple as they are made now for the ordinary HOMFLY and superpolynomials [52]-[76] and the Jones-Khovanov \((N=2)\) [26, 27, 47] polynomials.

In fact [1] outlines the program, but leaves many details of the algorithm obscure (nothing to say about the proofs). The purpose of this paper is to make a next step and provide a more clear and constructive formulation of the procedure. The goal of [1] was to make the procedure for arbitrary \( N \) as close as only possible to that of [78] and [26] for \( N = 2 \), in the version of [27] and [47] (which we suppose the reader to be familiar with). Accordingly there are two steps:

(i) to a link diagram \( L \) with \( n_b \) and \( n_w \) black and white vertices (see [1, 47] for notational details) one associates a hypercube \( H^L \) with \( q \)-graded vector spaces over each of its \( 2^{n_b+n_w} \) vertices,

(ii) commuting morphisms along the edges (linear maps of degree \(-1\) between the spaces at the ends of the edge) – and KR is the Poincare polynomial of the associated complex.

The difference from conventional KR construction of [30] is that for arbitrary \( N \) there are still vector spaces, not cyclic complexes, what makes unnecessary the matrix-factorization routine and allows calculations by modest means in reasonable time. Moreover, the results emerge as explicit functions of \( N \), while in the matrix-factorization approach one gets them for each particular \( N \) and after that look for an interpolation formula, see [52]-[76] and the Jones-Khovanov \((N=2)\) [26, 27, 47] polynomials.

9 Beyond braids

9.1 Twist knots

9.2 2-component links from two antiparallel strands

9.2.1 \( p = 1 \): the Hopf link \( 2^1 \)

9.2.2 \( p = 2 \): the Solomon link in opposite orientation \( 4^1(v1) \)

9.2.3 \( p = 3 \): the 2-component link \( 6^2(v2) \) or \( L6a5 \)

9.3 The 3-component link \( L6a5 (6^1(v1) \) of [43]

9.4 Skein relations for primary polynomials \( \Psi \)

10 Table of KR polynomials

11 On properties of morphisms

12 Conclusion
[43] for detailed presentation and the most extensive set of examples within this standard framework. Comparing the *shapes* of our formulas with their counterparts in [43], one can easily appreciate the power and relevance of the new approach.

Another advantage is explicit understanding of vector spaces as associated with the cycles of the resolutions of the link diagram – exactly as at $N = 2$, only one of the two resolutions is slightly different and vector spaces are rather factor-spaces (what makes the story a part of generic non-linear algebra studies [51] and is of course conceptually close to the cyclic-complex viewpoint, but technically is considerably simpler). As at $N = 2$, morphisms are associated with the cut-and-join operators, which either glue the two cycles into one, or cut one into two (what puts the story into the context of matrix models and is conceptually close to matrix-factorization ideas, but again, much simpler technically).

Both steps were only outlined in [1] and additional effort is needed to make these ideas into a universally applicable and rigorous approach. In this paper we do it with the first step, while the second one is still illustrated with examples – but somewhat less trivial and systematic than in original presentation of [1]. Moreover, while already practical (as compared to matrix-factorization technique), the second step remains time-consuming, and one can think about alternative procedures of ”minimization” of the "primary $T$-deformation $\mathfrak{R}^L(q, T, N)$ of HOMFLY polynomial $H^L(q, N)$" – which will be the form in which we put the outcome of the first step. This hope provides to this step an additional value of its own – and at the same time the recent advances in HOMFLY calculus allow to calculate $\mathfrak{R}^L$ in quite a number of sufficiently representative examples.

In addition, in this presentation it gets clear, what is so special for the fundamental representation – and this understanding can help in the search for the definition of the colored Khovanov-Rozansky polynomials.

The paper is focused on the calculational side of the story, and the second step still suffers from conceptual loopholes, but it already provides an extremely powerful technical way to calculate Khovanov-Rozansky polynomial for arbitrary given knot or link. In particular, we immediately reproduce all the known answers\(^1\) from [43], as well as those for many torus and twist knots/links. In our presentation, we assume whenever needed familiarity with the by-now-standard approaches to evaluation of link/knot polynomials, surveyed in detail in [52]-[76], [47] and [1].

### 2 Generalization of Kauffman $\mathcal{R}$-matrix and the ”primary deformation” $\mathfrak{R}$ of HOMFLY polynomial

Conceptual origin of Khovanov’s approach is in the general categorification program. However, operationally it begins from the much simpler step: see, for example, [47]. After that one of them is weighted with additional deformation parameter $T$. Undeformed (HOMFLY\(^2\)) case is associated with $T = -1$ – this convention has its origin in cohomological interpretation of the procedure. Alternatively one can consider this is a natural version of $\beta$-deformation, which plays a big role in the contexts of Jack or MacDonald polynomials and of AGT relations [77].

While for $N = 2$ the relevant splitting of the $\mathcal{R}$-matrix (in the fundamental representation) is well established [78], its direct analogue for arbitrary $N$ is not so familiar. However, it is equally simple:

$$\mathcal{R} = \frac{1}{q} \left( I \otimes I - q \cdot [2]P_{11} \right),$$

$$\mathcal{R}^{-1} = q \left( I \otimes I - \frac{1}{q} [2]P_{11} \right) = - \left( [2]P_{11} - q \cdot I \otimes I \right) \quad (2.1)$$

where

$$P_{11} = \frac{\frac{1}{2} \cdot I \otimes I - \mathcal{R}}{[2]} \quad (2.2)$$

\(^1\) Agreement is with the third version of that paper, where misprints are corrected.

\(^2\) Usually, HOMFLY (or, HOMFLY-PT) polynomial is defined as an expansion in powers of $q$ and $A = q^N$ (strictly speaking, it is then indeed a polynomial only for knots and only in reduced case). In the present paper we consider it instead as a (Laurent) polynomial of $q$, with $N$ defining the spectrum of exponents – and then it is a polynomial both for knots and links and both in reduced and unreduced cases. Since this is the only meaning, ascribed to the term HOMFLY polynomial in the text below, this should not cause too much confusion. Accordingly, positivity will be understood as the properties of the coefficients of *these* expansion – and it is not literally the same as positivity of the coefficients of the double expansion in $q$ and $A$. In particular, all quantum numbers and their products are positive, e.g. $[N] = \frac{2^N - (-1)^N}{2^N - (-1)^N} = q^{N-1} + q^{N-3} + \ldots + q^{1-N}$, while related difference $A - 1/A$, as a (Laurent) polynomial in $A$, is not.
is projector on the [11] constituent of representation product \([1] \otimes [1] = [2] + [11]\). This is the standard \(R\)-matrix\(^3\) and its inverse in the fundamental representation \([1] = \Box\), satisfying the skein relation \(R - R^{-1} = -q + q^{-1}\).

Eq. (2.1) decompose both \(R\) and \(R^{-1}\) into linear combinations of two operators – unity \(I \otimes I\) and \([2]P_{11}\), and this gives rise to representation of HOMFLY polynomials a sum over vertices of the hypercube with selected initial vertex\(^4\) – exactly as described in [27, 47] and [1]. Following [1], we define the \(T\)-deformation as follows:

\[
A^{-1}R \rightarrow q^{N-1} \left( I \otimes I + (qT) \cdot [2]P_{11} \right) = q^{N}T \cdot R + q^{N-1}(1 + T) \cdot I \otimes I \\
AR^{-1} \rightarrow \frac{1}{q^{N}T} \left( [2]P_{11} + (qT) \cdot I \otimes I \right) = -(q^{N}T \cdot R)^{-1} + q^{1-N}(1 + T^{-1}) \cdot I \otimes I
\]

(2.3)

When \(T = -1\), we return to (2.1), but for \(T \neq -1\) all the three Reidemeister properties are lost: these quantities do not satisfy Yang-Baxter equations and are not even inverse of each other. Still, calculate knot polynomial \(\Psi(q,T,N)\) with such deformed expressions by the usual method of [52, 58, 68] and decompose the result as follows:

\[
\Psi(q,T,N) = \mathcal{P}(q,T,N) + (T + 1) \cdot \mathcal{Q}(q,T,N)
\]

(2.4)

so that both the \(\mathcal{P}\) and \(\mathcal{Q}\) are positive polynomials i.e. all the coefficients of expansion in powers of \(q\) and \(T\) – after quantum numbers are expanded in powers of \(q\) – are positive integers.

Of course, modulo \(T + 1\), this \(\Psi\) is just a power of \(T\) times the ordinary HOMFLY polynomial, a function of \(q\) and \(N\) only:

\[
\Psi_{\mathcal{E}}(q,T,N) = (-T)^{n_{\varepsilon}} \cdot H_{\mathcal{E}}(q,N) + \sum_{i}^{\mathcal{E}} \sum_{j}^{\mathcal{E}} n_{\varepsilon}(T + 1)^{i+j} T^{n_{\varepsilon} - n_{\varepsilon} - i} \cdot Q_{ij}(q,N)
\]

(2.5)

where \(Q_{ij}\) are just the fundamental HOMFLY polynomials, for the link diagrams with some \(i\) black and \(j\) white vertices of original \(L\) resolved in a trivial way. Original HOMFLY of \(L\) is actually the \(i = j = 0\) term of this sum. But this does not mean that \(\mathcal{P}\) coincides with \(H\). If

\[
\Psi = \sum_{i \geq 0} a_{i}(q,N)T^{i}
\]

(2.6)

then the simplest solution to (2.4) could seem to be just the the alternated sum of the coefficients \(a_{i}\), i.e. the ordinary \(T\)-independent HOMFLY polynomial

\[
H(q,N) = \sum_{i \geq 0} (-)^{i}a_{i}
\]

(2.7)

Indeed, the difference is divisible by \((T + 1)\):

\[
\Psi - H = (1 + T) \left( \sum_{j \geq 0} T^{j} \cdot \sum_{i \geq 1} (-)^{i}a_{i+j}(q,N) \right)
\]

(2.8)

This indeed provides a solution to (2.4), so that KR polynomial does not depend on \(T\) and just coincides with HOMFLY, \(\mathcal{P} = H\), only if the whole set of positivity conditions is satisfied:

\[
\mathcal{P} = H \iff \forall j \geq 0 \sum_{i \geq 1} (-)^{i}a_{i+j}(q,N) > 0 \quad \text{(as polynomials in } q)\)

(2.9)

i.e. all the coefficients in (2.8) are positive integers. Such examples exist (e.g., unknot), but usually this is not so. We emphasize that HOMFLY itself can be positive (Hopf link is the simplest example), but the would be \(Q\) is usually not – and this makes the problem far less trivial.

\(^3\)In our standard notation from [58] it would be rather

\[
\frac{1}{A} R = q^{-N} \left( I - (q - R) \right) = q^{1-N} \left( I \otimes I - \frac{1}{q}[2]P_{11} \right)
\]

where \(R\) has eigenvalues \(q\) and \(-q^{-1}\), corresponding to representations \([2]\) and \([11]\) respectively, and projector \(P_{11} = \frac{q-R}{q+q^{-1}}\). It satisfies \(P_{11}^{2} = P_{11}\) because of the skein (Hecke) relation \(R - R^{-1} = q - q^{-1}\). In the present text we actually change \(q \rightarrow q^{-1}\) to match the notation of [1] – and, actually, to simplify the formulas for KR polynomials.

\(^4\)Note that the factor \([2]\) in front of the projector is independent of \(N\) – it is rather the \(q\)-deformation of 2 in the relation \((I - 2\pi)^{2} = I\) for \(\pi^{2} = \pi\) between projectors and the roots of unity.
3 A concept of KR polynomial

Informally, KR polynomial is the "minimal possible" $P$. The need for minimization is that deformed (2.3) are no longer inverse of each other and do not satisfy Yang-Baxter relations, $\Psi(q, T, N)$ is not Reidemeister invariant and thus not really a link/knot polynomial. However, minimization – if uniquely defined – could cure this problem and provide a topologically invariant $P$.

The problem is that it is not so simple to define an unambiguous minimization – the simplest example below will be the unreduced polynomial for the Hopf link. At present one needs to apply a rather involved cohomological construction to fix the ambiguities – in a way, which is, perhaps, artificial. As surveyed in [47, 1], it involves reinterpretation of primary polynomial as a generating function of $q$-dimensions of graded vector spaces at the resolution-hypercube vertices and then evaluation of cohomologies of the differentials, made from the cut-and-join morphisms along the hypercube edges. Graded spaces and morphisms can be constructed explicitly and the problem is essentially that of the elementary linear algebra. This is what we referred to as the "second step" on the introduction. Since in the approach of [1] it is still not fully specified, below we continue to provide examples – which hopefully will help to understand a rigorous definition, to be further transformed into a computer algorithm, like it was already done at $N = 2$.

But as to the first step – the definition and construction of the primary $\Psi^c$ – it is now fully clear (it was not quite in [1]). It is also clear what is so special about the fundamental representation (when necessary we denote it by $\otimes$ subscript, but omit in most formulas): only in this case the product $\otimes \otimes = [2] + [11]$ contains just two irreducible representations – and one can naturally split $R$-matrix in two constituents, which provide two types of resolutions at every vertex of the knot/link diagram $L$. This is what gives rise to the hypercube of resolutions. The same logic, applied to higher representations would require a generalization, e.g. in the spirit of gerbe theory.

4 Plan of the paper

The rest of the paper consist of examples: for different kinds of link diagrams $L$ we provide the primary polynomials $\Psi^c$ and discuss both their (often ambiguous) minimization and the chain

$\text{hypercube } \rightarrow \text{morphisms a la [1]} \rightarrow \text{Abelian quiver} \rightarrow \text{KR complex} \rightarrow \text{its Poincare/KR polynomial}$

Examples cover all the known KR polynomials: they were found for knots and links with up to six intersections in [43], what generalizes some previous calculations in [81] and [82]. Our formulas are valid for arbitrary $N$, while some of the results in [43] were found only for $N \leq 4$ or even $N \leq 3$.

Formulas for particular knots/links from this list can be located in the present paper with the help of the following table:
The list of simplest prime (non-composite) knots and links

| [79] | [43] | Name | Braid word | Orientation | Our answer |
|------|------|------|-----------|-------------|------------|

| (v2) | \{1,2,3,2,2,−1,2,2,−3,2\} | \{1\} | (8.75) & (8.76) |
| L6n1 | 67   | (v2) | \{1,−2,1,2,−1,2\} | \{0,0\} | (6.66) |
| (v1) | (torus [3,3]) | \{1,2,1,2,1,2\} | \{1,0\} | (6.50) & (6.138) |

Fundamental superpolynomials [34, 50, 74] are also known for a number of more complicated examples, including all torus [55, 56, 57, 40] and twisted [62, 73, 75] knots/links. Relation between superpolynomials and KR polynomials can seem somewhat subtle [50]: the former depend on additional parameter A (the claim is that they can be 3-graded [34] and, perhaps, even 4-graded [72, 74] generalizations of the 2-graded KR polynomials), while KR polynomials depend on the group size N (for SL(N)) through the quantum numbers [N − p], and powers qN. Still, at least in simple examples (going far beyond the "thin" knots), relation is straightforward – through a change of variables

\[
q^N = a, \quad [N - p] = \frac{q^{2p} + a^2T}{q^{p-1}(1-q^2)a}
\]

(note that our q and a here are q and a from [56]). In this sense evaluation of KR polynomials in these examples is equivalent to evaluation of superpolynomials.

Since our approach is based on the use of the primary T-deformation (presumably, an avatar of generic β-deformation [77]) of HOMFLY, the complexity of our calculations naturally depends on the number m of strands – and in this paper we do not go beyond m = 2, 3, 4 (this is enough to handle most of the examples from [43], and the two exceptions can be studied by alternative means).

Arbitrary two-strand knots and links (they are all torus) are analyzed in sec.5, eqs.(5.61) and (5.62) For three-strand torus knots and links, see secs.6.3 and 8.4.

Already at the level of m = 3 strands, we encounter a lot of composite knots and links – and we demonstrate that their reduced KR polynomials are nicely factorized (as HOMFLY did), while unreduced KR polynomials do not seem to decompose in any simple way. For some examples of composites, see sec.6.4.2.

We also consider in sec.8.8 the celebrated example of the knot 9_{42}

9_{42} : \{1,1,1,−2,−1,−1,3,−2,3\}

and demonstrate how the non-minimal KR polynomials (8.81) & (8.82) emerge in this case.

Note that in [79] the HOMFLY polynomials for links are currently provided only for one of a few possible orientations – for other orientations see [80] and [43].
Our calculations get really simple and concise in sec.8, where we begin directly at the level of KR complex, omitting construction of the hypercube. However, we provide before that a detailed and slow hypercube-based description in ss.5-7, because it establishes clear links to original Khovanov formalism and is also needed to construct and study the morphisms along lines of [1].

5 2-strand examples

All the 2-strand knots and links are torus, and therefore they are labeled as \([2, n]\). For odd \(n = 2k + 1\) we get knots, for even \(n = 2k\) – two-component links. Exhaustive description of the corresponding superpolynomials (which in the 2-strand case coincide with KR polynomials) can be found, for example, in [55, 56, 57].

5.1 Unknot \([2, 1]\)

5.1.1 Primary deformation \(\mathfrak{P}^{[2, 1]}\) of HOMFLY polynomial \(H^{[2, 1]}\)

Making use of the definitions of quantum dimensions and traces,

\[
\text{Tr}_{[1]\otimes[1]} I \otimes I = [N]^2
\]

\[
[2] \text{Tr}_{[1]\otimes[1]} P_{11} = [N][N - 1]
\]

with \([N] = \frac{q^N - q^{-N}}{q - q^{-1}}\), we get from the prescription (2.3) the following primary \(T\)-deformation of HOMFLY polynomial \(H^{[2, 1]} = \text{Tr}_{[1]\otimes[1]} \mathcal{R}\):

\[
\mathfrak{P}^{[2, 1]} = \text{Tr}_{[1]\otimes[1]} q^{N-1} \left( I \otimes I + (qT)[2]P_{11} \right) = q^{N-1} \left( [N]^2 + qT[N][N - 1] \right)
\]

This deformation, however, is not topological invariant and does not really deserve a name of knot polynomial – the second step (2.4) is still needed to get a reasonable quantity: the KR polynomial \(\mathcal{P}\).

Still, before proceeding to this step, let us note that alternatively the same \(P^{[2, 1]}\) in (5.2) can be obtained from expansion like (2.5):

\[
\mathfrak{P}^{[2, 1]} = \text{Tr}_{[1]\otimes[1]} \left( -q^N T \mathcal{R} + q^{N-1}(1 + T) \cdot I \otimes I \right) = -T H^{[2, 1]} + (1 + T) q^{N-1} H^{[2, 0]} =
\]

\[
- T q^N \left( q^{-1} \frac{[N][N + 1]}{[2]} - q \frac{[N][N - 1]}{[2]} \right) + (1 + T) q^{N-1}[N]^2 = -T [N] + (1 + T) q^{N-1}[N]^2 =
\]

\[
q^{N-1}[N]^2 + T q^N [N][N - 1] \equiv [N] \cdot \mathfrak{P}^{[2, 1]}\]

Boxed is the contribution of the HOMFLY polynomial \(H^{[2, 1]}\), and \(P^{[2, 1]}\) differs from it by a contribution proportional to \((1 + T)\). Note, however, that in this particular case the boxed polynomial is not positive – therefore it can not play the role of KR polynomial.

5.1.2 The basic morphism and reduced KR polynomial

The primary \(T\)-deformation

\[
\mathfrak{P}^{[2, 1]}_r = q^{N-1}[N] + T q^N[N - 1]
\]

is a combination of two quantum dimensions, \([N]\) and \([N - 1]\) – of the two graded vector spaces \(\mathbb{C}^N\) and \(\mathbb{C}^{N-1}\), standing at the two points of the hypercube, which in this case is just a segment with a single edge. As a simplification and a minor abuse of notation, in what follows we denote the vector spaces by their dimensions \(\mathbb{C}^{N-k} \equiv [N - k]\) and deviate from this rule only when this can cause confusion.

\[
\begin{array}{ccc}
\mathbb{C}^N & \xrightarrow{\alpha} & \mathbb{C}^{N-1} = [N - 1] \\
\bigcirc & \xrightarrow{\beta} & \bigcirc
\end{array}
\]

HCube([2, 1])

8
In this case it is equally obvious, what it is: $\beta$ vertex, then we need another morphism,

$$\begin{align*}
\mathbb{C}^N &\xrightarrow{\alpha} \mathbb{C}^{N-1} : \\
\alpha (q^{N+1-2k}) &= q^{N-2k} \quad \text{for } 1 \leq k \leq N-1 \\
\alpha (q^{1-N}) &= 0
\end{align*}$$

(5.5)

Since $[N] = q[N-1] + q^{1-N}$, this morphism has non-trivial kernel, but a trivial coimage:

$$\begin{align*}
\ker(\alpha_{[N]\rightarrow[N-1]}) &= q^{1-N}, \\
\coim(\alpha_{[N]\rightarrow[N-1]}) &= 0
\end{align*}$$

(5.6)

Since for a one-dimensional hypercube there is just one differential and it coincides with the morphism, $d_0 = \alpha$, these formulas imply that the KR polynomial is

$$P_{r,[2,1]}^{[2,1]} = q^{N-1} \left\{ \dim_q \ker(\alpha_{[N]\rightarrow[N-1]}) + (qT) \cdot \dim_q \coim(\alpha_{[N]\rightarrow[N-1]}) \right\} = 1 = P_{r, \text{unknot}}$$

(5.7)

as it should be for the unknot.

In fact, this is the reduced polynomial, defined for $\bullet$ as initial vertex. If we consider instead $\circ$ as initial vertex, then we need another morphism, $\beta$ acting in the opposite direction, but still decreasing grading by one. In this case it is equally obvious, what it is:

$$\mathbb{C}^{N-1} \xrightarrow{\beta} \mathbb{C}^N : \quad \beta (q^{N-2k}) = q^{N-2k-1} \quad \text{for } 1 \leq k \leq N-1$$

(5.8)

This time it has vanishing kernel, but non-vanishing coimage $q^{N-1} \in [N]$, so that the corresponding KR polynomial is

$$P_{r,[2,1]}^{[2,1]} = \frac{1}{q^{N}T} \left\{ \dim_q \ker(\beta_{[N-1]\rightarrow[N]}) + (qT) \cdot \dim_q \coim(\beta_{[N-1]\rightarrow[N]}) \right\} = \frac{1}{q^{N}T} (0 + (qT) \cdot q^{N-1}) = 1 = P_{r, \text{unknot}}$$

(5.9)

and again reproduces the right answer for the unknot.

### 5.1.3 Unreduced KR polynomial

In this case we need morphisms of degree $-1$ between the bigger vector spaces $\mathbb{C}^N \otimes \mathbb{C}^N = [N]^2$ and $\mathbb{C}^N \otimes \mathbb{C}^{N-1} = [N][N-1]$. In fact, for $\mathbb{C}^N \otimes \mathbb{C}^N = [N]^2 \rightarrow \mathbb{C}^N \otimes \mathbb{C}^{N-1} = [N][N-1]$ we now have two obvious choices $\alpha_1 = \alpha \otimes I$ and $\alpha_2 = I \otimes \alpha$. However, both choices produce the same answer: for $\bullet$ as initial vertex

$$P^{[2,1]} = q^{N-1} \left\{ \dim_q \ker(\alpha_{[N]\rightarrow[N-1]}) \cdot [N] + (qT) \cdot \dim_q \coim(\alpha_{[N]\rightarrow[N-1]}) \cdot [N] \right\} = q^{N-1} \left\{ [N] \cdot \dim_q \ker(\alpha_{[N]\rightarrow[N-1]}) + (qT) \cdot [N] \cdot \dim_q \coim(\alpha_{[N]\rightarrow[N-1]}) \right\} = [N] = P_{\text{unknot}}$$

(5.10)

However, for the morphism in the opposite direction $\mathbb{C}^N \otimes \mathbb{C}^{N-1} = [N][N-1] \rightarrow \mathbb{C}^N \otimes \mathbb{C}^N = [N]^2$ we have just a single options $I \otimes \beta$, providing for KR polynomial with initial vertex $\circ$

$$P^{[2,1]} = \frac{1}{q^{N}T} \left\{ [N] \cdot \dim_q \ker(\beta_{[N-1]\rightarrow[N]}) + (qT) \cdot [N] \cdot \dim_q \coim(\beta_{[N-1]\rightarrow[N]}) \right\} = [N] = P_{\text{unknot}}$$

(5.11)

Note that

$$\mathcal{Q}^{[2,1]} = q^N [N][N-1]$$

(5.12)

is also a positive polynomial and – in this particular case – neither $P$ nor $Q$ depend on $T$.

Moreover, in this case

$$P^{[2,1]} = [N] \cdot P_{r,[2,1]}$$

(5.13)

though in general $\mathcal{P}$ and $\mathcal{Q}_r = [N]^{-1} \cdot \mathcal{Q}$ can provide KR polynomials, which are not related in such a simple way (though reduced and unreduced HOMFLY always are).
5.2 The main rules of $T$-reduction

Conversion of the primary polynomial (5.4) into KR polynomial (5.9) can be considered as certain reduction of its dependence on $T$.

The elementary $T$-reduction rule

$$\lbrack N \rbrack + (qT) \cdot \lbrack N - 1 \rbrack = q^{1-N} + (1 + T) \cdot q[N-1] \sim q^{1-N}$$

(5.14)

together with another one,

$$\lbrack N - 1 \rbrack + (qT) \cdot q[N - 1] = q^{2-N} + q^N T + (1 + T) \cdot q[N - 2] \sim q^{2-N} T + q^N T$$

(5.15)

will play the central role in all our calculations.

For unreduced polynomials there will be an additional $T$-reduction rule – to reduce factor $\lbrack N \rbrack$ rather than $\lbrack N - 1 \rbrack$ whenever the product $\lbrack N \rbrack \lbrack N - 1 \rbrack$ appears, we will see this for the first time in eq.(5.43) below.

Note that we need to use the term "reduction" in two different meanings: for $T$-reduction and for elimination of an extra $\lbrack N \rbrack$ factor in the primary polynomial – and these two reductions do not commute: $T$-reduction of reduced polynomial in general leads to "reduced KR polynomials" – something rather different from "unreduced KR polynomial", the $T$-reduction of unreduced polynomial, which usually is just not divisible by $\lbrack N \rbrack$ (it is rather a linear combination of $\lbrack N \rbrack$ and $(1 + q^{2N}T)$, which also gets proportional to $\lbrack N \rbrack$ when $T = -1$). In what follows we often omit $T$- when referring to $T$-reduction and hope that this abuse of terminology (like "reduction of reduced polynomial") will not cause additional misunderstanding.

5.3 Hopf link

5.3.1 Primarily deformed HOMFLY polynomial

In this case

$$P^{[2,2]} = \text{Tr}_{[1[1[1[2111] \cdot q^{2N-2} (I \otimes I + (qT)[2111])^2 = \text{Tr}_{[1[1[1[2111] \cdot q^{2N-2} (I \otimes I + (qT)(2 + qT[2])][2111]) =}$$

$$= q^{2N-2} ([N] + qT(2 + qT[2])[N][N - 1]) = [N] \cdot q^{2N-2} ([N] + 2[N - 1] \cdot (qT) + 2[N - 1] \cdot (qT)^2)$$

(5.16)

where we used the projector property $P^{[2,2]}_{[2111]} = P_{11}$.

5.3.2 Reduced KR polynomial

The hypercube is now two-dimensional, and morphisms in the case of initial vertex •• are:

$$[N] \xrightarrow{d_0} 2 \times [N - 1] \xrightarrow{d_1} [2][N - 1]$$

$$\begin{array}{c}
[N] \\
\uparrow \alpha \\
\downarrow \beta
\end{array}$$

$$\begin{array}{c}
[N - 1] \\
\uparrow \alpha \\
\downarrow \beta
\end{array}$$

$$\begin{array}{c}
[q[N - 1] \\
\downarrow \alpha
\end{array}$$

(5.17)
In other words, the two differentials are

\[
\begin{align*}
  d_0 &= \begin{pmatrix} \alpha \\ \alpha \end{pmatrix} = \begin{pmatrix} [N-1] \\ [N-1] \end{pmatrix} \\
  d_1 &= \begin{pmatrix} 0 & 0 \\ \beta & -\beta \end{pmatrix} = \begin{pmatrix} q[N-1] \\ q^{-1}[N-1] \end{pmatrix}
\end{align*}
\]

Clearly, \(d_1 d_0 = 0\), and

\[
\begin{align*}
  \text{Ker}(d_0) &= \text{Ker}(\alpha_{[N] \rightarrow [N-1]}) = q^{1-N}, \\
  \text{Im}(d_0) &= d_0(a[N]) = \begin{pmatrix} a[N-1] \\ a[N-1] \end{pmatrix} = \text{Ker}(d_1), \\
  \text{Im}(d_1) &= d_1 \left( \begin{pmatrix} a[N-1] \\ b[N-1] \end{pmatrix} \right) = \begin{pmatrix} 0 \\ (a-b)q[N-1] \end{pmatrix} \implies \text{CoIm}(d_1) = \begin{pmatrix} q[N-1] \\ 0 \end{pmatrix}
\end{align*}
\]

It is important here, that \(\beta_{[N-1] \rightarrow [N-1]}\) is cohomologically trivial. Parameters \(a\) and \(b\) are arbitrary, but they are the same in the two constituents of \(\text{Im}(d_0)\).

It follows, that

\[
\mathcal{P}_r^{[2,2]} = q^{2N-2} \left\{ \dim_q \text{Ker}(d_0) + (qT) \left( \dim_q \text{Ker}(d_1) - \dim_q \text{Im}(d_0) \right) + (qT)^2 \dim_q \text{CoIm}(d_1) \right\} =
\]

\[
q^{2N-2} \left\{ q^{1-N} + (qT)^2 \cdot q[N-1] \right\} = q^{N-1} + q^{2N+1} T^2[N-1]
\]

This can be compared with the reduced superpolynomial, eq.(136) of [56]:

\[
\sim 1 + q^2 T^2 \frac{q^2 + a^2 T}{1 - q^2}
\]

and matching implies that while \(q^N = a\), the quantum number should be substituted by a different rule:

\[
[N-1] \rightarrow q^2 + a^2 T \quad \text{a}(1 - q^2)
\]

\[\frac{q^2}{a(1 - q^2)}\]

instead of the naive, but not positive \(\frac{q^2}{q-\frac{a^2}{q}} = \frac{q^2 - a^2}{a(1 - q^2)}\).

5.3.3 Reduced KR polynomial for initial vertex \(\bullet\)

The hypercube is the same, but two of the four morphisms are different:

\[
\begin{align*}
  \begin{array}{c}
    [N-1] \\
    [N]
  \end{array} & \xrightarrow{\beta} \begin{array}{c}
    d_0 \Downarrow \quad \text{\(q[N-1]\)} \\
    [N] \oplus \[N-1] \quad \Downarrow d_0
  \end{array} & \begin{array}{c}
    [N-1] \\
    [N-1]
  \end{array} \\
  \begin{array}{c}
    [N-1] \\
    [N]
  \end{array} & \xleftarrow{\beta'} \begin{array}{c}
    d_1 \Downarrow \quad \frac{q[N-1]}{q} \\
    [N] \oplus [2][N-1] \quad \Downarrow d_1
  \end{array} & \begin{array}{c}
    [N-1] \\
    [N-1]
  \end{array}
\end{align*}
\]
Accordingly

\[
d_0 = \begin{pmatrix} \beta \\ 0 \\ \beta \end{pmatrix} = \begin{pmatrix} \beta \\ 0 \\ \beta \\ [N-1] \end{pmatrix}
\]

\[
d_1 = \begin{pmatrix} \alpha & 0 & -\beta \end{pmatrix} = \begin{pmatrix} \alpha & 0 & -\beta \\ [N] & q[N-1] & \frac{1}{q}[N-1] \end{pmatrix}
\]

(5.24)

With this choice \(d_1d_0 = 0\), and \(q[N-1]\) belongs to coimage of \(d_0\) and to the kernel of \(d_1\). For the other spaces we have:

\[
\frac{1}{q}[N-1] = \begin{cases} [N-2] \\ q^{1-N} \end{cases}
\]

From this picture it is clear that

\[
\text{Im}(d_1) = d_1(a[N-1]) = \begin{pmatrix} 0 \\ a[N-2] \\ b[q^{1-N}] \\ a[N-2] \\ b[q^{1-N}] \end{pmatrix}
\]

\[
\text{Ker}(d_2) = \begin{pmatrix} 0 \\ a[N-2] \\ b[q^{1-N}] \\ a[N-2] \\ c[q^{1-N}] \end{pmatrix} \oplus q[N-1]
\]

(5.25)

i.e. that \(\text{Ker}(d_1)/\text{Im}(d_0)\) consists of the two underlined items and has dimension \(q^{1-N} + q[N-1] = [N]\). Also it is clear that the coimage of \(d_1\) is empty. Therefore in this case the reduced KR polynomial is

\[
\frac{q^{N-1}}{q^N T} \left( 0 + (qT) \cdot [N] + (qT)^2 \cdot 0 \right) = [N] = \mathcal{P}_{\text{unknot}} = \mathcal{P}_r^{\text{unknot}} \cup \text{unknot}
\]

(5.26)

Similarly one can study the initial vertex \(\circ\circ\), which reproduces the Hopf KR polynomial \(\mathcal{P}_r^{[2,2]}\).
5.3.4 Unreduced $P^{[2,2]}$, initial point ••

Now the hypercube is

$$\begin{array}{c}
[N]^2 \xrightarrow{d_0} 2 \times [N][N-1] \xrightarrow{d_1} [2][N][N-1] \\
[N][N-1] \xrightarrow{\alpha_2} \xrightarrow{\beta_2} q^{[N][N-1]} \\
[N]^2 \xrightarrow{d_0} \oplus \xrightarrow{d_1} \frac{1}{q}[N][N-1] \\
[N][N-1] \xrightarrow{\alpha_2} \xrightarrow{-\beta_2} \\
\end{array}$$

and the morphisms can be understood just as $\alpha_2 = I \otimes \alpha$ and $\beta_2 = I \otimes \beta$. Since in this case the vector space $\mathbb{C}^N = [N]$ acts just as a sterile factor, this is enough to obtain the well-known answer from [43, 1]

$$P^{[2,2]} = [N] \cdot P^{[2,2]} = q^{N-1}[N] + q^{2N+1}T^2[N][N-1]$$

(5.28)

Decomposition (2.4) becomes

$$\begin{array}{c}
P^{[2,2]} = P^{[2,2]} + (1 + T) \cdot Q^{[2,2]}, \\
(1 + T) \cdot Q^{[2,2]} = (1 + T)^2 \cdot q^{2N-1}[N][N-1] \geq 0
\end{array}$$

(5.29)

5.3.5 Alternative unreduced KR polynomial: also minimal, but incorrect

Still, it is instructive to consider another option (this makes sense already because for all other knots and links $P \neq [N] \cdot P_r$). Instead of

$$d_0 = \left( \begin{array}{c}
I \otimes \alpha \\
I \otimes \alpha
\end{array} \right), \quad d_1 = \left( \begin{array}{c}
I \otimes \beta, \\
-I \otimes \beta
\end{array} \right) = \left( \begin{array}{c}
\beta_2, \\
-\beta_2
\end{array} \right)$$

(5.30)

in (5.27) one could try

$$\tilde{d}_0 = \left( \begin{array}{c}
\alpha \otimes I \\
I \otimes \alpha
\end{array} \right), \quad \tilde{d}_1 = \left( \begin{array}{c}
I \otimes \alpha, \\
-\alpha \otimes I
\end{array} \right) = \left( \begin{array}{c}
\alpha_2, \\
-\alpha_1
\end{array} \right)$$

(5.31)

Note that to have the property $\tilde{d}_1 \tilde{d}_0 = 0$ preserved, we need to use $\alpha$ rather than $\beta$ in $\tilde{d}_1$.

What happens at the first step can look optimistic:

$$\text{Ker}(\tilde{d}_0) = \text{Ker}(\alpha_1) \cap \text{Ker}(\alpha_2) = q^{1-N}[N] \cap [N]q^{1-N} = q^{2-2N}$$

(5.32)

gets much smaller than $\text{Ker}(d_0) = q^{1-N}[N]$ in (5.28). However, decrease of particular cohomology can not lead to a “smaller” version of KR polynomial, because (5.28) already saturates the Euler characteristic: has the same number of terms as HOMFLY polynomial, which can not be further diminished. Alternative polynomial can be either “bigger” or of the “same size” as $P^{[2,2]}$.

To understand (5.32) better, it can be convenient to introduce two different variables $q_1$ and $q_2$, so that $[N]^2$ is substituted by $[N]_1[N]_2$, and $\alpha_1$, $\alpha_2$ act on $[N]_1$ and $[N]_2$ respectively. Then the intersection of kernels looks more explicit:

$$q_1^{1-N}[N]_2 \cap q_2^{1-N}[N]_1 = (q_1q_2)^{1-N}$$
The action of constituents of $\tilde{d}_1$ is also easily defined in these terms:

$$[N]^2 \xrightarrow{d_0} 2 \times [N][N-1] \xrightarrow{\tilde{d}_1} [2][N][N-1]$$

Clearly,

$$\text{Im}(\tilde{d}_1) = [N-1]_1[N-1]_2,$$

and the middle of the complex we have

$$\text{Im}(\tilde{d}_0) = \tilde{d}_0 \left( a \cdot q_1 q_2 [N-1]_1[N-1]_2 + b \cdot q_1^{-1-N} q_2 [N-1]_2 + c \cdot q_1 [N-1][2] q_2^{-1-N} + d \cdot q_1^{-1-N} q_2^{-1-N} \right) =$$

$$= \left( q_2 [N-1]_1 \left( a [N-1]_2 + c q_2^{-1-N} \right) q_1 \left( a [N-1]_1 + b q_1^{-1-N} \right) [N-1]_2 \right) = \text{Ker}(\tilde{d}_1)$$

Thus $\text{Ker}(\tilde{d}_1)/\text{Im}(\tilde{d}_0) = \emptyset$ and

$$\tilde{P}^{[2,2]} = q^{2N-2} \left( q^{2N} + 0 \cdot (qT) + [N+1][N-1] \cdot (qT)^2 \right) = 1 + q^{2N} T^2 [N+1][N-1]$$

This time decomposition (2.4) is $\tilde{P}^{[2,2]} = \tilde{P}^{[2,2]} + (1 + T) \cdot \tilde{Q}^{[2,2]}$ with

$$\tilde{Q}^{[2,2]} = q^{2N-1} [N-1] \left( [N](1+T) + q^{1-N} (1-T) \right) = q^{2N-1} [N-1] \left( [N] + q^{1-N} \right) \left( q[N-1]T \right) > 0$$

Clearly, this structure, though positive, is more involved than in (5.29). Also $\tilde{P}^{[2,2]} \neq P^{[2,2]}$ even for $N = 2$, therefore $\tilde{P}^{[2,2]}$ does not reproduce the answer [79] for the Jones-Khovanov polynomial. However, internal reasons to prefer (5.28) over (5.36) are unclear at the moment.

5.4 Trefoil as a torus knot [2, 3]

In this case

$$P^{[2,3]} = \text{Tr}_{[1][1]} q^{3N-3} \left( I \otimes I + (qT)[2]P_{11} \right)^3 =$$

$$= \text{Tr}_{[1][1]} q^{3N-3} \left( I \otimes I + (3qT + 3q^2 T^2[2] + q^3 T^3 [2]) [2] P_{11} \right) =$$

$$= q^{3N-3} \left( [N]^2 + (3qT + 3q^2 T^2[2] + q^3 T^3 [2]) [N][N-1] \right),$$

$$P^{[2,3]}_{red} = [N]^{-1} \cdot P^{[2,3]} = q^{3N-3} \left( [N] + (3qT + 3q^2 T^2[2] + q^3 T^3 [2]) [N-1] \right)$$

5.4.1 Reduced KR polynomial

In reduced case the primary polynomial is decomposed as follows:

$$q^{3-3N} P^{[2,3]} = [N] + 3qT[N-1] + 3(qT)^2[2][N-1] + (qT)^3[2]^2[N-1] =$$

$$= \left( [N] + qT[N-1] \right) + (qT) \left( [N-1] + qT \cdot \frac{1}{q} [N-1] \right) + (qT)^2 \left( \frac{1}{q} [N-1] + qT \cdot \frac{1}{q^2} [N-1] \right) +$$

$$+ 2(qT)^2 \left( q[N-1] + qT[N-1] \right) + (qT)^2 \left( q[N-1] + qT \cdot q^2 [N-1] \right)$$

(5.39)
This decomposition corresponds to the following pattern of morphisms in the hypercube:

\[
\begin{array}{cccc}
3[N - 1] & \xrightarrow{d_1} & 3[2][N - 1] & \xrightarrow{d_2} & 2^2[N - 1] \\
\hline
[N] & \rightarrow & 3 \times [N - 1] & \rightarrow & 3 \times \frac{1}{q}[N - 1] & \rightarrow & \frac{1}{q^2}[N - 1] \\
\hline
[N] & \Rightarrow & [N - 1] & \rightarrow & \frac{1}{q}[N - 1] & \rightarrow & \frac{1}{q^2}[N - 1] \\
\end{array}
\]

(5.40)

In the bottom part of the table all arrows are one-to-one, i.e. have neither kernels nor coimages, except for just two, denoted by double lines. In more details, this is described by the following shape of the differentials:

\[
d_2 = \begin{pmatrix}
0 & 0 & 0 & \beta & 0 \\
\beta & 0 & 0 & 0 & 0 \\
0 & \beta & 0 & 0 & \beta \\
0 & 0 & \beta & 0 & \beta \\
\end{pmatrix}, \quad d_1 = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & -\beta & 0 & 0 \\
0 & 0 & 0 & -\beta & 0 \\
0 & 0 & 0 & 0 & \beta \\
\end{pmatrix}, \quad d_0 = \begin{pmatrix}
\alpha \\
\alpha \\
\alpha \\
\alpha \\
\end{pmatrix}
\]

(5.41)

Thus we obtain for reduced KR polynomial:

\[
P_{\text{red}}^{[2,3]} = q^{3N-3} \left( q^{1-N} + (qT)^2 \cdot q(q^{2-N} + q^N) \right) = q^{2N-2} \left( 1 + q^4T^2 + q^{2N+2}T^3 \right)
\]

(5.42)

what is the standard answer [43, 1].

5.4.2 Unreduced KR polynomial

In unreduced case the only difference will be with the second double-line arrow:

\[q[N][N - 1] \Rightarrow q^2[N][N - 1]\]

There are now two options for the morphism (see s.6.6.1 of [1] for a picture): one can either use the same (5.15), as in the reduced case:

\[[N] \cdot q[N - 1] \Rightarrow q^2[N - 1] \]

or apply instead its analogue for the N-dimensional space:

\[q[N - 1] \cdot [N] \Rightarrow q[N] \]

i.e.,

\[[N] + qT \cdot q[N] = q^{1-N} + q^{N+1}T + (1 + T) \cdot q[N - 1] \sim q^{1-N} + q^{N+1}T\]

(5.43)

Clearly, the second option decreases the resulting polynomial, and thus we should apply it get the minimal \(P^{[2,3]}\):

\[
P^{[2,3]} = q^{3N-3} \left( q^{1-N}[N] + (qT)^2 \cdot q(q^{1-N} + q^{N+1})[N - 1] \right) =
\]

\[= q^{2N-2} \left( [N] + q^3[N - 1] \cdot T^2 + q^{2N+3}[N - 1] \cdot T^3 \right) = q^{2N-2}[N] + q^{2N+1}T^2(1 + q^{2N})[N - 1]
\]

(5.44)
what is the standard answer from [43, 1].

Note that $P^{[2,3]} \neq [N] \cdot P_r^{[2,3]}$, but this property is restored for HOMFLY at $T = -1$, $H^{[2,3]} = [N] \cdot H_{r}^{[2,3]}$ – and the factor $[N]$ arises from the factor $(1 + q^{2N})[N - 1]$ at the r.h.s. of (5.44). This will work just the same way for all other 2-strand knots and links.

### 5.5 Generic knot $[2, 2k + 1]$

This time

$$\mathcal{Q}^{[2,2k+1]} = q^{(2k+1)(N-1)} \left(I \otimes I + (qT)[2]P_1\right)^{2k+1} = [N]^2 + \left(\sum_{i=1}^{2k+1} (qT)^i C_{2k+1}^j [2]^{i-1}\right) [N][N-1] \quad (5.45)$$

The pattern of morphisms in this general situation is described in s.6.7 of [1]. It is absolutely clear from the representative example of the 5-foil ($k = 2$):

$$\begin{align*}
[N] &\Rightarrow 5[N-1] \rightarrow \frac{10}{q}[N-1] \rightarrow \frac{10}{q^2}[N-1] \rightarrow \frac{5}{q^3}[N-1] \rightarrow \frac{1}{q^4}[N-1] \\
9q[N-1] &\Rightarrow 20[N-1] \rightarrow \frac{11}{q}[N-1] \rightarrow \frac{7}{q^2}[N-1] \\
q[N-1] &\Rightarrow 10q^2[N-1] \rightarrow 15q[N-1] \rightarrow 6[N-1] \Rightarrow 4q^3[N-1] \rightarrow 4q^2[N-1] \\
q^3[N-1] &\Rightarrow q^4[N-1]
\end{align*} \quad (5.46)$$

In each line the alternated sum of multiplicities is zero, therefore it is further decomposed into one-to-one maps an obvious way, e.g. the first line is in fact

$$\begin{align*}
[N] &\Rightarrow [N - 1] \rightarrow \frac{6}{q}[N - 1] \rightarrow \frac{6}{q^2}[N - 1] \rightarrow \frac{1}{q^3}[N - 1] \\
4[N - 1] &\rightarrow \frac{4}{q}[N - 1] \rightarrow \frac{4}{q^2}[N - 1] \rightarrow \frac{1}{q^3}[N - 1]
\end{align*} \quad (5.47)$$

The three double arrows in (5.46) stand for the three maps with non-trivial cohomologies, which contribute to KR polynomial

$$\mathcal{P}^{[2,5]} = q^{5N-5} \left( q^{1-N} \begin{array}{c}
\sim [N] + qT \cdot q[N-1] \\
\sim q[N-1]+qT \cdot q^2[N-1] \\
\sim q^3[N-1]+qT \cdot q^4[N-1]
\end{array} \right) + (qT)^2 \cdot q \begin{array}{c}
\sim [N]+qT \cdot q[N-1] \\
\sim q[N-1]+qT \cdot q^2[N-1] \\
\sim q^3[N-1]+qT \cdot q^4[N-1]
\end{array} + (qT)^4 \cdot q^3 \begin{array}{c}
\sim [N]+qT \cdot q^2[N-1] \\
\sim q[N-1]+qT \cdot q^2[N-1] \\
\sim q^3[N-1]+qT \cdot q^4[N-1]
\end{array} \quad (5.48)$$

$$\mathcal{P}^{[2,5]} = q^{5N-5} \left( q^{1-N} \begin{array}{c}
\sim [N]+qT \cdot q[N-1] \\
\sim q[N]+qT \cdot q^2[N-1] \\
\sim q^3[N]+qT \cdot q^4[N-1]
\end{array} \right) + (qT)^2 \cdot q \begin{array}{c}
\sim [N]+qT \cdot q[N-1] \\
\sim q[N]+qT \cdot q^2[N-1] \\
\sim q^3[N]+qT \cdot q^4[N-1]
\end{array} + (qT)^4 \cdot q^3 \begin{array}{c}
\sim [N]+qT \cdot q^2[N-1] \\
\sim q[N]+qT \cdot q^2[N-1] \\
\sim q^3[N]+qT \cdot q^4[N-1]
\end{array} \quad (5.49)$$

Of course, these two formulas are in accord with [43] and [1].

For general $k$ decomposition has just the same structure as in this example: from (5.45)

$$\begin{align*}
\mathcal{Q}^{[2,2k+1]} =& \ [N] + \left( \sum_{i=1}^{2k+1} (qT)^i \sum_{j=0}^{i-1} q^{1-i+2j} C_{2k+1}^i C_{i-1}^j \right) [N-1] = \\
= q^{1-N} + q[N-1] \sum_{j=0}^{2k} q^{2j} \left( \delta_{j0} + \sum_{i=j+1}^{2k+1} C_{2k+1}^i C_{i-1}^j T_i \right)
\end{align*} \quad (5.50)$$
Thus there are $2k + 1$ lines, which we label by index $j = 0, \ldots, 2k$. However, the alternated sum of coefficients in the line $j$, i.e. the value of the sum in brackets, evaluated at $T = -1$, does not vanish, but is rather equal to $(-)^{j+1}$: it is given by the coefficient in front of $x^j$ in the sum

$$
\sum_{i=1}^{2k+1} (-)^i C_{2k+1}^i (1 + x)^{i-1} = -1 + \left(1 - (1 + x)\right)^{2k+1} \frac{1}{1 + x} = -1 + x - x^2 + \ldots - x^{2k}
$$

(5.51)

In order to convert these sums to zero we just move one item from the lines with odd $j$ to adjacent line $j + 1$, exactly as in (5.46). Now each line can be decomposed into a combination of one-to-one maps, with the exception of the very first mapping in each even line. Hence

$$
P_r^{[2,2k+1]} = q^{(2k+1)(N-1)} \left( \frac{1}{[N] + qT} \sum_{\text{even } j=2}^{2k} \frac{q^{j-1} \left( q^{2-N} + q^{N-1} \cdot qT \right) \left( q^{2-N} + q^{N-1} \cdot qT \right)}{\sum_{j=1}^{2k} (q^2 T)^{2j}} \right) = q^{2k(N-1)} \left( 1 + \left( 1 + q^{2N-2} T \right) \sum_{j=1}^{k} (q^2 T)^{2j} \right)
$$

(5.52)

Unreduced case differs just by the change of equivalencies, from

$$
[N - 1] + (qT) \cdot q[N - 1] \sim q^{2-N} + q^{N} T
$$

(5.53)

to

$$
[N - 1]\left( [N][N - 1] + (qT) \cdot q[N][N - 1] \right) \sim \left( q^{1-N} + q^{N+1} \cdot T \right)[N - 1]
$$

(5.54)

so that

$$
P^{[2,2k+1]} = q^{(2k+1)(N-1)} \left( \frac{q^{1-N} [N]}{[N] + q^{2N} [N][N - 1]} + \sum_{\text{even } j=2}^{2k} \frac{q^{j-1} \left( q^{1-N} + q^{N} \cdot qT \right) \left( q^{1-N} + q^{N} \cdot qT \right)}{\sum_{j=1}^{k} (q^2 T)^{2j} (1 + q^{2N} T)} [N - 1] \right) = q^{2k(N-1)} \left( [N] + \frac{1}{2} \sum_{j=1}^{k} (q^2 T)^{2j} \left( 1 + q^{2N} T \right) [N - 1] \right)
$$

(5.55)

Note that the second piece of this formula does not contain a factor $[N]$, thus $P^{[2,2k+1]} \neq [N]P^{[2,2k+1]}$. However, this property should be restored when we return to HOMFLY polynomial, i.e. at $T = -1$. This is guaranteed by emergence of the new factor $(1 + q^{2N} T)$ at the place of $[N]$; at $T = -1$ we have

$$
(1 - q^{2N})[N - 1] = q[N](1 - q^{2N-2})
$$

(5.56)

### 5.6 Generic link $[2, 2k]$

The only difference from the case of 2-strand links is that now the number of lines is of different parity, and in the last line with $j = 2k - 1$ and there is an additional mismatch. This is clear from any example, say, $k = 3$:
instead of (5.46) we have

\[ [N] \implies 6[N-1] \implies \frac{15}{q}[N-1] \implies \frac{20}{q^2}[N-1] \implies \frac{15}{q^3}[N-1] \implies \frac{6}{q^4}[N-1] \implies \frac{1}{q^5}[N-1] \]

\[ 14q[N-1] \implies 40[N-1] \implies \frac{45}{q}[N-1] \implies \frac{24}{q^2}[N-1] \implies \frac{5}{q^3}[N-1] \]

\[ q[N-1] \implies 20q^2[N-1] \implies 45q[N-1] \implies 36[N-1] \implies \frac{10}{q^4}[N-1] \]

\[ 14q^3[N-1] \implies 24q^2[N-1] \implies 10q[N-1] \]

\[ q^3[N-1] \implies 6q^4[N-1] \implies 5q^5[N-1] \]

\[ q^5[N-1] \]

In addition to non-one-to-one mappings marked by \( \implies \) the last line is a new item in the box, not involved in any mappings at all. It provides an additional contribution, moreover, the one proportional to \([N-1]\). In this particular example we get:

\[
P_r^{(2,6)} = q^{5N-5} \left( \frac{q^{1-N}}{\sim[N]+qT\cdot q[N-1]} + (qT)^2 \cdot q \left( \frac{q^{2-N} + qT \cdot q^{N-1}}{\sim q[N-1]+qT \cdot q^2[N-1]} \right) + (qT)^4 \cdot q^3 \left( \frac{q^{2-N} + qT \cdot q^{N-1}}{\sim q^3[N-1]+qT \cdot q^4[N-1]} \right) \right)_1 + \frac{1}{q^5}[N-1] \]

\[ (5.57) \]

Note that all the terms are exactly the same as in (5.48) and (5.49) – except for additional contribution in the box.

This is of course true for arbitrary \( k \) and

\[
P_r^{(2k)} = q^{N-1} \cdot P_r^{(2k-1)} + q^{2k(N-1)}(qT)^{2k} \cdot q^{2k-1}[N-1] \]

\[ (5.52) \]

\[ = q^{2k(N-1)} \left( q^{1-N} + \sum_{j=2 \text{ even}}^{2k-2} q^{2j-1} T \left( q^{2-N} + q^{N-1} \cdot qT \right) \right) \]

\[ = q^{(2k-1)(N-1)} \left( 1 + \left( 1 + q^{2N-2} T \right) \sum_{j' = 1}^{k-1} (q^2 T)^{2j'} \right) \]

\[ (5.58) \]

and similarly in unreduced case,

\[
P^{(2k)} = q^{N-1} \cdot P^{(2k-1)} + q^{2k(N-1)}(qT)^{2k} \cdot q^{2k-1}[N][N-1] \]

\[ (5.55) \]

\[ = q^{2k(N-1)} \left( q^{1-N} + \sum_{j=2 \text{ even}}^{2k-2} q^{2j} T \left( q^{1-N} + q^N \cdot qT \right) \right) \]

\[ = q^{(2k-1)(N-1)} \left( qN + \frac{1}{q} \sum_{j' = 1}^{k-1} (q^2 T)^{2j'} \left( 1 + q^{2N} T \right) \right) \]

\[ (5.59) \]
For \( k = 1 \) we reproduce (5.20) and (5.28) for the Hopf link, for \( k = 2 \) we obtain:

\[
\mathcal{P}_r^{[2,4]} = q^{3N-3} \left( 1 + q^4T^2 + q^{2N+2}T^3 + q^{N+6}T^4 [N-1] \right),
\]

\[
\mathcal{P}^{[2,4]} = q^{3N-3} \left( [N] + q^3T^2(N+1) + q^{N+6}T^4 [N][N-1] \right)
\]

(5.60)

5.7 Evolution in \( k \), MacDonald dimensions and \( \gamma \)-factors

5.7.1 Conversion to evolution representation

Eqs. (5.52) and (5.58) can be rewritten in more familiar forms:

\[
\mathcal{P}_r^{[2k+1]} = q^{(2k+1)(N-1)} \left( q^{1-N} + q^{5-N}T^2 + q^{9-N}T^4 + \ldots + q^{4k+1-N}T^{2k} + \ldots \right)
\]

\[
= q^{2k(N-1)} \left( 1 - q^{4k+4}T^{2k+2} \right) + q^{2N+2}T^3 \left( 1 - q^{4k}T^{2k} \right) = \left( q^{2Nk} \left( -q^{2k} + \frac{q^{2N+2k}T^3}{1 - q^4T^2} \right) - (qT)^{2k} \frac{q^{1+2N+2k}T^3 + q^4T^2}{1 - q^4T^2} \right)
\]

(5.61)

and

\[
\mathcal{P}_r^{[2k]} = q^{N-1 \cdot \mathcal{P}_r^{[2k+1]} + q^{2k(N-1)}(qT)^{2k} \cdot q^{2k-1}[N-1] =}
\]

\[
= q^{(2k-1)(N-1)} \left( 1 - \frac{(qT)^{k\cdot q^{2k-1}[N-1]}}{1 - q^4T^2} \right) = \left( 1 - q^{2k} + \frac{q^{2N+2k}T^3}{1 - q^4T^2} \right) + (qT)^{2k} \left( q^{N-2}[N-1] - \frac{1 + q^{2N-2}T}{1 - q^4T^2} \right)
\]

(5.62)

what are the right answers from [56].

The crucial point here is that the polynomials for torus knots are just fragments of the geometrical progression in powers of \( q^2T \), with the length which grows linearly in \( k \) – and this the only place (except for a common power of \( q^k \)) where \( k \) enters the formulas. As to the additional term, added for links, it also depends on \( k \) through the power of the same \( q^2T \). This is what is responsible for reemergence of the Rosso-Jones-like formula [81, 56] at the level of KR polynomial – and justifies the simple form of the \( k \)-evolution, suggested in [56, 73].

5.7.2 Conversion to MacDonald dimensions and DGR-trick

Note, however, that formulas in [56] have very different structure: there reduced polynomials, as functions of \( N \), were linear combinations of MacDonald dimensions

\[
M_1^+ = \frac{\{A\}}{\{q\}} = \frac{q \cdot 1 - A^2}{A \cdot 1 - q^2} = \frac{q \cdot 1 + a^2T}{A \cdot 1 - q^2},
\]

\[
M_2^+ = \frac{\{AqT\}}{\{q^2\}} = \frac{q \cdot 1 - A^2q^2T^2}{A \cdot 1 - q^4T^2} = \frac{q \cdot 1 + a^2q^2T^3}{A \cdot 1 - q^4T^2},
\]

\[
M_1^* = \frac{\{A\}}{\{q^2\}} = \frac{q \cdot 1 - A^2}{A \cdot 1 - q^4} = \frac{q \cdot 1 + a^2T^2}{A \cdot 1 - q^4},
\]

\[
M_2^* = \frac{\{AqT\}}{\{q^4\}} = \frac{q \cdot 1 - A^2q^2T^2}{A \cdot 1 - q^8} = \frac{q \cdot 1 + a^2q^2T^3}{A \cdot 1 - q^8},
\]

(5.63)

where \( \{x\} = x - x^{-1} \) and \( A^2 = a^2T^2 = q^{2N}T \). Clearly, MacDonald dimensions are not polynomials, and their denominators depend essentially on the Young diagram. At the same time, in (5.61) and (5.62) there are common denominators, moreover, the same ones for knots and links. From (5.61) it immediately follows that

\[
\mathcal{P}_r^{[2k+1]} = q^{2Nk} \cdot \frac{A}{q} \left( q^{-2k} \frac{M_2^*}{M_1^*} \cdot \gamma_{\text{knot}} \cdot (qT)^{2k} \frac{M_1^*}{M_1^*} \right) \mathcal{P}_r^{[2k+1]} = q^{2Nk+2} \left( q^{-2k-1} \frac{M_2^*}{M_1^*} \gamma_{\text{knot}} \cdot (qT)^{2k+1} \frac{M_1^*}{M_1^*} \right)
\]

(5.64)

where

\[
\gamma_{\text{knot}} = T^2 \frac{1 - q^4}{1 - q^4T^2}, \quad \gamma_{\text{knot}} \cdot q^2T = q^2T \cdot \frac{1 - q^4}{1 - q^4T^2}.
\]

(5.65)

in agreement with [56].
However, for links the situation is more interesting. Like in (5.61), the r.h.s. of (5.62) also has all $k$-dependence concentrated in two powers, also of $q^{-1}$ and of $qT$ and is nicely described by $k$-evolution a la [73]. Moreover, the coefficient in front of $q^{-2k}$ is again Mac Donald dimension $M^s_k/M^s_1$. But for the coefficient in front of $(qT)^{2k}$ the story is different:

$$\text{for } [N-1] = q^{-N} \frac{q^2 - q^{2N}}{1 - q^2} \text{ there is no match: } q^{N-2}[N-1] - \frac{1 + q^{2N-2}T}{1 - q^4T^2} \neq \gamma_{\text{link}} \frac{M^s_k}{M^s_1} \quad (5.66)$$

with $N$-independent $\gamma$-factor. An equality would hold, if we substitute on the place of $[N - 1]$ another cohomologically-equivalent expression:

$$[N - 1] \rightarrow q^{-N} \frac{q^2 + q^{2N}T}{1 - q^2} = q^{-N} \frac{q^2 - q^{2N}}{1 - q^2} + q^{-N} \frac{(1 + T)}{1 - q^2} \quad (5.67)$$

Then

$$q^{N-2}[N-1] - \frac{1 + q^{2N-2}T}{1 - q^4T^2} \sim \frac{q^2 + q^{2N}T}{q^2(1 - q^2)} - \frac{1 + q^{2N-2}T}{1 - q^4T^2} = \frac{(1 - q^2T^2)(q^2 + q^{2N}T)}{(1 - q^2)(1 - q^4T^2)} \quad (5.68)$$

and we would get from (5.62)

$$p_r^{[2,2k]} \sim q \cdot q^{(2k-1)N} \cdot \frac{A}{q} \left( q^{-2k} \frac{M^s_k}{M^s_1} + \gamma_{\text{link}} \cdot (qT)^{2k} \frac{M^s_k}{M^s_1} \right) \quad (5.69)$$

with

$$\gamma_{\text{link}} = \frac{(1 + q^2)(1 - q^2T^2)}{1 - q^4T^2}, \quad (5.70)$$

again in perfect agreement with [56].

In general, the rule to be applied instead of (5.67) is (4.1),

$$q^N = a, \quad [N - p] \sim \frac{q^{2p} + a^2T}{q^{p-1}(1 - q^2)a} \quad (5.71)$$

and it is the way the DGR relation [50] between superpolynomials and KR polynomials is realized in general situation.

### 5.7.3 An origin of the $\gamma$-factors

The second "mystery" which we now understand a little better – is that of the $\gamma$-factors [56]. We see that the origin of $\gamma$-factors is exactly the desire to express the answer through Mac Donald dimensions – in "natural" variables $\gamma$-factors are not needed. The question is what are these natural variables.

We see, that KR polynomials are naturally expressed not through Mac Donald dimensions, but through quantum numbers like $[N - 1]$ – which, moreover, have only negative shifts. In this respect they are more similar to $M^s_1$ – where shift of $N$ is also negative, – but denominator in KR polynomials is $1 - q^4T^2$, not $1 - q^4$, what is a feature of $M^s_2$ rather than $M^s_1$.

Thus Mac Donald polynomials once again appeared to be partly adequate to description of knot polynomials: they clearly are related, especially for torus knots and links [56, 57], and they are clearly not absolutely adequate – as we just saw and as it is well known in the story of colored polynomials (see [83] and references therein).

### 5.7.4 Unreduced KR polynomials

Now we can check that unreduced polynomials can also be expressed through Mac-Donald dimensions – moreover, after the substitution (5.71) the difference from reduced polynomials disappear(!): it becomes again just a simple factor $M^s_1$ – a natural substitute of the factor $[N]$ for HOMFLY.
Applying (5.71) to (5.55) and (5.59), we get respectively:

\[
P^{[2,2k+1]} = q^{2k(N-1)} \left( [N] + \frac{1}{q} \sum_{j'=1}^{k} (q^2 T)^{2j'} \left( 1 + q^{2N} T \right) [N - 1] \right)
\]

\[
\sim q^{2(k-1)(N-1)} \frac{1 + q^{2N} T}{1 - q} \left( 1 + (q^2 T^2) \cdot \left( q^2 + q^{2N} T \right) \frac{1 - (q^2 T)^{2k}}{1 - q^4 T^2} \right) =
\]

\[
= q^{(2k-1)(N-1)} \frac{A}{q} M_1^+ \left\{ \left( \frac{1 + q^{2N} T (q^2 + q^{2N} T)}{1 - q^4 T^2} \right) - \frac{q^2 T^2 (1 - q^2) M_1^+ A}{1 - q^4 T^2} \right\} =
\]

\[
= q^{(2k-1)(N-1)} \frac{A^2 q^{2k}}{q^2} \left( q^{-2k} M_2^* - \tilde{\gamma}_{\text{kn}} \cdot (qT)^{2k} M_1^+ \right) \quad (5.64) \quad \frac{A}{q^N} \cdot M_1^+ P^{[2,2k+1]} (5.72)
\]

and

\[
P^{[2,2k]} = q^{(2k-1)(N-1)} \left( [N] + \frac{1}{q} \sum_{j'=1}^{k-1} (q^2 T)^{2j'} \left( 1 + q^{2N} T \right) [N - 1] + (q^2 T)^{2k} q^{N-2} [N] [N - 1] \right)
\]

\[
\sim q^{2(k-1)(N-1)} \frac{1 + q^{2N} T}{1 - q^2} \left( \frac{1 + q^{2N+2} T^3}{1 - q^4 T^2} + (q^2 T)^{2k} \frac{(1 - q^2 T^2)(q^2 + q^{2N} T)}{(1 - q^2)^2 (1 - q^4 T^2)} \right) =
\]

\[
= q^{2(k-1)(N-1)} \frac{A^2 q^{2k}}{q^2} \left( q^{-2k} M_2^* + (qT)^{2k} \frac{(1 + q^2)(1 - q^2 T^2)}{1 - q^4 T^2} M_1^+ \right) \quad (5.69) \quad \frac{A}{q^N} \cdot M_1^+ P^{[2,2k]} (5.73)
\]

i.e. indeed

\[
P^{[2,2k+1]} \sim q^{-N} A \cdot M_1^+ P^{[2,2k+1]} (5.71)
\]

\[
P^{[2,2k]} \sim q^{-N} A \cdot M_1^+ P^{[2,2k]} (5.74)
\]

Note that \( A^2 = a^2 T \) and it is \( a \), not \( A \), that is substituted by \( q^N \) according to (5.71).
6 3-strand braids

6.1 Combinations of projectors

In the 3-strand case there are two different \( \mathcal{R} \)-matrices, associated with the crossings of the first two and the last two strands, we naturally denote them as \( \mathcal{R} \otimes I \) and \( I \otimes \mathcal{R} \). These two \( \mathcal{R} \)-matrices do not commute, thus HOMFLY polynomial for generic 3-strand braid is

\[
H_{3}^{(a_1, b_1|a_2, b_2|...|a_n, b_n)} \sim \text{Tr}_{[I] \otimes [I] \otimes [I]} \left\{ (\mathcal{R} \otimes I)^{b_{n}} (I \otimes \mathcal{R})^{a_{n}} \ldots (\mathcal{R} \otimes I)^{b_{2}} (I \otimes \mathcal{R})^{a_{2}} \ldots (\mathcal{R} \otimes I)^{b_{1}} (I \otimes \mathcal{R})^{a_{1}} \right\} \tag{6.1}
\]

For HOMFLY itself the proportionality coefficient is \( q^{(a_1+b_1+...+a_n+b_n)N} \), but after the \( T \)-deformation (2.3) contributions from positive and negative \( a_i \) and \( b_i \) will be different.

After the substitution (2.3) we obtain a linear combination of terms, which include traces of products of alternating projectors:

\[
\text{Tr}_{[I] \otimes [I]} \ldots (I \otimes P_{11})(P_{11} \otimes I) \tag{6.2}
\]

with up to \( n \) factors in the product. To deal with them we should follow the standard procedure, outlined in detail in [58]: decompose the product of three fundamental representations in two ways:

\[
\begin{align*}
\begin{array}{ccc}
\left[ 1 \right] \otimes \left[ 1 \right] & \otimes \left[ 1 \right] & \\
\left[ 2 \right] + \left[ 11 \right] & \otimes \left[ 1 \right] & \\
\left[ 3 \right] + \left[ 21 \right] + \left[ 111 \right] & & \left[ 3 \right] + \left[ 21 \right] + \left[ 111 \right]
\end{array}
\end{align*}
\]

(6.3)

Projectors \( P_{11} \otimes I \) and \( I \otimes P_{11} \) are on the underlined subspaces in the left and the right columns respectively, where \([111]\) is the same, but \([21]\) is a linear combination of \([21]\) and \([21]'\), explicitly described by Racah coefficients, see [?, ?] for details. Therefore

\[
(I \otimes P_{11})(P_{11} \otimes I) = P_{11} + \left| \left| \left| [12] \right| \right| \right| < c < [12],
\]

\[
< [12] || [12] || = c = \frac{1}{[2]} \tag{6.4}
\]

and so on:

\[
(P_{11} \otimes I)(I \otimes P_{11})(P_{11} \otimes I) = P_{11} + \left| [12] \right| > c^2 < [12],
\]

\[
(I \otimes P_{11})(P_{11} \otimes I)(I \otimes P_{11})(P_{11} \otimes I) = P_{11} + \left| [12] \right| > c^3 < [12],
\]

\[
\ldots \tag{6.5}
\]

Here

\[
[12] = [11] \otimes [1] \in \left[ [1] \otimes [1] \right] \otimes [11],
\]

\[
[12] = [1] \otimes [11] \in [1] \otimes \left[ [1] \otimes [1] \right] \tag{6.6}
\]

For the 3-strand torus knots/links \([3, n]\) the braid word is \((a_1, b_1|a_2, b_2|...|a_n, b_n) = (1, 1)[1, 1]...[1, 1]\), and

\[
\mathfrak{B}^{[3, n]} = q^{2n(N-1)} \cdot \text{Tr}_{[I] \otimes [I]} \left( I \otimes I \otimes I + (qT)[2](P_{11} \otimes I + I \otimes P_{11}) + (qT)^2[2]^2(I \otimes P_{11})(P_{11} \otimes I) \right)^n \tag{6.7}
\]
6.2 Dimensions $v_{n,k}(q, N)$ of spaces for three-strand braids

In the case of three strands we can associate with each vertex of the hypercube (i.e. with a resolution of original link/knot diagram) a string $A^{i_0}B^{j_1}A^{i_1}B^{j_2} \ldots B^{j_k}$, where all powers $i_0, j_1, i_1, \ldots, j_k > 0$ and the sum $i_0 + j_1 + i_1 + \ldots + j_k = n$, i.e. $n$ be the number of non-trivially resolved (white) crossings, while $k$ is the number of jumps from $A$ to $B$ resolutions. Since in our calculations $A$ and $B$ are actually substituted by projectors times $[2]$, expression for above string is almost independent of the powers $i_0, \ldots, j_k$; it equals $[2]^m$ times the expression for $(AB)^k$, which depends only on $k$. We denote the contribution of this string by $v_{n,k}$.

There are $s_{L}^{n,k}$ vertices of each type, and the contribution of each vertex is $v_{n,k}$, so that the primary deformed reduced polynomial is

$$P_{L}^{r}(q, T, N) = \sum_{n,k} s_{L}^{n,k} v_{n,k} \cdot (qT)^{n} \cdot \dim_{L}^{r}(q, N) \quad \text{(6.8)}$$

Quantum (graded) dimensions $v_{n,k}$ depend on parameters $(q, T, N)$, but are independent of the choice of the $m = 3$-strand knot/link. They are equal to:

$$v_{0,0} = [N]^{2},$$
$$v_{n,0} = [2]^{n}D_{11} = [2]^{n-1}[N][N-1], \quad n > 0,$$
$$v_{n,k} = [2]^{n}D_{11}^{kk} + [2]^{-2k}D_{21} = [2]^{n-2k}[N-1][2]^{2[k][N-2] + [N+1]} = [2]^{n-2k}[N-1] \left\{ [N-1] + \left( \sum_{i=0}^{k-2} [2]^{2i} \right) \cdot [2][N-2] \right\}, \quad 0 < 2k \leq n \quad \text{(6.9)}$$

6.3 Torus links and knots: KR deformation of $H^{[3,n]} = \text{Tr}_{\bigotimes^{3}} \left( \mathcal{R}_{1} \mathcal{R}_{2} \right)^{n}$ and alike

6.3.1 Cycles diagram

In the case of three-strand torus knots all the hypercube vertices, i.e. colorings of the knot/link diagram, can be labeled by telling the positions of white vertices on the intersections of the first two and the last two strands: hypercube vertices are labeled by $(i_1 < \ldots < i_k | j_1 < \ldots < j_l)$

As explained in [1], the classical (at $q = 1$) values of dimensions $v$ are defined by the numbers of connected cycles, appearing in the corresponding resolution of the link diagram – and in our present case these numbers depend only on $k$ and $l$, on the numbers of white vertices at two kinds of intersections:

| $k$  | $l$  | # (cycles) |
|------|------|------------|
| even | even | 3          |
| even | odd  | 2          |
| odd  | even | 2          |
| odd  | odd  | 1          |

Dimensions $v$ are constructed from these numbers by taking appropriate linear combinations, reflecting the structure of the corresponding factor-spaces [1]. Moreover, for torus knots and links, these numbers can be easily quantized. In the following simple examples, we show how the numbers of cycles and then the dimensions $v$ are ascribed to hypercube vertices. A universal technique providing the rigorous quantization rules will be described in the next subsection 6.3.2.

**The unknot** $[3, 1]$:

| 2   | $[N]^{3}$ | $[N][N-1]$ |
| 3   | 1          | $[N][N-1]$ |
The trefoil $[3,2]$:

|   |   |   |     |   |
|---|---|---|-----|---|
| 1 | 2 | 2 |   |   |
| 2 | 1 | 2 |   |   |
| 3 |   |   |   |   |

$[N][N^2[N-1]]$ $[2][N][N-1]^{2}$ $[2][N][N-1]^{2}$ $[N][N-1]^{2}$ $[2][N][N-1][N-2]$

In the right table we explicitly wrote the sequences of resolutions $A = P_{11} \otimes I$ and $B = I \otimes P_{11}$, associated with the hypercube vertices (up to cyclic order, in order not to further overload the notation). An exhaustively detailed notation would be $(A \cdot I_r \cdot A \cdot B \cdot I_l \cdot I_r)$ where brackets denote the cyclic class. Then edges of hypercube connect vertices, differing by a single substitution $I_l \leftrightarrow A$ or $I_r \leftrightarrow B$. However, we abbreviate the notation to just $A^2B$, so that the pattern of edges gets a little more obscure in this table. Note that $A$ and $B$ are resolutions, not projectors, therefore one can not substitute $A^2$ by $A$.

The next step is the table of quantum dimensions of graded spaces at the hypercube vertices:
The primary polynomial is given by a trace of the following product with $x^T$ by consideration of primary $T$-deformed polynomials. The general technique for doing this is exactly the main suggestion of the present paper, and it and is provided by consideration of primary $T$-deformed polynomials.

One can see that already in these examples some dimensions $v$ are quantized in a rather sophisticated way.

6.3.2 Primary $T$-deformation $\mathcal{P}^{(3,n)}$ for generic 3-strand torus knot/link

The primary polynomial is given by a trace of the following product with $x = qT[2]$:

$$q^{-2n(N-1)\mathcal{P}^{(3,n)}} = \text{Tr}_{[1][1]\otimes^{3}} \left\{ \left( P_{12}^{\otimes 3} + x \cdot I \otimes P_{11} \right) \left( P_{12}^{\otimes 3} + x \cdot P_{11} \otimes I \right) \right\}^n =$$

$$= D_3 + 2D_{21} \cdot \left( \sum_{j=0}^{n} \frac{j!(n^2 - j)}{(2j)!} (cx)^j (1 + x)^{n-j} \right) + D_{111} \cdot (1 + x)^{2n} = \left( 6.10 \right)$$

$$= \left[ N \right] \left\{ \frac{[N+1][N+2] + (1 + qT[2])^{2n}[N-1][N-2]}{2[3]} + \frac{2[N-1][N+1]}{[3]} \cdot \left( \sum_{j=0}^{n} \frac{n(n+j-1)!}{(2j)![(n-j)!]} (qT)^j (1 + qT[2])^{n-j} \right) \right\} =$$

$$= \left[ N \right] \left\{ \left[ N \right]^2 + 2n[N][N-1](qT) + n \left( (n-1)[N+1] + (2n-1)[N-1] \right) [N-1](qT)^2 +$$

$$\quad + \frac{n(n-1)}{3} \left( (n-2)[N+1] + 2(2n-1)[N-1] \right) [2][N-1](qT)^3 +$$

$$\quad + \frac{n(n-1)}{12} \left( (n-2)(n-3)[N+3] + 9(n-1)(n-2)[N+1] + 18(n-1)^2 - n(n+1) \right) [N-1] + 2(2n-1)(2n-3)[N-3] \right) [N-1](qT)^4 \ldots \right\}$$
For $T = -1$ this coincides with [81, 56]

$$q^{2n}[N] \left\{ q^{-2n} \frac{[N+1][N+2]}{[2][3]} - \frac{[N+1][N-1]}{[3]} + q^{2n} \frac{[N-1][N-2]}{[2][3]} \right\} \text{ for knots, } n = 3k \pm 1,$$

$$q^{2n}[N] \left\{ q^{-2n} \frac{[N+1][N+2]}{[2][3]} + 2 \cdot \frac{[N+1][N-1]}{[3]} + q^{2n} \frac{[N-1][N-2]}{[2][3]} \right\} \text{ for links, } n = 3k \quad (6.11)$$

because $[N \pm k] = \frac{(Aq^{\pm k})}{(q)}$ and $\{k\} = \frac{(q)^{\pm 1}}{(q)}$, where $\{x\} = x - x^{-1}$.

### 6.3.3 Multiplicities $s_{m,k}^L$ for the torus links/knots $[3, n]$

In variance with $v_{k,m}$, the multiplicities $s_{m,k}^L$ depend on $L$. Now we describe them for the torus links/knots $[3, n]$, thus they depend on $n$:

$$s_{m,0} = C_n^m C_n^0 + C_n^0 C_n^m = 2 C_n^m = \frac{2 \cdot n!}{m!(n-m)!}, \quad 0 \leq m \leq n,$$

$$s_{m,1} = n^2 C_n^{m-2} = \frac{n \cdot n!}{(m-2)!(n-m+1)!}, \quad 2 \leq m \leq n + 1,$$

$$s_{m,2} = n^2(n^2 - 1) C_n^{m-4}, \quad 4 \leq m \leq n + 2,$$

$$s_{m,3} = \frac{n^2(n^2 - 1)(n^2 - 4)}{360} C_n^{m-6}, \quad 6 \leq m \leq n + 3,$$

$$s_{m,k} = 2 \prod_{i=0}^{k-1} \left( \frac{n^2 - i^2}{2i} \right) C_n^{m-2k} = \frac{2n \cdot (n+k-1)!}{(2k)!(m-2k)!(n+k-m)!}, \quad 2k \leq m \leq n + k \quad (6.12)$$

Thus dimensions (6.8) of the spaces in KR complex for 3-strand torus knots are:

$$\dim_m = \sum_{k=n-m}^{m/2} s_{m,k} v_{m,k} = [N-1] \left\{ [N-1] \cdot \left( 2q^2 \right)^{m-1} C_n^m + \sum_{k=1}^{m/2} \left( \frac{2q}{2} \right)^{m-2k} s_{m,k} \right\} +$$

$$+ [N-2] \cdot \left( \sum_{k=2}^{m/2} \left( \frac{2q}{2} \right)^{m-2k} s_{m,k} \right) + q^{-N} \cdot 2q^2 C_n^m \right\}, \quad m > 0 \quad (6.13)$$

For $m = 0$ the dimension is just $\dim_0 = [N]^2 = [N-1]^2 + 2q^2-N[N-1] + q^{2-2N}$. With these values of $s_{m,k}$ eq.(6.8) reproduces the primary polynomial (6.10). However, now it is decomposed into three parts, what is convenient to reveal the general structure of cohomologies for all $n$.

### 6.3.4 Unknot $[3, 1], n = 1$

In this case the dimensions of spaces in KR complex $v_0 \xrightarrow{d_0^+} 2v_{10} \xrightarrow{d_1^+} v_{21}$ are:

$$\dim_0 = v_{0,0} = [N]^2$$

$$\dim_1 = 2v_{1,0} = 2[N][N-1]$$

$$\dim_2 = v_{2,1} = [N-1]^2 \quad (6.14)$$

(with a minor abuse of notation we denote the constituent spaces of the complex and their dimensions by the same letters $v_{m,k}$, and identify $\oplus$ with $+$).

Since $[N]^2 = q^2[N-1]^2 + 2q^2-N[N-1] + q^{2-2N}$ and $[N][N-1] = q[N-1]^2 + q^{1-N}[N-1]$, we have the following decomposition of $\mathbb{F}^3_v^{[3,1]}$: 
\[ q^{2-2N} P_{r}^{[3,1]} = v_{00} + 2v_{10}(qT) + v_{21}(qT)^2 = [N]^2 + 2[N][N - 1] (qT) + [N - 1]^2 (qT)^2 = \]

\[
\begin{array}{c|c|c}
[N - 1] & q^2 & \rightarrow 2q \rightarrow 1 \\
q^{-N} & 2q^2 & \rightarrow 2q \\
\end{array}
\]

(6.15)

where the columns of the table are multiplied by powers of \((qT)\) and arrows stand for the cohomologically trivial sub-complexes of graded spaces, while cohomologies are boxed. In more complicated examples below we denote by \(\Rightarrow\) the differentials, which are not cohomologically trivial, and separate horizontal lines the cohomologically trivial and non-trivial chains. Double horizontal lines will separate transformation steps of the set of complexes, targeted at localizing its cohomologies.

Since in the case of \([3, 1]\) the only cohomologically non-trivial item is the boxed \(q^{2-2N}\), we obtain:

\[ P_{r}^{[3,1]} = q^{2N-2} \cdot q^{2-2N} = 1 \]

(6.16)

for reduced KR polynomial.

Since cohomologically trivial complex remains cohomologically trivial after multiplication by \([N]\), we get

\[ P^{[3,1]} = [N] \]

(6.17)

for the unreduced one.

### 6.3.5 Another initial vertex

In fact, one and the same hypercube describes link diagram \(\mathcal{L}\) with an arbitrary coloring of vertices – the graded vector spaces at the hypercube vertices are the same. What differs is the choice of initial vertex and morphisms along the edges, which all point away from initial vertex. In particular, the hypercubes for the two series \((R_1 R_2)^n\) and \((R_1 R_2^{-1})^n\) are the same – and it is instructive to consider them together.

In particular, the just discussed representation for the unknot \([3, 1] = (1, 1)\) can be compared with another representation for the unknot, \((1, -1)\), which gives rise to by the same hypercube, but different morphisms, KR complex and differentials. This time the complex is

\[
\begin{array}{c|c|c|c}
[N - 1] & q & \rightarrow q^2 + 1 \rightarrow 1 \\
q^{-N} & 2q^2 & \rightarrow 2q \\
\end{array}
\]

(6.18)

Now, \(q[N - 1] \Rightarrow q^2[N - 1]\) is cohomologically equivalent to \(q^{3-N} \Rightarrow q^N\), this should be further multiplied by \(q^{-N}\). Afterwards we add the term \(q^{2-2N}\) and get: \(q^{1-2N} \Rightarrow 1 + q^{2-2N}\), which is equivalent to just \(0 \Rightarrow 1\). Thus we obtain

\[ P_{r}^{1,-1} = \frac{1}{qT} \left( 1 \cdot (qT) \right) = 1 \]

(6.19)

while unreduced \(P^{1,-1} = [N]\).

### 6.3.6 Trefoil \([3, 2]\)

The KR complex is

\[
\begin{align*}
v_{00} & \xrightarrow{d_0} 4v_{10} \xrightarrow{d_1} 2v_{20} + 4v_{21} \xrightarrow{d_2} 4v_{31} \xrightarrow{d_3} v_{42}
\end{align*}
\]

(6.20)
and the generating function of its graded dimensions

\[
\begin{align*}
\dim_0 &= v_{0,0} = [N]^2 \\
\dim_1 &= 4v_{1,0} = 4[N][N-1] \\
\dim_2 &= 2v_{2,0} + 4v_{2,1} = 2[2][N][N-1] + 4[N-1]^2 \\
\dim_3 &= 4v_{3,1} = 4[2][N-1]^2 \\
\dim_4 &= v_{4,2} = [N-1]^2 + [2][N-1][N-2]
\end{align*}
\]

- the primary $T$-deformation of HOMFLY – can be written in the form of the following table:

\[
q^{4-4N}P^{[3,2]}_T = \boxed{q^{2-2N}} + [N-1] \times \begin{array}{c|ccc}
[N-1] & 2q^2 & 4q & 1 \\
[N-2] & & & (1) \\
& q & (2) & \\
[N-1] & q^2 & 4q & 6 \frac{4}{q} & (-1) \\
[N-2] & & \frac{1}{q} & (1) \\
q^{-N} & 2q^2 & 4q & 2 & (0) \\
q^{-N} & 2q^2 & (2) \\
\end{array}
\]

We added the last column – it lists the alternated sums of coefficients in every line. Then we underlined the terms, which are selected to contribute to the cohomologies (multiplicity of the contribution is expressed by the number of underlines). This selection is not always fully unique, and is adjusted to match the right answers, when they are known (for the simple links and knots), and then according to the general rule within the series, as usual in the evolution method [73]. The freedom is in fact severely restricted by the minimality of KR polynomial: this requires that there are no gaps in the would be cohomologies, thus the underlined items from adjacent lines are in adjacent columns, where $[N-1] \implies [N-2]$ is substituted by $q^{2-N} \implies 0$, and also restricts the choice of underlined items in non-adjacent lines (we shall see examples below).

Now we iteratively extract the cohomologically non-trivial part. First – pick it up from the underlined items:

\[
q^{2-2N} + [N-1] \times \begin{array}{c|ccc}
[N-1] & 2q^2 & 3q & 1 \\
[N-1] \times q^2 & 4q & 6 & \frac{3}{q} \\
q^{-N} & 2q^2 & 4q & 2 \\
\end{array}
\]

The upper part of the table is cohomologically trivial, the lower is not. Still, since $[N-1] \implies [N-2]$ is cohomologically equivalent to $q^{2-N} \implies 0$, it can be further diminished: first to

\[
q^{2-2N} + [N-1] \times \begin{array}{c|c}
q^{-N} & 2q^2 \ [2] \\
\end{array}
\]

and then to

\[
q^{2-2N} + [N-1] \times \begin{array}{c|c}
q^{-N} & q^2 \ [3] \\
\end{array}
\]

```
At the last step we recall the common factor \([N - 1]\) (and \([N][N - 1]\) in unreduced case) and further substitute
\[
[N - 1](q^2 \implies q^3) \quad \text{by} \quad q^{4 - N} \implies q^{N + 1}
\] (6.25)
and
\[
[N][N - 1](q^2 \implies q^3) \quad \text{by} \quad q^{3 - N}[N - 1] \implies q^{N + 2}[N - 1]
\] (6.26)
Thus
\[
P_r^{[3,2]} = q^{4N - 4}\left\{q^{2 - 2N} + q^{4 - 2N}(qT)^2 + q \cdot (qT)^3\right\} = q^{2N - 2}\left\{1 + q^4T^2 + q^{2N + 2}T^3\right\}
\] (6.27)
and
\[
P_r^{[3,2]} = q^{2N - 2}\left\{[N] + q^3[N - 1]T^2 + q^{2N + 3}[N - 1]T^3\right\}
\] (6.28)
Note that \(P_r^{[3,2]} \neq [N]P_r^{[3,2]}\) – this is because after multiplication by \([N]\) the irreducible cohomologically non-trivial complex can acquire a cohomologically trivial sub-complex, and thus cohomologies can get smaller – and KR polynomial gets "smaller": the difference \([N]P_r - P_r\) is a non-vanishing positive polynomial.

6.3.7 The figure-eight knot \(4_1\), \((R_1R_2^{-1})^2\)

This knot has the same three-strand knot diagram as the trefoil, but with two vertices of different color.

The KR complex is
\[
v_{20} \xrightarrow{d_0} 2v_{10} + 2v_{31} \xrightarrow{d_1} v_{00} + 4v_{21} + v_{42} \xrightarrow{d_2} 2v_{10} + 2v_{31} \xrightarrow{d_3} v_{20}
\] (6.29)
with the same dimensions \(v_{mk}\), and
\[
\left(\frac{q^{N - 1}}{q^{NT}}\right)^{-2} \cdot P_r^{4_1} = \boxed{q^{2 - 2N} \cdot (qT)^2 + \ldots}
\]

\[
\begin{array}{c|cccc}
[N - 1] & q^2 & 2q & 1 & 2q & q^2 \\
[N - 2] & q & & & + (1) \\
\hline
[N - 1] & 1 & 2q + \frac{q}{q} & q^2 + 4 & 2q + \frac{q}{q} & 1 \\
[N - 2] & \frac{q}{q} & & + (1) \\
\hline
q^{-N} & 1 & 2q & 2q^2 & 2q & 1 \\
q^{-N} & q^2 & & & (2)
\end{array}
\]
(6.30)
Since the table differs by permutation of columns, the alternated sums are the same as for the trefoil. Now the doubling of lines does not make much sense, and we begin from rewriting the table as
\[
\begin{array}{c|cccc}
[N - 1] & q^2 + 1 & 4q + \frac{q}{q} & q^2 + 5 & 4q + \frac{q}{q} & q^2 + 1 \\
[N - 2] & q + \frac{q}{q} & & + (2) \\
\hline
q^{-N} & q^2 + 1 & 2q & 2q^2 & 2q & q^2 + 1 \\
\end{array}
\]
(6.31)
Extracting the trivial exact subsequences, we get

| $[N - 1] \times$ | $q^2$ | $3q$ | $2$ | $q^2$ | $2q$ | $1$ |
|-------------------|-------|------|-----|-------|------|-----|
| $[N - 1] \times$ | $1$   | $\frac{1}{q}$ | $2$ | $\frac{2}{q}$ |   |
| $[N - 1] \times$ |       |      |     |       |     |    |
| $[N - 1] \times$ | $q + \frac{1}{q}$ | $1$ | $2q$ | $q^2$ |   |
| $q^{-N} \times$ | $q^2$ | $1$ | $2q$ | $2q^2$ | $2q$ | $q^2 + 1$ |

Cohomologically non-trivial contributions are in the lower part of the table. The next transformations involve the $N - 1$ factor, which is inside the table: $(q + 1/q)[N - 1] \Longrightarrow (q + 1/q)[N - 2]$ is cohomologically equivalent to $(q + 1/q) \cdot q^{2-N} \Longrightarrow 0$, while $[N - 1](1 \Longrightarrow 2q \Longrightarrow q^2)$ - to $q^{2-N} \Longrightarrow q^{N-1} + q^{3-N} \Longrightarrow q^N$. This means that the next iteration is

| $[N - 1] \times$ | $q^N \times$ | $q^{-1}$ | $1$ |
|-------------------|---------------|-------|-----|
| $q^{-N} \times$ | $q^2 + 1$ | $2q + q^2 \left(q + \frac{1}{q}\right)$ | $2q^2 + q^2$ | $2q + q^3$ | $q^2 + 1$ |

and the second line is immediately reduced to

| $[N - 1] \times$ | $q^{-N} \times$ | $q^2$ | $q^3$ | $2q^2$ | $q$ | $q^3 + q$ | $q^2 + 1$ |
|-------------------|---------------|------|------|-------|----|-----------|--------|
| $q^N \times$ | $q^{-1}$ | $1$ |
| $q^{-N} \times$ | $1$ | $2q$ | $q^2$ |

Substituting once again

$$[N - 1](1 \Longrightarrow 2q \Longrightarrow q^2)$$

by

$q^{2-N} \Longrightarrow q^{N-1} + q^{3-N} \Longrightarrow q^N$

$$\frac{1}{q}[N - 1] \Longrightarrow [N - 1]$$

by

$q^{1-N} \longrightarrow q^{N-2}$

we obtain:

$$(qT)^2 P_{r_1}^{A_1} \sim q^{2-2N}(qT)^2 + \frac{q^N \times}{q^{-N} \times} q^{1-N} q^{N-2}$$

$$= q^{2-2N}(qT)^2 + q^{2-2N} + (q^{-1} + q^{3-2N}) (qT) + (qT)^2 + q \cdot (qT)^3 + q^{2N-2}(qT)^4$$

It remains to note that the two underlined items form a cohomologically trivial pair. Throwing it away, we finally obtain

$$P_{r_1}^{A_1} = \frac{1}{q^{2N}T^2} + \frac{1}{q^2 T} + 1 + q^2 T + q^{2N} T^2 = 1 + \left(q^{N+1}T^{3/2} + \frac{1}{q^{N+1}T^{3/2}}\right) \left(q^{N+1}T^{1/2} + \frac{1}{q^{N+1}T^{1/2}}\right)$$
The last expression is nothing but the superpolynomial $1 + \{Aq\}/\{A/t\}$ of [62, 73], expressed in our current notation.

In the case of unreduced polynomial we need to change the substitution rules (6.35), as usual: now we substitute

$$[N][N-1]\left(1 \rightarrow 2q \rightarrow q^2\right) \quad \text{by} \quad [N-1]\left(q^{1-N} \rightarrow q^N + q^{2-N} \rightarrow q^{N+1}\right)$$

$$\frac{1}{q}[N][N-1] \rightarrow [N][N-1] \quad \text{by} \quad [N-1](q^{-N} \rightarrow q^{N-1}) \quad (6.38)$$

The outcome acquires factors $[N-1]$ rather than $[N]$, and also the powers of $q$ are shifted by $\pm 1$. At the same time the item $q^{2-2N}$ in front of the table gets multiplied by $[N]$. This means that instead of (6.36) for unreduced polynomial we get

$$(qT)^2P^{41} \sim q^{2-2N}[N](qT)^2 + [N-1] \times \begin{array}{c|ccc}
q^N & q^{-N} & q^{N-1} \\
q^{-N} & q^{1-N} & q^N + q^{2-N} & q^{N+1}
\end{array} =$$

$$= q^{2-2N}[N](qT)^2 + [N-1]\left(q^{1-2N} + (1 + q^{2-2N})(qT) + q \cdot (qT)^2 + (qT)^3 + q^{2N-1}(qT)^4\right) \quad (6.39)$$

The two underlined terms $q^{2-2N}\left([N-1] \Rightarrow [N]\right)$ are cohomologically equivalent to $0 \Rightarrow q^{1-N}$, and $q^{1-N} + q[N-1] = [N]$, so that finally

$$P^{41} = [N] + [N-1]\left(\frac{1}{q^{2N+1}T^2} + \frac{1}{qT} + qT + q^{2N+1}T^2\right) \quad (6.40)$$

This is in accordance with [43].

### 6.3.8 Other initial vertices: three more representations for unknot

There are three other possible choices for initial vertex: $v_{21}$, $v_{10}$ and $v_{31}$ — all the three lead to unknot. If $v_{42}$ is taken for initial vertex, we get a "dual" representation of the trefoil with initial vertex $v_{00}$. It is instructive to briefly present these examples.

**Initial vertex $v_{21}$**

| $q^{2-2N}(qT)^2 + [N-1] \times$ | 1 | $(qT)$ | $(qT)^2$ | $(qT)^3$ | $(qT)^4$ |
|-----------------------------------|---|--------|--------|--------|--------|
| $v_{21}$                          | $2v_{10} + 2v_{31}$ | $v_{00} + 2v_{21} + 2v_{20} + 2v_{42}$ | $2v_{10} + 2v_{31}$ | $v_{21}$ |

| $[N-1]$ × | 4q + $\frac{2}{q}$ | $q^2 + 2 + 2(q^2 + 1) + 1$ | $4q + \frac{2}{q}$ | 1 |
| $[N-2]$ × | $q + \frac{1}{q}$ | $2q + 0 + 2(q^2 + 1) + 0$ | $2q$ | $→$ |

| $q^{-N}$ × | $2q$ | $2q^2 + 0 + 2(q^2 + 1) + 0$ | $2q$ | $→$ |

The first line with $[N-1]$ is cohomologically equivalent to

$$\begin{pmatrix}
0 & q + \frac{1}{q} & 0 & 0 & 0
\end{pmatrix}$$

it is combined with the second line to produce

$$\begin{pmatrix}
0 & q^{2-N} \left(q + \frac{1}{q}\right) & 0 & 0 & 0
\end{pmatrix}$$
what adds to the last line and gives:

\[
q^{2-2N}(qT)^2 + q^{-N}[N-1] \begin{pmatrix} 0 & 2q + q^2 \left(q + \frac{1}{q}\right) & 4q^2 + 2 & 2q & 0 \end{pmatrix} = \\
= q^{2-2N}(qT)^2 + q^{-N}[N-1] \begin{pmatrix} 0 & q & q^2 & 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & q^{3-2N} & 1 + q^{2-2N} & 0 & 0 \end{pmatrix} = 1
\]

(6.41)
as it should be for the unknot.

**Initial vertex \( v_{10} \)**

\[
q^{2-2N}(qT) + [N-1] \times 
\begin{array}{|c|c|c|c|c|c|}
\hline
1 & (qT) & (qT)^2 & (qT)^3 & (qT)^4 \\
\hline
v_{10} & v_{30} + v_{20} + 2v_{21} & 3v_{10} + 3v_{31} & v_{20} + 2v_{21} + v_{42} & v_{31} \\
\hline
[N-1] & q & q^2 + q^2 + 1 + 2 & 6q + \frac{4}{q} & q^2 + 1 + 2 + 1 & q + \frac{1}{q} \\
[N-2] & q & q^2 + q^2 + 1 & q & q^2 + 1 & \rightarrow \\
q^{-N} & q & \rightarrow & 2q^2 + q^2 + 1 & \rightarrow & 3q & \rightarrow & q^2 + 1 & \rightarrow \\
\hline
\end{array}
\]

The first line is cohomologically equivalent to \( q + \frac{1}{q} = [2] \) at the middle place, which is multiplied then by \([N-1]\) and further combined with \( q + \frac{1}{q} = [2] \) in the second line, multiplied by \([N-2]\). Cohomologically non-trivial remnant contributes \( q^{2-N} [2] \) to the middle place in the last line, converting it into

\[
\left( q \quad 3q^2 + 1 \quad q^2 [2] + 3q \quad q^2 + 1 \quad 0 \right)
\]

which is cohomologically trivial. Thus the KR polynomial is reduced to the single term \( q^{2-2N} \) outside the table. Since in this example original vertex is \( v_{10} \), i.e. has \( n_\bullet = 3 \) and \( n_o = 1 \), we finally get:

\[
\frac{q^{3N-3}}{q^{N+1}} \cdot q^{2-2N} (qT) = 1
\]

– exactly as needed for the unknot.

**Initial vertex \( v_{31} \)**

\[
q^{2-2N}(qT)^3 + [N-1] \times 
\begin{array}{|c|c|c|c|c|c|}
\hline
1 & (qT) & (qT)^2 & (qT)^3 & (qT)^4 \\
\hline
v_{31} & v_{20} + 2v_{21} + v_{42} & 3v_{10} + 3v_{31} & v_{20} + 2v_{21} + v_{42} & v_{31} \\
\hline
[N-1] & q + \frac{1}{q} & q^2 + 1 + 2 + 1 & 6q + \frac{4}{q} & q^2 + q^2 + 1 + 2 & q \\
[N-2] & q & q^2 + 1 & q & 2q^2 + q^2 + 1 & \rightarrow \\
q^{-N} & q & \rightarrow & q^2 + 1 & \rightarrow & 3q & \rightarrow & 2q^2 + q^2 + 1 & \rightarrow & q \\
\hline
\end{array}
\]

\[
= q^{2-2N}(qT)^3 + [N-1] \times 
\begin{array}{|c|c|c|c|c|c|}
\hline
1 & (qT) & (qT)^2 & (qT)^3 & (qT)^4 \\
\hline
[N-1] & q + \frac{1}{q} & 1 & 2q & q^2 \\
[N-2] & q + \frac{1}{q} & q + \frac{1}{q} & \rightarrow & 2q & \rightarrow & q^2 \\
q^{-N} & q & \rightarrow & 2q^2 + q^2 + 1 & \rightarrow & q \\
\hline
\end{array}
\]

32
\begin{align*}
= q^{2-2N}(qT)^3 + [N-1] \times \\
\begin{array}{|c|c|c|c|c|}
\hline
& 1 & (qT) & (qT)^2 & (qT)^3 & (qT)^4 \\
\hline
q^N & \times & q^{-N} & \times & \hline
q^{3-q} & \rightarrow & q^2 + 1 + q^2 & \rightarrow & q^{-1} & \rightarrow & 1 \\
\hline
\end{array}
\end{align*}

Underlined items in the last line came as cohomologically non-trivial remnant of the first two.
Together with the common factor \([N-1]\) the remaining table is cohomologically equivalent to

\begin{align*}
\begin{array}{|c|c|c|c|c|}
\hline
& 1 & (qT) & (qT)^2 & (qT)^3 & (qT)^4 \\
\hline
q^N & \times & q^{-N} & \times & \hline
1 & \rightarrow & q^{1-N} & \rightarrow & q^{N-2} & \rightarrow & q^N \\
\hline
\end{array}
\end{align*}

The underlined item combines in a cohomologically trivial pair with the term \(q^{2-2N}(qT)^3\) outside the table, and the answer for KR polynomial is made from the remaining last item. Since in this example \(n_\bullet = 1\) and \(n_\circ = 3\), the result is

\[
\frac{q^{N-1}}{(q^N T)^3} \cdot q^{2N-2}(qT)^3 = 1
\]

– as it should be for the unknot.

**Initial vertex \(v_{42}\)**

This is the same trefoil \([3, 2]\), but represented by "inverted" complex (6.42):

\[
v_{00} \xleftarrow{d_3} 4v_{10} \xleftarrow{d_2} 2v_{20} + 4v_{21} \xleftarrow{d_1} 4v_{31} \xleftarrow{d_0} v_{42}
\]

(6.42)

with absolutely different morphisms and differentials – they act in the opposite direction, but still decrease grading by one.

\[
q^{2-2N}(qT)^4 + [N-1] \times \\
\begin{array}{|c|c|c|c|c|}
\hline
& 1 & 4q + \frac{4}{q} & 2q^2 + 6 & 4q & q^2 \\
\hline
[N-1] \times & q + \frac{1}{q} & 2q + 2 & 4q & q^2 \\
\hline
[N-2] \times & q^{-N} \times & 2q^2 + 2 & 4q & 2q^2 \\
\hline
\end{array}
\]

(6.43)

This is the lengthiest example of all so far, because we need to handle "increasing" sequences may times.
First, eliminate all the "obvious" cohomologically trivial pieces – they are shifted to the upper part of the table:

\[
q^{2-2N}(qT)^4 + [N-1] \times \begin{array}{|c|ccc|}
\hline
[N-1] & 1 & \frac{1}{q} & 3 \\
[N-1] & \frac{2}{q} & q + \frac{1}{q} & 3 \\
[N-2] & q + \frac{1}{q} & 2q^2 \times 2q^2 \\
q^{-N} & 2q^2 + 2 & 4q & 2q^2 \\
\hline
\end{array}
\] (6.44)

In what follows we drop the upper part of the table.

In the lower part we have our familiar diagonal \((q+1/q)([N-2] \Rightarrow [N-1])\), but now it is in inverted order: the smaller space is embedded into the bigger one, and this is cohomologically equivalent to \((q+1/q)(0 \Rightarrow q^{N-2})\).

Increasing sequence in the first line

\[
\frac{2}{q} \Rightarrow 2 + 1 \Rightarrow q + q \Rightarrow q^2
\]

after multiplication by \([N-1]\) gets equivalent to

\[
\frac{2}{q}q^{2-N} \Rightarrow 2q^{N-2} + q^{2-N} \Rightarrow q \cdot q^{N-2} + q \cdot q^{N-2} \Rightarrow q^2 \cdot q^{N-2}
\]

Thus the lower part of above table is in fact equivalent to

\[
q^{2-2N}(qT)^4 + [N-1] \times \begin{array}{|c|ccc|}
\hline
q^N & 0 & q^{-2}(q + q^{-1}) & 2q^{-2} \\
q^{-N} & 0 & 2q & 3q^2 + q^3 \times 4q \times 2q^2 \\
\hline
\end{array}
\] (6.45)

where underlined items can be immediately eliminated to give

\[
q^{2-2N}(qT)^4 + [N-1] \times \begin{array}{|c|ccc|}
\hline
q^N & 0 & q^{-3} & q^{-2} \\
q^{-N} & 0 & 0 & q \times q^2 \\
\hline
\end{array}
\] (6.46)

The two increasing sequences, after multiplication by \([N-1]\), get equivalent to

\[
\begin{array}{|c|c|}
\hline
1 & q^{2-2N} \\
q^N & 0 \times q^{-3}q^{2-N} \times q^{-2}q^{N-2} \times q^{-1}q^{2-N} \times q^{N-2} \\
q^{-N} & 0 \times 0 \times q \times q \cdot q^{2-N} \times q^2q^{N-2} \\
\hline
\end{array}
\] (6.47)
where we also included the outside-the-table term with $q^{2-2N}$. After obvious reordering we get

$$
\begin{array}{ccc}
q^{2N} & \times & 0 \ 0 \ q^{-4} \ 0 \ q^{-2} \\
1 & \times & 0 \ q^{-1} \ 0 \ q \ 1 \\
q^{-2N} & \times & 0 \ 0 \ 0 \ q^3 \ q^2 \\
\end{array}
$$

The underlined terms form two cohomologically trivial pairs and the resulting KR polynomial contains just three terms:

$$
\frac{1}{(q^N T)^4} \left( q^{-1}(qT) + q^{2N-4}(qT)^2 + q^{2N-2}(qT)^4 \right) = q^{2-2N} \left( 1 + q^{-4}T^{-2} + q^{-2N-2}T^{-3} \right) = \mathcal{P}_r^{[3,2]}(q^{-1}, T^{-1}, N) \tag{6.48}
$$

where $\mathcal{P}_r^{[3,2]}$ is the KR polynomial for the trefoil, which we already reproduced in (5.42) and (6.27). As usual [1], reversion of complex means inversion of $q$ and $T$ in the answer.

For unreduced KR polynomial the difference appears in the transition from (6.46), multiplied by a common $[N]$, to (6.47): we should now use $[N]$ instead of $[N - 1]$ in eliminating the cohomologically trivial pieces and get instead of (6.47):

$$
q^{2-2N}(qT)^4[N] + [N - 1] \times
\begin{array}{ccc}
q^N & \times & 0 \ q^{-3}q^{1-N} \ q^{-2}q^{N-1} \ q^{-1}q^{1-N} \ q^{N-1} \\
q^{-N} & \times & 0 \ 0 \ 0 \ q \ q^{1-N} \ q^2q^{N-1} \\
\end{array}
$$

or, after reordering:

$$
q^{2-2N}(qT)^4[N] + [N - 1] \times
\begin{array}{ccc}
q^{2N} & \times & 0 \ 0 \ q^{-3} \ 0 \ q^{-1} \\
1 & \times & 0 \ q^{-2} \ 0 \ 1 \ q \\
q^{-2N} & \times & 0 \ 0 \ 0 \ q^2 \ 0 \\
\end{array}
$$

Underlined are the terms, which were cohomologically trivial in reduced case. Now things are a little more difficult. For single-underlined terms we substitute $[N - 1](1 \Rightarrow q)$ by $(q^{2N} \Rightarrow q^{N-1})$, for doubled-underlines terms we substitute $(q^{2-2N}[N - 1] \Rightarrow q^{2-2N}[N])$ by $(0 \Rightarrow q^{2-2N}q^{N-1}) = (0 \Rightarrow q^{1-N})$. The two underlined terms in these new contributions form a cohomologically trivial pair, which can be eliminated. After that the KR polynomial becomes

$$
\frac{1}{q^{4N T^4}} \left\{ ([N - 1]\left( (q^{-2}(qT) + q^{2N-3}(qT)^2 + q^{2N-1}(qT)^4 \right) \right) + q^{N-1}(qT)^4 \right\} = q^{2-2N} \left\{ [N] + q^{-3}T^{-2}[N - 1] + q^{-2N-3}T^{-3}[N - 1] \right\} = \mathcal{P}_r^{[3,2]}(q^{-1}, T^{-1}, N) \tag{6.49}
$$

i.e. is appropriately related to (6.28) and (5.42).

### 6.3.9 The 3-component 3-braid torus link $[3, 3]$ ($6_3^2(v1)$ of [43])

The braid diagrams for the 3-strand links can be represented as two strings of black or white dots, standing at positions of the $R$-matrices $R_1^{\pm 1}$ and $R_2^{\pm 1}$ - without drawing the strands themselves (what simplifies the drawing a lot). If restored, the strands would go from the left to the right. In the particular case of the torus link $[3, 3]$ this picture looks as follows:

```
• • • • •
```
or, with the strands restored:

The KR complex in this case consists of the space with dimensions

\[
\begin{align*}
\dim_0 &= v_{0,0} = [N]^2 \\
\dim_1 &= 6v_{1,0} = 6[N][N-1] \\
\dim_2 &= 6v_{2,0} + 9v_{2,1} = 6[2][N][N-1] + 9[N-1]^2 \\
\dim_3 &= 2v_{3,0} + 18v_{3,1} = 2[2]^2[N][N-1] + 18[N-1]^2[2] \\
\dim_4 &= 9v_{4,1} + 6v_{4,2} = 9[2]^2[N-1]^2 + 6[N-1]^2 + 6[2][N-1][N-2] \\
\dim_5 &= 6v_{5,2} = 6[2][N-1]^2 + 6[2]^2[N-1][N-2] \\
\dim_6 &= v_{6,3} = [N-1]^2 + ([2] + [2]^3)[N-1][N-2]
\end{align*}
\]

From this we read:
To reproduce the answer from [43], the term \( q^3 \implies q^2 \) should be preserved in the last line – but only once, its second copy is sent to the cohomologically trivial part. Now, restoring the factor \([N - 1]\) and making use of (6.25), we obtain for the KR polynomials:

\[
\mathcal{P}^{[3,3]}_r = q^{6N-6} \left( q^{2-2N} + q^{1} + q^{2-2N} (qT)^2 + q (qT)^3 + (q^{2-2N} + 2q^{1}) [N - 1] (qT)^4 + q^3 [N - 1][N - 2] (qT)^5 \right)
\]

\[
= q^{4N-4} \left( 1 + q^4 T^2 + q^{2N+2} T^3 + (q^{N+4} + 2q^{N+6}) [N - 1] T^4 + q^{2N+7} [N - 1][N - 2] T^6 \right)
\]

Similarly, using (??),

\[
\mathcal{P}^{[3,3]} = q^{4N-4} \left( [N] + q^3 [N - 1] T^2 + q^{2N+3} [N - 1] T^3 + (q^{N+4} + 2q^{N+6}) [N] [N - 1] T^4 + q^{2N+7} [N - 1][N - 2] T^6 \right)
\]
This reproduces the two answers, obtained for $6_3^3(v1)$ in [43] for $N = 2$ and $N = 3$:

### Reduced Case

$$N = 2 : \quad q^4 \left( 1 + q^4 T^2 + q^6 T^3 + (q^6 + 2q^8)T^4 \right)$$

$$N = 3 : \quad q^8 \left( 1 + q^4 T^2 + q^8 T^3 + (q^6 + 3q^8 + 2q^{10})T^4 + (q^{12} + q^{14})T^6 \right) \quad (6.51)$$

### Unreduced Case

$$N = 2 : \quad q^4 \left( 2 + q^3 T^2 + q^7 T^3 + (q^6 + 2q^8)[2]T^4 \right)$$

$$N = 3 : \quad q^8 \left( 3 + (q^2 + q^4)T^2 + (q^8 + q^{10})T^3 + (q^6 + 3q^8 + 2q^{10})[3]T^4 + (q^{12} + q^{14})[3]T^6 \right) \quad (6.52)$$

Relation of Unreduced Polynomial to the Superpolynomial from eq.(148) of [56]

$$\frac{1}{(1 - q^2)^2} \left( (1 - 2q^2 + q^4) + (q^4 - 2q^6 + q^8)T^2 + (q^2 - 2q^4 + q^6)T^3a^2 + (q^6 + q^8 + 2q^{10})T^4 + (q^4 + q^6 - 2q^8)T^5a^2 + q^{12}T^6 + q^9[2]T^7a^2 + q^6T^8a^4 \right) =$$

$$= 1 + q^4T^2 + q^2T^3a^2 + q^4(1 + 2q^2)T^4 \frac{q^2 + a^2T}{1 - q^2} + q^6T^6 \frac{(q^2 + a^2T)(q^4 + a^2T)}{(1 - q^2)^2} \quad (6.53)$$

is somewhat more involved. To obtain a superpolynomial, which is a function of $q$ instead of $N$ one should substitute $a = q^N$ instead of powers $q^N$ in (??), while quantum numbers are substituted by

$$[N - 1] \rightarrow \frac{q^2 + Ta^2}{a(1 - q^2)},$$

$$[N - 2] \rightarrow \frac{q^4 + Ta^2}{aq(1 - q^2)} \quad (6.54)$$

- this is instead of the naive $\frac{q^{N-1} - q^{-N}}{q - q^{-1}} = \frac{q^N - q^{-N}}{q^N - q^{-N}} = \frac{q^N - q^{-N}}{aq(1 - q^2)}$, which would not provide a positive polynomial in $a$. The same rule applies to unreduced polynomials (for knots the reduced KR polynomials do not contain quantum numbers). Note that these substitutions increase the full degree of the polynomial in $T$. Some comments on this issue can be found in [50] and [56].

### 6.3.10 Another Coloring: the 3-component Borromean link ($L6a4$ of [79] or $6_2^3$ of [43])

If instead of $R_1R_2R_1R_2$ we consider $R_1^{-1}R_1^{-1}R_2^{-1}R_1^{-1}R_2^{-1}$, then the braid is

- \[ \begin{array}{cccccc}
    \bullet & \bullet & \bullet & \circ & \circ & \circ \\
\end{array} \]

The positions of points (and thus the hypercube) are the same, but the colorings (and thus morphisms and the KR complex) are different. Actually, the KR complex

$$v_{00} \rightarrow d_0 \rightarrow 6v_{10} \rightarrow d_1 \rightarrow 6v_{20} + 9v_{21} \rightarrow d_2 \rightarrow 2v_{30} + 18v_{31} \rightarrow d_3 \rightarrow 9v_{41} + 6v_{42} \rightarrow d_4 \rightarrow 6v_{52} \rightarrow d_5 \rightarrow v_{63} \quad (6.55)$$

is changed for

$$v_{30} \rightarrow d_0 \rightarrow 3v_{20} + 3v_{41} \rightarrow d_1 \rightarrow 3v_{10} + 9v_{31} + 3v_{52} \rightarrow d_2 \rightarrow v_{00} + 9v_{21} + 3v_{41} + 6v_{42} + v_{63} \rightarrow d_3 \rightarrow 3v_{10} + 9v_{31} + 3v_{52} \rightarrow d_4 \rightarrow 3v_{20} + 3v_{41} \rightarrow d_5 \rightarrow v_{30} \quad (6.56)$$
and therefore
\[
\left( \frac{q^{3N-3}}{q^{4N} T^3} \right)^{-1} \cdot q^{63} = q^{2-2N} \cdot (qT)^3 + [N - 1] \times
\]

| $[N - 1] \times$ | $q[2]^2$ | $3q[2] + 3[2]^2$ | $3q + 9[2] + 3[2]$ | $q^2 + 9 + 3[2]^2 + 6 + 1$ | $3q + 9[2] + 3[2]$ | $3q[2] + 3[2]^2$ | $q[2]^2$ |
|-----------------|---------|------------------|------------------|----------------|----------------|----------------|--------|
| $[N - 2] \times$ | $3[2]^2$ | $6[2] + 2(1 + [2]^2)$ | $3[2]^2$ | $q^{-N} \times$ | $q[2]^2$ | $3q$ | $2q^2$ | $3q$ | $3q[2]$ | $q[2]^2$ |

In more detail the table is:

| $[N - 1] \times$ | $q^3$ | $3q^2$ | $q^{-1}$ | $q^{-N} \times$ | $q^3$ | $3q^2$ |
|-----------------|-------|--------|----------|----------------|------|-------|
| $[N - 1] \times$ | $6q^2$ | $2q$ | $q^{-1}$ | $q^3$ | $3q^2$ | (1) |
| $[N - 1] \times$ | $4q^2$ | $15q$ | $9$ | $2q$ | $9$ | $3q^2$ | $3q^{-2}$ | (2) |
| $[N - 1] \times$ | $q^3$ | $6q^2$ | $15q$ | $22 \cdot 1$ | $12q^{-1}$ | $3q^{-2}$ | (3) |
| $[N - 1] \times$ | $2q$ | $9$ | $12q^{-1}$ | $3q^{-2}$ | (2) |
| $[N - 1] \times$ | $q^{-1}$ | $3q^{-2}$ | $q^{-3}$ | (2) |
| $[N - 2] \times$ | $q^3$ | $3q^2$ | $q^{-1}$ | $q^{-N} \times$ | $q^3$ | $3q^2$ |
| $[N - 2] \times$ | $3q^2$ | $10q$ | $6$ | $2q^2$ | $3q$ | $q^{-1}$ | (1) |
| $[N - 2] \times$ | $6$ | $10q^{-1}$ | $3q^{-2}$ | (1) |
| $[N - 2] \times$ | $3q^{-2}$ | $q^{-3}$ | (2) |

$q^{2-2N} + (qT)^{-3} [N - 1] \times$
The cohomologically non-trivial part is restricted by the values of alternated sums in lines and at the next step reduces to

\[ q^{2-2N} + (qT)^{-3}[N-1] \times \]

\[
\begin{array}{c|ccccccc}
[N-1] \times & 0 & 2q^{-2} & 2q^{-1} & 3 & 3q & 4q^2 & q^3 \\
[N-2] \times & 0 & 0 & 2q^{-2} & q^{-1} + q & 2q^2 \\
q^{-N} \times & q^{-1} & 1 & q & q^2 & 0 & q^2 & q^3 \\
\end{array}
\]

\[ \sim q^{2-2N} + (qT)^{-3}[N-1] \times \]

\[
\begin{array}{c|ccccccc}
[N-1] \times & & & & 1 \\
q^N \times & q^{-1} & 2 & 0 \\
q^N \times & 0 & 0 & 0 & q^{-2} & q^{-1} & 1 & q \\
q^{-N} \times & 0 & 0 & q & q^2 & q^3 & q^4 & 0 \\
q^{-N} \times & 0 & 2 & q & & & & \\
q^{-N} \times & q^{-1} & 1 & q & q^2 & 0 & q^2 & q^3 \\
\end{array}
\]

\[ \sim [N-1]^2 + (q^{N-2} + q^{2-N})[N-1] + (qT)^{-3}[N-1] \times \]

\[
\begin{array}{c|c}
q^N \times & 2q^{-1} & 3 & q \\
q^{-N} \times & q^{-1} & 3 & 2q \\
q^{-N} \times & q & q^2 \\
\end{array}
\]

\[ \sim [N-1]^2 + (q^{N-2} + q^{2-N})[N-1] + (qT)^{-3} \times \]

\[
\begin{array}{c|c}
q^{2N} \times & 2q^{-2} & q^{-1} \\
1 \times & 2q & q^2 \\
1 \times & q^{-2} & 2q^{-1} \\
q^{-2N} \times & q & 2q^2 \\
1 \times & 1 \\
q^{-2N} \times & q^3 & q^2 \\
\end{array}
\]

The underlined term, standing after the next-to-the-last table is absorbed into the last table, where it is eliminated together with another underlined term in the last line.

Thus reduced KR polynomial is

\[
P_{r}^{63} = \frac{1}{q^{2N+2T^3}} + \frac{q^{N-2} + 2q^{2-N}}{q^{N+2T^2}} + \frac{2}{q^2T} + \\
\left( [N-1] + q^{N-2} \right) \left( [N-1] + q^{2-N} \right) + 2q^2T + (2q^{N-2} + q^{2-N}) \cdot q^{N+2T^2} + q^{2N+2T^3} \\
\]

(6.57)
In unreduced case the deviation begins from the next-to-the-last table:

\[
\mathcal{P}^6_2 \sim [N][N-1]^2 + (q^{N-2} + q^{2-N})[N][N-1] + (qT)^{-3}[N][N-1] \times \begin{array}{ccc}
q^N \times & q^N \times & 2q^{-1} 3 q \\
q^{-N} \times & q^{-N} \times & 2q \\
q^{-N} \times & q^{-N} \times & q \end{array} + \frac{q^{2-2N}[N]}{q^{1-2N}[N-1]+q^{-N}}
\]

\[
\sim [N][N-1]^2 + (q^{N-2} + q^{2-N})[N][N-1] + q^{1-N} + (qT)^{-3}[N-1] \times \begin{array}{ccc}
q^{2N} \times & 2q^{-1} & 1 \\
1 \times & q^{-1} & 2 \\
q^{-2N} \times & 1 & 2q \\
1 \times & q & 0 \\
q^{-2N} \times & q^2 & q
\end{array}
\]

and, absorbing \(q^{1-N}\) back into \(q^{1-N} + q[N-1] = [N]\), we obtain unreduced polynomial:

\[
\mathcal{P}^6_2 = \left(1 + \frac{q^{N-1} + 2q^{1-N}}{q^{N+2T^2}} + \frac{2}{qT}\right)[N-1] + \left(\frac{2}{qT} + \frac{1}{q^3T^2}\right)[N-1] + \left(\frac{2}{qT} + \frac{1}{q^3T^2}\right)[N-1] + \left(\frac{2}{qT} + \frac{1}{q^3T^2}\right)[N-1] + \left(\frac{2}{qT} + \frac{1}{q^3T^2}\right)[N-1] = (6.58)
\]

Both (6.57) and (6.58) are in agreement with the results if [43] for \(N = 2, 3, 4\) and \(N = 2, 3\) respectively.

For \(T = -1\) these expressions reduce to

\[
H_r^3 = [N]^2 - \left(q - \frac{1}{q}\right)^4 \cdot [N+1][N-1], \quad H_t^3 = [N] \cdot H_r^3
\]

known from [75] (where also generalizations of Borromean HOMFLY to arbitrary triples of symmetric representations was found).

6.3.11 Still another coloring: the 3-component link 6^3_5(v2) of [43])

If instead of \(R_1R_2R_1R_2\) we consider \(R_1R_2^{-1}R_1R_2^{-1}R_2\), then the braid becomes

\[
\bullet \quad \circ \quad \bullet \quad \circ \quad \bullet
\]

(6.60)

and the KR complex

\[
v_{00} \xrightarrow{d_0} 6v_{10} \xrightarrow{d_1} 6v_{20} + 9v_{21} \xrightarrow{d_2} 2v_{30} + 18v_{31} \xrightarrow{d_3} 9v_{41} + 6v_{42} \xrightarrow{d_4} 6v_{52} \xrightarrow{d_5} v_{63}
\]

(6.61)

is changed for

\[
v_{21} \xrightarrow{d_0} 2v_{10} + 4v_{31} \xrightarrow{d_1} v_{00} + 4v_{20} + 4v_{21} + v_{41} \xrightarrow{d_2} 4v_{10} + 2v_{30} + 10v_{31} + 4v_{52} \xrightarrow{d_3} 2v_{20} + 4v_{21} + 4v_{41} + 4v_{42} + v_{63} \xrightarrow{d_4} 4v_{31} + 2v_{52} \xrightarrow{d_5} v_{41}
\]

(6.62)
Note that the right endpoint of the complex is \( v_{41} \) rather than \( v_{42} \) – this is the property of the coloring (6.60).

The primary polynomial, associated with this complex, is

\[
\left( \frac{q^{4N-4}}{q^{2N} T^2} \right)^{-1} \Psi_{r}^{63(v2)} = q^{2-2N} \cdot (qT)^2 + [N - 1] \times
\]

\[
\begin{array}{cccccccccc}
[N - 1] \times & 1 & 2q + 4[2] & q^2 + 4q[2] + 4 + 4[2]^2 + 2 & 4q + 2q[2]^2 + 10[2] + 4[2] & 2q[2] + 4 + 4[2]^2 + 4 + 1 & 4[2] + 2[2] & [2]^2 \\
[N - 2] \times & 0 & 0 & 2[2] & 4[2]^2 & 4[2] + [2](1 + [2]^2) & 2[2]^2 & 0 \\
q^{-N} \times & 0 & 2q & 2q^2 + 4q[2] & 4q + 2q[2]^2 & 2q[2] & 0 & 0
\end{array}
\]

The table can be rewritten as

\[
\begin{array}{cccccccc}
[N - 1] \times & 0 & 2q & 6q^2 + 4 & 2q^3 + 8q + \frac{2}{q} & 2q^2 + 2 & 0 & 0 \\
\end{array}
\]

If we pick up only the five underlined terms – the minimum allowed by Euler characteristics in lines – then the table reduces to

\[
\begin{array}{cccccccc}
[N - 1] \times & 0 & 0 & \frac{1}{q} & 0 & 1 & 0 & q^2 \\
[N - 2] \times & 0 & 0 & \frac{1}{q^2} & 0 & 1 & 0 & q^2
\end{array}
\]

\[
\equiv 0 \quad 0 \quad q^{-N} \quad 0 \quad [N - 1] \quad 0 \quad q^N \quad (6.63)
\]

what would give rise to a very compact polynomial

\[
\Psi_{r}^{63(v2)} \equiv 1 + q^{-2N} [N - 1] + q^{2N} [N - 1]^2 T^2 + q^{3N+2} [N - 1] T^4 \quad (6.64)
\]

Unfortunately this is not the right answer – it does not match the results of [43]. The real reason for this would come from analysis of morphisms – which we postpone to a separate publication. However, this failure is easy to expect, because formula (6.64) has two apparent irregularities: instead of the typical factor \([N - 1][N - 2]\) for 3-component links we got \([N - 1]^2\), and the third term in the complex which normally has simple, but non-trivial cohomology, vanishes.
The right answer arises if we keep three seemingly trivial pairs in (6.65), coming from the lines with vanishing Euler characteristics:

$$q^{2-2N} + [N - 1] \cdot$$

| $[N - 1] \times$ | 0 | 0 | $\frac{1}{q^2} + 1$ | $\frac{1}{q}$ | 1 | 0 | $q^2$ |
|------------------|---|---|------------------|---------|---|---|---|
| $[N - 2] \times$ | 0 | 0 | $\frac{1}{q^2} + 1 + q^2$ | $\frac{1}{q}$ | | $q^2$ | 0 |

$$q^{2-2N} + [N - 1] :$$

| 0 | 0 | $q^{-N} + q^{2-N}$ | $q^{1-N}$ | $q^{-2N} + [N - 2]$ | 0 | $q^N$ |

(6.65)

It remains to substitute the two underlined terms $[N - 1](q^{1-N} \Rightarrow q^{2-N})$ by $q^{3-2N} \Rightarrow q^{N-2} \cdot q^{2-N} = 1$ in reduced case and $[N - 1][N](q^{1-N} \Rightarrow q^{2-N})$ by $[N - 1](q^{3-2N} \Rightarrow q^{N-1} \cdot q^{2-N} = q)$ in unreduced case. This provides the right reduced and unreduced polynomials:

$$P_r^{63}(v^2) = q^{2N-2}(qT)^2 \left\{ (q^{2-2N} + (q^2 + 1)q^{-N}[N - 1])(qT)^2 + q^{3-2N}(qT)^3 + \left(1 + q[N - 1][N - 2]\right)(qT)^4 + q^N[N - 1](qT)^6 \right\} =$$

$$= 1 + q^{N-1}[2][N - 1] + q^2T + \left(q^{2N} + q^{N+1}[N - 1][N - 2]\right)T^2 + q^{3N+2}[N - 1]T^4,$$

$$P_r^{63}(v^2) = [N + q^{N-1}[2][N - 1] + q[N - 1]T + q^{2N+1}[N - 1]\left(1 + [N][N - 2]\right)T^2 + q^{3N+2}[N]N - 1)T^4$$

For $N = 2, 3$ this reproduces the answers from [43] in reduced case

$$N = 2 : \quad 2 + 2q + q^2T + q^4T^2 + q^8T^4$$

$$N = 3 : \quad 2 + 2q^2 + q^4T + (q^4 + 3q^6 + 3q^8 + q^{10})T^2 + (q^8 + 2q^{10} + 2q^{12} + q^{14})T^4$$

(6.67)

and in unreduced case

$$N = 2 : \quad 2 \frac{2}{q} + 3q + q^3T + q^5T^2 + (q^7 + q^9)T^4$$

$$N = 3 : \quad 2 \frac{2}{q} + 4 + 5q^2 + 3q^4 + q^6 + (1 + q^2)T + (q^4 + 3q^6 + 3q^8 + q^{10})T^2 + (q^8 + 2q^{10} + 2q^{12} + q^{14})T^4$$

(6.68)

### 6.3.12 The knot $[3, 4]$ (also known as $8_{19}$)

$$\dim_0 = v_{0,0} = [N]^2$$

$$\dim_1 = 8v_{1,0} = 8[N][N - 1]$$

$$\dim_2 = 12v_{2,0} + 16v_{2,1} = 12[2][N][N - 1] + 16[N - 1]^2$$

$$\dim_3 = 8v_{3,0} + 48v_{3,1} = 8[2][N][N - 1] + 48[2][N - 1]^2$$

$$\dim_4 = 2v_{4,0} + 48v_{4,1} + 20v_{4,2} = 2[2][N][N - 1] + 48[2][N - 1]^2 + 20[N - 1]^2 + 20[2][N - 1][N - 2]$$

$$\dim_5 = 16v_{5,1} + 40v_{5,2} = 16[2][N - 1]^2 + 40[2][N - 1]^2 + 40[2][N - 1][N - 2]$$

$$\dim_6 = 20v_{6,2} + 8v_{6,3} = 20[2][N - 1]^2 + 20[2][N - 1][N - 2] + 8[N - 1]^2 +$$

$$+ 8([2] + [2]^3)[N - 1][N - 2]$$

$$\dim_7 = 8v_{7,3} = 8[2][N - 1]^2 + 8([2]^2 + [2]^4)[N - 1][N - 2]$$

$$\dim_8 = v_{8,4} = [N - 1]^2 + ([2] + [2]^3 + [2]^5)[N - 1][N - 2]$$
\[ q^{8-8N} p_r^{[3,4]} = q^{2-2N} + [N - 1] \times \]

| \([N - 2]\) | \(|N - 1\) | \(q^5\) |
|---|---|---|
| \(q\) | \(8q^4\) | \(6q^3\) |
| \(q^2\) | \(16q^3\) | \(20q^2\) | \(q^4\) | \(8q\) | \(1\) |
| \(q^3\) | \(54q^2\) | \(88q\) | \(48\) | \(q^5\) | \(8q\) | \(14q\) |
| \(q^4\) | \(72q\) | \(96q\) | \(64\) | \(q^6\) | \(14\) |
| \(q^5\) | \(96q^2\) | \(128q\) | \(256\) | \(q^7\) | \(6\) |
| \(q^6\) | \(12q^2\) | \(64q\) | \(142\) | \(q^8\) | \(20q\) |
| \(q^7\) | \(20q^2\) | \(80\) | \(q^9\) | \(q^2\) |
| \(q^8\) | \(2q^2\) | \(8q\) | \(28\) | \(q^4\) |
| \(q^9\) | \(12q^2\) | \(16q\) | \(6\) |
| \(q^{10}\) | \(8q^3\) | \(6q^2\) |
| \(q^{11}\) | \(2q^4\) |

(6.69)
The first three lines are transformed as follows:

\[
q^3[N - 1][N - 2] \implies q^4[N - 1][N - 2] \implies q^5[N - 1][N - 2]
\]  

(6.70)

\[
q^{8-2N} \implies [2]q^4 \implies q^{2N}
\]

and the last seven lines – as

\[
q^{-N}[N - 1] \times
\]

\[
\begin{array}{cccc}
2q^2 & q & 2q^2 & 2q^2 \\
2q^3 & q^3 & 2q^3 & q^5 \\
q^2 & q^3 & [2]q^3 & [2]q^4
\end{array}
\]

(6.71)

If we made the maximal possible cancelations inside this table, only two terms would remain, \(q^2\) and \(q^5\), but separated by a gap – and the full contribution to the KR polynomial would be \(\sim q^{-N}[N - 1]\left(q^2(qT)^2 + q^5(qT)^5\right)\) i.e. proportional to \(N - 1\). Keeping more terms inside the table makes the full contribution much smaller:

\[
q^{-N} \times q^2[N - 1] \quad q^3[N - 1] \\
[2]q^{-N} \times q^3[N - 1] \quad q^4[N - 1]
\]

(6.72)

\[
q^{-N} \times q^4-N \quad q^{N+1} \\
[2]q^{-N} \times q^5-N \quad q^{N+2}
\]

leads to \(\sim q^{-N}\left(q^{4-N}(qT)^2 + q^{N+1}(qT)^3 + [2]q^{5-N}(qT)^4 + [2]q^{N+2}(qT)^5\right)\). Of course, at \(T = -1\) this coincides with \(q^{-N}[N - 1]\left(q^2(qT)^2 + q^5(qT)^5\right)\).

Collecting all the contributions, we obtain:

\[
P^{[3,4]}_T = q^{8N-8}\left\{q^{2-2N} + q^{4-2N}(qT)^2 + q^5(qT)^3 + [2]q^{5-2N}(qT)^4 + [2]q^2(qT)^5 + q^{8-2N}(qT)^6 + [2]q^4(qT)^7 + q^2N(qT)^8\right\}
\]

(6.73)

\[
= q^{6N-6}\left\{1 + q^4T^2 + q^{2N+2}T^3 + [2]q^7T^4 + [2]q^{2N+5}T^5 + q^{12}T^6 + [2]q^{2N+9}T^7 + q^{4N+6}T^8\right\}
\]

what is in perfect agreement with [50] and [56]:

\[
1 + q^4T^2 + a^2q^2T^3 + [2]q^7T^4 + [2]q^5T^5a^2 + q^{12}T^6 + [2]q^9T^7a^2 + q^6T^8a^4
\]

(6.74)

In unreduced case we need appropriate modification of (6.70) and (6.72):

\[
q^3[N][N - 1][N - 2] \implies q^4[N][N - 1][N - 2] \implies q^5[N][N - 1][N - 2]
\]  

(6.75)

\[
q^{6-2N}[N - 2] \implies [2]q^4[N - 2] \implies q^{2N+2}[N - 2]
\]
and

\[
\begin{array}{cccc}
q^{-N} & q^2[N][N - 1] & q^3[N][N - 1] \\
[2]q^{-N} & q^3[N][N - 1] & q^4[N][N - 1]
\end{array}
\]  

(6.76)

\[
\begin{array}{cccc}
q^{-N} & q^{3-N}[N - 1] & q^{N+2}[N - 1] \\
[2]q^{-N} & q^{4-N}[N - 1] & q^{N+3}[N - 1]
\end{array}
\]

The latter is already familiar from the previous examples, the former is new.

With the help of these relations we get:

\[
q^{8N-8}\left\{q^{2-2N}[N] + q^{3-2N}[N - 1](qT)^2 + q^2[N - 1](qT)^3 + [2]q^{4-2N}[N - 1](qT)^4 + [2]q^3[N - 1](qT)^5 + \\
+q^{6-2N}[N - 2](qT)^6 + [2]q^4[N - 2](qT)^7 + q^{2N+2}[N - 2](qT)^8\right\} = \\
= q^{6N-6}\left\{[N] + q^3[N - 1]T^2 + q^{2N+3}[N - 1]T^3 + [2]q^6[N - 1]T^4 + [2]q^{2N+6}[N - 1]T^5 + \\
+q^{10}[N - 2]T^6 + [2]q^{2N+9}[N - 2]T^7 + q^{4N+8}[N - 2]T^8\right\}
\]

(6.77)

There is nothing to compare this formula with. Unreduced superpolynomials for torus knots and links are *not* provided by the evolution method of [56, 73] and its relatives of [55, 57]. One the other hand, the knot [3, 4] has 8 crossings, and as such it remained beyond reach of the matrix-factorization calculations in [43]. In the absence of both known results and explicitly constructed morphisms, we need to rely upon other mind of arguments. As we shall see in s.8 below it is most plausible that (6.77) is *overduced* – all known answers imply that unreduced KR polynomials for 3-strand knots should contain only \([N - 1]\) factors, not \([N - 2]\). Accordingly, we find more eq.(8.28) from sec.8 to be more plausible than (6.77).

6.3.13 General case

We omit the powers of \(q\) because they depend in a clear way on position in the table. Horizontal lines are inserted to simplify reading the table.
If the structure is not fully clear at this level, here are the next three columns of the table:
\begin{align*}
\sum_{m=1}^{2n} (-)^m s_{m,0} &= 0, \\
\sum_{m=2k}^{2n} (-)^m s_{m,k} &= \delta_{k,n}, \quad k > 0
\end{align*}

We remind that $s_{m,k}$ is non-vanishing when $m \leq n + k$ and $k \leq \frac{n}{2}$ and therefore $m \leq 2n$. Alternate sums are linear combinations of the identities like

\begin{align*}
2 + \sum_{m=1}^{2n} (-)^m s_{m,0} &= 0, \\
\sum_{m=2k}^{2n} (-)^m s_{m,k} &= \delta_{k,n}, \quad k > 0
\end{align*}
Then, for example, in the lowest non-trivial line we have
\[
s_{42} - s_{52} + (s_{62} + s_{63}) - (s_{72} + s_{73}) + (s_{82} + s_{83} + s_{84}) - \ldots =
\]
\[
= (s_{42} - s_{52} + s_{62} - s_{72} + s_{82} - \ldots) + (s_{63} - s_{73} + s_{83} - \ldots) + (s_{84} - \ldots) + \ldots =
\]
\[
= \delta_{n2} + \delta_{n3} + \delta_{n4} + \ldots = 1 - \delta_{n1} = \delta_{n>1}
\] (6.79)

In general alternated sums in the lines with \([N - 1]\) are evaluated with the help of the formulas
\[
\sum_{m=p}^{2n} (-)^{m+p} \frac{(m-1)!}{(p-1)!(m-p)!} s_{m0} + \sum_{k=1}^{p} \left( \sum_{m=p+k}^{2n} (-)^{m+p} \frac{(m-2k)!}{(p-k)!(m-p-k)!} s_{m,k} \right) = 2\delta_{n>p} + \gamma_p \delta_{n,p}
\] (6.80)

where the deviation \(\gamma_p\) is periodic in \(p\), \(\gamma_{p+6} = \gamma_p\), and
\[
\gamma_1 = 1, \quad \gamma_2 = -1, \quad \gamma_3 = -2, \quad \gamma_4 = -1, \quad \gamma_5 = +1, \quad \gamma_6 = +2, \quad \gamma_7 = +1, \ldots
\] (6.81)

Similar periodicity occurs in the lines with \([N - 2]\): the alternated sums are equal to
\[
\beta_p \delta_{n>p}
\] (6.82)

with \(\beta_{p+6} = \beta_p\)
\[
\beta_1 = -1, \quad \beta_2 = -2, \quad \beta_3 = -2, \quad \beta_4 = -1, \quad \beta_5 = 0, \quad \beta_6 = 0, \ldots
\] (6.83)

(in the two lowest line we actually write \(\gamma_1 \delta_{n>1}\) and \(-\beta_1 \delta_{n>1}\), because they begins from a ”wrong” place). Here are a few more Euler characteristics in the \([N - 2]\)-lines are:
\[
\ldots (-\delta_{n>16} + 2\delta_{n,16} + \delta_{n,15} + 2\delta_{n,13} + \delta_{n,12} + 2\delta_{n,10} + \delta_{n,9})
\]
\[
\ldots (-2\delta_{n>15} + 2\delta_{n,15} + \delta_{n,13} + 2\delta_{n,12} + \delta_{n,10} + 2\delta_{n,9})
\]
\[
\ldots (-2\delta_{n>14} + \delta_{n,14} + 2\delta_{n,12} + \delta_{n,11} + 2\delta_{n,9} + \delta_{n,8})
\]
\[
\ldots (-\delta_{n>13} + \delta_{n,12} + 2\delta_{n,11} + \delta_{n,9} + 2\delta_{n,8})
\]
\[
\ldots (2\delta_{n,11} + \delta_{n,10} + 2\delta_{n,8} + \delta_{n,7})
\]
\[
\ldots (\delta_{n,11} + 2\delta_{n,10} + \delta_{n,8} + 2\delta_{n,7})
\] (6.84)

Their structure and values for arbitrary \(n\) and \(p\) is fully clear from these expressions.

6.3.14  The knot \([3, 5]\)

Before proceeding generically we analyze two more examples – already with the help of this general table – to better see, how things work. For the case \(n = 5\) the table becomes:
As usual we begin with the adjacent lines, multiplied by \([N - 1]\) and \([N - 2]\). From above table it is already clear, that a reordering takes place in the middle – at the central cross, and adjacent items are naturally grouped in pairs along differently directed diagonals. Accordingly we need three kinds of substitutions:

\[
[N - 1] \implies [N - 2] \quad \text{by} \quad q^{2-N} \implies 0 \quad (6.86)
\]

\[
q^2[N - 1] \implies q^1[N - 2] \quad \text{by} \quad q^{6-N} + q^{4-N} \implies q^{N+1}
\]

and

\[
[N - 2] \implies q[N - 2] \quad \text{by} \quad q^{3-N} \implies q^{N-2}
\]

in the left lower corner, the central cross and the right upper corner respectively. The underlined item 2\(q^2\) is split into two \(q^2\), which are handled in two different ways. Actually, in the right upper corner we have a choice between two sequences

\[
q^6[N - 2] \implies q^7[N - 2]
\]

\[
q^5[N - 2] \implies q^6[N - 2]
\]

\[
q^4[N - 2] \implies q^5[N - 2]
\]

\[
q^2[N - 1] \implies q^3[N - 1]
\]
If all the arrows are horizontal, this is cohomologically equivalent to

\[ q^4 - N \implies q^{7-N} \implies q^{N+1} \implies q^{N+2} \implies q^{N+3} \implies q^{N+4} \]  \hspace{1cm} (6.87)

If we took two diagonal arrows instead, we would rather get

\[ q^4 - N + q^6 - N \implies q^{7-N} + q^{7-N} \implies q^{8-N} \implies q^{N+1} \implies q^{N+2} \implies q^{N+3} \implies q^{N+4} \]

i.e. more terms would remain, thus the horizontal arrows is the right choice. These substitutions (6.87) convert our table (6.85) into

| \( q^N \times \) | \( q \) | \( q^2 \) | \( q^3 \) | \( q^4 \) |
| \( q^{-N} \times \) | \( q^7 \) | \( q^8 \) | \( q^9 \) |
| \( q^{-N} \times \) | \( \frac{1}{q} \cdot q^2 \) | \( 2q^2 \cdot q^2 \) | \( 2q \cdot q^2 \) | \( q^2 \cdot q^2 \) |
| \( q^{-N} \times \) | 0 | 0 | 2q^2 | 2q^3 | 2q^4 | 2q^5 |

The first two lines come from (6.87), the third line – from application of (6.86). Putting all the terms from the last two lines into one, we get:

| \( q^N \times \) | \( q \) | \( q^2 \) | \( q^3 \) | \( q^4 \) |
| \( q^{-N} \times \) | \( q^7 \) | \( q^8 \) | \( q^9 \) |
| \( q^{-N} \times \) | 0 | 0 | 2q^2 | 2q^3 + q | 2q^4 + 2q^5 | 2q^5 + 2q^3 | q^4 |

and eliminating the cohomologically trivial pairs in this new line,

\[ q^{2-2N} + [N - 1] \cdot \hspace{1cm} (6.88) \]

| \( q^N \times \) | \( q \) | \( q^2 \) | \( q^3 \) | \( q^4 \) |
| \( q^{-N} \times \) | \( q^7 \) | \( q^8 \) | \( q^9 \) |
| \( q^{-N} \times \) | 0 | 0 | q^2 | q^3 \[2\] | q^4 \[2\] |

Now we have three increasing sequences and time comes to multiplication by \([N - 1]\) and further elimination of cohomologically trivial parts. This is already a standard procedure in this paper, the only new point is that in the middle sequence we have a jump in power by three between \( q^4 \) and \( q^7 \), and \( q^4[N - 1] \implies q^7[N - 1] \) is substituted by \( q^{8-N} + q^{6-N} = q^{7-N} \[2\] \implies q^{N+5} + q^{N+3} = q^{N+4} \[2\] \). Similarly, in unreduced case – which splits at this step – we substitute \( q^4[N] \implies q^7[N] \) by \( q^{7-N} + q^{5-N} = q^{6-N} \[2\] \implies q^{N+6} + q^{N+4} = q^{N+5} \[2\].
Continuing with the unreduced case, we obtain

\[
\begin{array}{c|ccc|ccc}
q^{2N} \times & q^2 & q^4 & q^2 & q^4 & q^2 & q^2 \\
1 \times & q^3 & q^{-1} & q^2 & q^{-1} & q^3 & q^{-1} \\
q^{-2N} \times & 0 & 0 & q^9 & q^9 & q^9 & q^9 \\
\end{array}
\]

This table is the answer:

\[
\mathcal{P}_{[3,5]}^{[3,5]} = q^{10(N-1)} \left( q^{2-2N} + q^{4-2N}(qT)^2 + q^4(qT)^3 + q^{5-2N}[2](qT)^4 + q^2[2](qT)^5 + q^{7-2N}[2](qT)^6 + (2q^3 + q^5)(qT)^7 + (q^{2N} + q^{10-2N})(qT)^8 + q^6[2](qT)^9 + q^{2+2N}(qT)^{10} \right) = q^{8(N-1)} \left( 1 + (q^4T^2 + q^2T^3a^2) \left( 1 + q^3[2]T^2 + q^7[2]T^4 \right) + q^8T^7a^2 + (q^{10} + q^6a^4)T^8 + q^{13}[2]T^9a^2 + q^{10}T^{10}a^4 \right)
\]

with \( a = q^N \), what is in perfect agreement with (159) of [56].

In unreduced case (6.88) is multiplied by \([N]\), and in the further transformations we use \([N]\) instead of \([N-1]\), so that (6.3.14) is changed for

\[
\begin{array}{c|ccc|ccc}
q^{2N} \times & q^2 & q^4 & q^2 & q^4 & q^2 & q^2 \\
1 \times & q^3 & q^{-1} & q^2 & q^{-1} & q^3 & q^{-1} \\
q^{-2N} \times & 0 & 0 & q^9 & q^9 & q^9 & q^9 \\
\end{array}
\]

and unreduced KR polynomial is

\[
\mathcal{P}_{[3,5]}^{[3,5]} = q^{10(N-1)} \left\{ q^{2-2N}[N] + \left( q^{3-2N}(qT)^2 + q^2(qT)^3 + q^{4-2N}[2](qT)^4 + q^2[2](qT)^5 + q^{6-2N}[2](qT)^6 + (q^2 + q^4 + q^6)(qT)^7 + (q^{2N+1} + q^{9-2N})(qT)^8 + (q^4 + q^8)(qT)^9 + q^{3+2N}(qT)^{10} \right) \right\} \cdot [N-1] (6.91)
\]

Like in the [3, 4] case, there is nothing to compare this formula with – it is new. However, eq.(6.91) will be confirmed in sec.8. To get superpolynomial, one makes the substitutions

\[
q^N = a, \quad [N - p] = \frac{q^{2p} + a^2T}{q^{p-1}(1 - q^2)a} \quad (6.92)
\]

(assuming that quantum numbers \([N - p]\) are independent variables – not made out of \(q^N\)).

**6.3.15 The link [3, 6]**

This time the table is
We shall see a little later that a few more cohomologically trivial combinations should be kept in this table in order to reproduce the known superpolynomial, but for a while we can continue with the table in its present form.
The next iteration:

$$q^{2-2N} + [N - 1] \cdot$$

|       | $[N - 2] \times$ | $q^9$ |
|-------|------------------|-------|
| $q^N \times$ | $q$ | $q^2$ |
| $q^{-N} \times$ | $q^4$ | $q^3$ |
| $q^{-N} \times$ | $\frac{1}{q} \cdot q^2$ | $2q^2$ |
| $q^{-N} \times$ | $2q \cdot q^2$ | $q^2 \cdot q^2$ |
| $q^{-N} \times$ | $0$ | $0$ |

and further, eliminating one overlined pair and inserting three underlined ones,

$$q^{2-2N} + [N - 1] \cdot$$

|       | $[N - 2] \times$ | $q^9$ |
|-------|------------------|-------|
| $q^N \times$ | $q$ | $q^2$ |
| $q^{-N} \times$ | $q^4$ | $q^3$ |
| $q^{-N} \times$ | $0 + q^6[2]$ | $q^7[2] + q^5[2]$ |
| $q^{-N} \times$ | $0 + q^9$ | $2q^{10} + q^8$ |

$$\sim q^{2-2N} +$$

|       | $[N - 1][N - 2] \times$ | $q^9$ |
|-------|------------------|-------|
| $q^N[N - 1] \times$ | $(2q^2 + 1) \cdot q^3$ |
| $q^{2N} \times$ | $1$ | $q^2$ |
| $1 \times$ | $q^3$ | $q^5$ |
| $1 \times$ | $q^4[2]$ | $q^7$ |
| $q^{-2N} \times$ | $q^7[2]$ | $q^{10}$ |
| $q^{-N}[N - 1] \times$ | $0$ | $(2q^2 + 1) \cdot q^4$ |

Insertions are allowed, because there were many terms of this kind at these places in original table from sec.6.3.13.

Insertions are needed to provide the right answer for the superpolynomial.

Indeed, from the last table we read:

$$P_l^{[3,6]} = q^{12N - 12} \left( q^{2-2N} + q^{4-2N}(qT)^2 + q \cdot (qT)^3 + q^{5-2N}[2](qT)^4 + q^2[2](qT)^5 + q^{7-2N}[2](qT)^6 + \right.$$

$$+ (q^4[2] + q^3)(qT)^7 + (q^{2N} + q^{10-2N})(qT)^8 + q^6[2](qT)^9 + q^{2N+2}(qT)^{10} +$$

$$+ (2q^2 + 1) \left( q^{4-N}(qT)^8 + q^{8-N}(qT)^{10} + q^{N+3}(qT)^{11} \right) (N - 1) + q^9[N - 1][N - 2](qT)^{12} \right)$$

(6.94)
Using the rules (6.92) we obtain \( q^{10(N-1)} \) times:

\[
1 + q^4T^2 + q^2a^2T^3 + q^1[2]T^4 + q^5a^2T^5 + q^7[2]T^6 + (q^9[2] + q^8)a^2T^7 + \ (q^{16} + q^6a^4)T^8 + q^{13}[2]a^2T^9 + q^{10}a^4T^{10} + \\
(2q^2 + 1)\left(q^{10}T^8 + q^{16}T^{10} + q^{12}a^2T^{11}\right) q^2 + a^2T \left(1 - q^2\right) + q^{18}T^{12}\left(\frac{(q^2 + a^2T)(q^4 + a^2T)}{q^N[N-1]}\right) \left(1 - q^2\right)^2 q^{2N+1}[N-1][N-2] (6.95)
\]

what is the right answer from eq.(148) of [56].

As usual, only the terms in the first two lines of (6.94) are seriously affected in the switch to the unreduced KR polynomial, while the last line is just multiplied by \([N]\):

\[
\mathcal{P}^{[3,6]} = q^{10N-10}[N] + \left(\frac{q^3T^2 + q^22N+3T^3 + q^6[2]T^4 + q^22N+6[2]T^5 + q^10[2]T^6}{q^{2N+9}[3]}\right) \\
+ \left(\frac{q^{10}[2] + q^7T^7 + \left(q^{4N+7} + q^{15}\right)T^8 + \left((q^{11} + q^{15})q2N0 + q^{4N+11}T^{10}\right)}{q^{2N+11}[q^2+q^2]}\right) [N - 1] + \\
(2q^2 + 1)\left(q^{N+10}T^8 + q^{N+16}T^{10} + q^{3N+12}T^{11}\right) [N][N - 1] + q^{2N+19}T^{12}[N][N - 1][N - 2] \right) \right) \left(\frac{q^2 + a^2T}{1 - q^2}\right)^2 \left(1 - q^2\right)^2 (6.96)
\]

Note that in each of the underbraced terms the power of \(q\) in one item increases by one, while decreases in another item.

We return to generic consideration of generic \([3, n]\) knots and links in section 8, where a more powerful technique will be applied.

### 6.4 Some other families of 3-strand knots and links

In what follows we use the general notation \((a_1, b_1|a_2, b_2|a_3, b_3|\ldots)\) for the 3-strand braid \(R_1^{a_1}R_2^{b_1}R_3^{a_2}R_2^{b_2}R_1^{a_3}R_2^{b_3} \ldots\)

In this notation the torus braid is \([3, n] = (1, 1)^n\), while the figure-eight knot \(4_1\) is associated with \((1, -1)^2\).

#### 6.4.1 \(R_1^n\): back to two-strands

In this case the third strand is actually unlinked with the other two, so the answer should be a product of 2-strand knot/link and an unknot \([N]\). Another obvious feature is that already the very first differential \(d_0\) is made only of the morphism \(\alpha_1\), with no \(\alpha_2\) – as we know this implies that the kernel of \(d_0\) is \(N\)- rather than 1-component. It is instructive to see how this works in the general context of 3-strand links.

In this case all the spaces at hypercube vertices are of the type

\[ v_{k0} = [2]^{k-1}[N][N - 1] = q[2]^{k-1}\left([N - 1] + q^{-N}\right) [N - 1] \]

In particular, no \([N - 2]\) factors show up. The primary polynomial is

\[
q^{-n(N-1)} , \mathcal{P}^{[n,0]}_T = q^{2-2N} + [N - 1] . \]

Underlined term (one unit out of two) will contribute to the zeroth cohomology. To understand what are the other contributions, consider some particular example, say, \(n = 5\):
Contributing to cohomologies are underlined terms, which form our familiar increasing pairs, \(q^k[N - 1] \implies q^{k+1}[N - 1]\), which we substitute by \(q^{k+2-N} \implies q^{N+k-1}\). In unreduced case the similar substitution will be \(q^k[N] \implies q^{k+1}[N]\) by \(q^{k+1-N} \implies q^{N+k}\). Thus the answer is:

\[
q^{-n(N-1)} \cdot P_r^{(n,0)} = \frac{q^{2-2N} + q^{-N}[N - 1] \cdot q^2 + q^{-N(N-1)+q^{-N}} = q^{2-N}[N]}{q^{2-N}(q^2 + q^{-N})^2 + q^{6-N}(q^2 + q^{-N})^4 + q^{N+3}(q^2 + q^{-N})^5 + \ldots} (6.98)
\]

i.e.

\[
P_r^{(n,0)} = q^{(n-1)(N-1)}[N] \left\{ 1 + q^{N-2} \left( q^{4-N}(q^2 + q^{-N})^2 + q^{6-N}(q^2 + q^{-N})^4 + \ldots \right) + q^{N-2} \left( q^{N+1}(q^2 + q^{-N})^3 + q^{N+3}(q^2 + q^{-N})^5 + \ldots \right) + \ldots \right\} + \frac{q^n \cdot (q^N)^n [N - 1]}{\text{for even } n} (6.99)
\]

where we easily recognize (5.59). Note that this time the factor \([N]\) remains and is not traded for \([N - 1]\) in the process of eliminating of cohomologically trivial part – we proceed in exactly the same way as with the other 3-strand knots and do not pay attention to unification of \([N - 1]\) and \(q^{-N}\) into \(q^{2-N}\) at intermediate stages. The remaining overall factor \([N]\) describes the independent unknot component of the 3-strand link \(R_1^3\).

For unreduced KR polynomial we get instead:

\[
P^{(n,0)} = q^{(n-1)(N-1)}[N] \left\{ [N] + q^{N-2}[N - 1] \left( q^{3-N}(q^2 + q^{-N})^2 + q^{5-N}(q^2 + q^{-N})^4 + \ldots \right) + q^{N-2}[N - 1] \left( q^{N+2}(q^2 + q^{-N})^3 + q^{N+3}(q^2 + q^{-N})^4 + \ldots \right) + \frac{q^n \cdot (q^N)^n [N][N - 1]}{\text{for even } n} \right\} (6.100)
\]

– and this is in accordance with (5.61) and (5.62).
6.4.2 \( \mathcal{R}_1^m \mathcal{R}_2^n \): still no \([N - 2]\) – composites

In this family all spaces are of the types \(v_{k0} = [2]^{k-1}[N][N - 1]\) and \(v_{k1} = [2]^{k-2}[N - 1]^2\) – this is the most general case, when no contributions with \([N - 2]\) factors appear in expressions for KR polynomials. Actually this family consists of composite links and knots, but it includes a number of examples which we already examined in other braid representations, therefore its analysis can also serve as an illustration of topological invariance of our formalism.

From now on we use the following pictorial representation of the braid:

\[
\begin{array}{ccccccc}
\cdot & \cdot & \ldots & \cdot & \cdot & \ldots & \cdot \\
& & & & \cdot & \cdot & \ldots \\
\end{array}
\]

Black and white dots show relative positions of matrices \(\mathcal{R}_1^{\pm1}\) and \(\mathcal{R}_2^{\pm1}\) – in the first and the second lines respectively. In our current examples there are no white dots, and there are \(n\) black in the first line and \(m\) black in the second line.

The primary polynomial for this family has the following form:

\[
q^{-(n+m)(N-1)} \cdot \mathcal{P}_r^{(n,m)} = q^{2-2N} + [N - 1] \cdot + \[N - 1] \cdot + \]

\[
\begin{array}{ccccccc}
1 & qT & \ldots & (qT)^k & \ldots & (qT)^{n+m} \\
\hline
[N - 1] \times & q^2 (n + m)q & \ldots & [2]^{k-2} q^2 (C_n^k + C_m^k) & \ldots & [2]^{n+m-2} \\
q^{-N} \times & 2q^2 (n + m)q & \ldots & q[2]^{k-1} (C_n^k + C_m^k) & \ldots & 0 \\
\end{array}
\]

As usual, to understand the structure of reduction to KR polynomials, we consider examples.

\(\mathcal{R}_1 \mathcal{R}_2\) – unknot (torus knot \([3, 1]\))

\[
\begin{array}{cccccc}
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\hline
[N - 1] \times & q^2 & 2q & 1 \\
q^{-N} \times & 2q^2 & 2q & 0 \\
\end{array}
\]

\[
\sim q^{2-2N} \quad (6.102)
\]

since the table contains two cohomologically trivial sequences. Thus \(\mathcal{P}_r^{(1,1)} = 1\) and \(\mathcal{P}^{(1,1)} = [N]\).

\(\mathcal{R}_1^2 \mathcal{R}_2\) – Hopf link

\[
\begin{array}{cccccc}
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\hline
[N - 1] \times & q^2 & 3q & 2 + q[2] & [2] \\
q^{-N} \times & 2q^2 & 3q & q[2] & 0 \\
\end{array}
\]

\[
\sim q^{2-2N} + q^{-N}[N - 1] \cdot q^2 \cdot (qT)^2
\]

\[
(6.103)
\]

57
The only element inside the table, which contributes to cohomologies is boxed. Thus $P_r^{(2,1)} = q^N - 1 \left(1 + q^{N+2}T^2 \right)[N - 1]$ and $P^{(2,1)} = [N]P_r^{(2,1)}$

$R_2 \times R_2$ — trefoil

$\begin{array}{|c|c|c|c|c|}
\hline
\text{ } & 1 & qT & (qT)^2 & (qT)^3 & (qT)^4 \\
\hline
q^{-N} \times & 0 & 0 & q^2 & q^3 & 0 \\
\hline
\end{array}$

$\sim q^{2-2N} + [N - 1] \cdot q^{-N} \times q^{2-2N} + [N - 1] \cdot q^{-N}$

since the first line in the first table is cohomologically trivial. Thus $P_r^{(3,1)} = q^{2N-2} \left(1 + q^4T^2 + q^{2N+2}T^3 \right)$ and $P^{(3,1)} = q^{2N-2} \left([N] + (q^3T^2 + q^{2N+3}T^3)[N - 1] \right)$.

$R_2 \times R_2$ — the torus link [2, 4] or $4_1(\nu 2)$ of [43]

$\begin{array}{|c|c|c|c|c|c|c|}
\hline
\text{ } & 1 & qT & (qT)^2 & (qT)^3 & (qT)^4 \\
\hline
q^{-N} \times & 0 & 0 & q^2 & q^3 & 0 \\
\hline
\end{array}$

$\sim q^{2-2N} + q^{-N} \left(q^{4-N}(qT)^2 + q^{N+1}(qT)^3 \right)$

$\sim q^{2-2N} + [N - 1] \cdot q^{-N} \times q^{2-2N} + [N - 1] \cdot q^{-N} \times q^{2-2N} + [N - 1] \cdot q^{-N}$

where we left unpaired the last element in the second table — as usual. Thus

$P_r^{(4,1)} = q^{3N-3} \left(1 + q^4T^2 + q^{2N+2}T^3 + q^{N+6}T^4 \right)[N - 1]$,

$P^{(4,1)} = q^{3N-3} \left([N] + (q^3T^2 + q^{2N+3}T^3)[N - 1] + q^{N+6}T^4[N][N - 1] \right)$ (6.104)

$R_2 \times R_2$ — 2-strand torus knots and links [2, n]
From above examples it is already clear what the entire series \((n, 1)\) is going to be:

\[
q^{-(n+1)(N-1)} \cdot \mathcal{P}^{(n, 1)}_r \sim q^{2-2N} + [N - 1].
\]

| \(1\) | \(qT\) | \((qT)^2\) | \((qT)^3\) | \(\ldots\) | \((qT)^n\) | \((qT)^{n+1}\) |
|------|------|--------|--------|-----|--------|--------|
| \(q^{-N}\times\) | 0   | 0      | \(q^2\) | \(q^3\) | \(\ldots\) | \(q^n\) | 0           |

(6.105)

Now the answer depends on whether \(n\) is odd (knots) or even (links): in the former case all the items in the table come in pairs and

\[
\mathcal{P}^{(2k+1, 1)}_r = q^{2k(N-1)} \left(1 + q^4T^2 + q^{2N+2}T^3 + q^{6}T^4 + q^{2N+6}T^5 + \ldots + q^{4k}T^{2k} + q^{2N+4k-2}T^{2k+1}\right),
\]

\[
\mathcal{P}^{(2k+1, 1)} = q^{2k(N-1)} \left([N] + \left(q^{3}T^2 + q^{2N+3}T^3 + q^{7}T^4 + q^{2N+7}T^5 + \ldots + q^{4k-1}T^{2k} + q^{2N+4k-1}T^{2k+1}\right)[N - 1]\right) = q^{2k(N-1)} \left([N] + \frac{1}{q}\left(q^{4T^2} + (q^{4T^2})^2 + \ldots + (q^{4T^2})^k\right)(1 + q^{2NT})[N - 1]\right)
\]

while in the latter case the last term remains unpaired and

\[
\mathcal{P}^{(2k, 1)} = q^{(2k-1)(N-1)} \left(1 + q^4T^2 + q^{2N+2}T^3 + q^{6}T^4 + q^{2N+6}T^5 + \ldots + q^{4k-4}T^{2k-2} + q^{2N+4k-6}T^{2k-1} + q^{N+4k-2}T^{2k}[N - 1]\right) = q^{N-1} \cdot \mathcal{P}^{(2k-1, 1)}_r + q^{2kN+2k-1}T^{2k}[N - 1],
\]

\[
\mathcal{P}^{(2k, 1)} = q^{(2k-1)(N-1)} \left([N] + \left(q^{3}T^2 + q^{2N+3}T^3 + q^{7}T^4 + q^{2N+7}T^5 + \ldots + q^{4k-5}T^{2k-1} + q^{2N+4k-5}T^{2k-1}\right)[N - 1] + q^{N+4k-2}T^{2k}[N][N - 1]\right) = q^{N-1} \cdot \mathcal{P}^{(2k-1, 1)} + q^{2kN+2k-1}T^{2k}[N][N - 1]
\]

This family is of course equivalent to 2-strand torus knots \([2, n]\), since the first Reidemeister move is sufficient to eliminate the single \(R_2\). Thus above calculation – and agreement with (5.61) and (5.62) – is actually a check of invariance under the first Reidemeister move (within particular family).

In particular, for the knot 5_1 = [2, 5]

\[
\mathcal{P}^{5_1} = q^{4(N-1)} \left(1 + q^4T^2 + q^{2N+2}T^3 + q^{8}T^4 + q^{2N+6}T^5\right),
\]

\[
\mathcal{P}^{5_1} = q^{4(N-1)} \left([N] + \left(q^{3}T^2 + q^{2N+3}T^3 + q^{7}T^4 + q^{2N+7}T^5\right)\right)
\]

(6.106)

and for the link \([2, 6]\) = 6_1(v1) of [43]

\[
\mathcal{P}^{[2, 6]} = q^{5(N-1)} \left(1 + q^4T^2 + q^{2N+2}T^3 + q^{8}T^4 + q^{2N+6}T^5 + q^{N+10}T^{6}[N - 1]\right),
\]

\[
\mathcal{P}^{[2, 6]} = q^{5(N-1)} \left([N] + \left(q^{3}T^2 + q^{2N+3}T^3 + q^{7}T^4 + q^{2N+7}T^5\right)[N - 1] + q^{N+10}T^{6}[N][N - 1]\right)
\]

(6.107)

– what reproduces the answers from [43] (for unreduced \(\mathcal{P}^{[6,2]}\) it was found there only for \(n = 2, 3, 4\)).
\( R^2 R^2 \) – composite of two Hopf links

\[ q^{-4(N-1)} \cdot P_r^{(2,2)} = q^{2-2N} + [N - 1] \cdot \]

\[ [N - 1] \times \begin{array}{c}
q^2 \\
q^{-N}
\end{array}
\begin{array}{cccc}
0 & 0 & 0 & 0 \\
0 & 2q^2 & 0 & 0
\end{array}
\]

\[ \sim q^{2-2N} + [N - 1] \left( 2q^{2-N}(qT)^2 + q^2[N - 1](qT)^4 \right) \]

and reduced KR polynomial

\[ P_r^{(2,2)} = q^{2N-2} \left( 1 + 2q^{N+2T}[N - 1] + q^{2N+4T^2}[N - 1]^2 \right) = \left\{ q^{N-1} \left( 1 + q^{N+2T^2}[N - 1] \right) \right\}^2 = \left\{ P_r^{(2,1)} \right\}^2 \]

is the square of reduced KR polynomial for the Hopf link – as it should be for reduced knot/link polynomials.

Unreduced polynomial factorizes into a product of reduced and unreduced ones:

\[ P^{(2,2)} = [N] \cdot P_r^{(2,2)} \cdot P_r^{(2,1)} \]

(6.109)

Generic \( R^1 R^n \) – a composite of two 2-strand knots/links

Now it is clear that the same will be true in general. Like HOMFLY, the reduced KR polynomial for a composition just factorizes into a product of reduced polynomials for the constituents:

\[ P_r^{(n,m)} = P_r^{(n,1)} \cdot P_r^{(m,1)} \cdot P_r^{[2,n]} \cdot P_r^{[2,m]} \]

(6.110)

In unreduced case things can be more complicated. Even for HOMFLY the product of two unreduced polynomials exceeds the polynomial for a composite by a factor of [N]. Within the \((n, m)\) family a natural possibility would be

\[ P^{(n,m)} \geq P^{[2,n]} \cdot P_r^{[2,m]} \]

(6.111)

In such a relation unreduced is preferably the polynomial with \( n \geq m \) – clearly this product is smaller than its alternative if unreduced is the factor with \( n < m \) (since the bigger \( n \) the more is the gain in diminishing unreduced polynomial from \([N]\) times the unreduced one). However, as we shall see, there are few chances for this formula to hold even within the \((n, m)\) family. Moreover, if morphisms are not fully specified, sometime it seems possible to have even a smaller polynomial – and the right unreduced KR polynomial can lie in between that minimal one and (6.111).

To illustrate the situation we consider two more examples.
\[ R_4 R_2 \]

\[ q^{-6(N-1)} \cdot P_r^{(4,2)} = q^{2-2N} + [N - 1] \cdot \]

| \[ q^4 \] | \( q^4 \) | \( 6q^3 \) | \( 4q^2 \) |
| \( q^2 \) | \( 6q \) | \( 15 \) | \( \frac{20}{q} \) | \( \frac{15}{q^2} \) |
| \( q^{-N} \) | \( 2q^2 \) | \( 6q \) | \( 7 \) | \( \frac{4}{q} \) | \( \frac{1}{q^2} \) |

Underlined are the terms that we choose to contribute to cohomologies, and the boxed element goes directly to the KR polynomial. The underlined pair in the upper part of the table

\[ q^2[N - 1] \implies q^3[N - 1] \]

is substituted by \( q^{4-N} \implies q^{N+1} \),

so that the next iteration is

\[ q^{2-2N} + q^4[N - 1]^2 \cdot (qT)^6 + q^{N+1}[N - 1](qT)^5 + q^{-N}[N - 1] \cdot \]

\[
\begin{array}{cccccc}
0 & 0 & 2q^2 & q^3 & 2q^4 & 0 & 0
\end{array}
\]

Underlined are the terms which we are going to reduce by the rule (6.112), and the result is

\[
P_r^{(4,2)} = q^{4N-4} \left\{ 1 + q^4T^2 + q^2T^2 + \left( q^{N+2}T^2 + 2q^{N+6}T^4 + q^{3N+4}T^5 \right)[N - 1] + q^{2N+8}T^6[N - 1]^2 \right\} =
\]

\[ q^{N-1} \left( 1 + q^N+2T^2[N - 1] \right) \cdot q^{3N-3} \left( 1 + q^4T^2 + q^{2N+2}T^2 + q^{N+6}T^3[N - 1] \right) = P_r^{(2,1)} \cdot P_r^{(4,1)} \]

(6.113)

What we need to modify in unreduced case is the rule (6.112), which was used in two places. Therefore

\[
P_r^{(4,2)} = q^{4N-4} \left\{ [N] + \left( q^3T^2 + q^{2N+3}T^3 \right)[N - 1] + \left( q^{N+5}T^4 + q^{3N+5}T^5 \right)[N - 1]^2 + \right. \\
+ \left( q^{N+2}T^2 + q^{N+6}T^4 \right)[N][N - 1]q^{2N+8}T^6[N][N - 1]^2 \right\} =
\]

\[ q^{3N-3} \left\{ [N] + \left( q^3T^2 + q^{2N+3}T^3 \right)[N - 1] + q^{N+6}T^4[N][N - 1] \right\} \cdot q^{N-1} \left( 1 + q^{N+2}T^2[N - 1] \right) = P_r^{(4,1)} \cdot P_r^{(2,1)}
\]

This equation confirms the rule (6.111).

Alternative product \( P^{(2,1)} \cdot P_r^{(4,1)} \), where unreduced is the polynomial with the smaller \( m < n \), would in this case imply that unreduced polynomial is just \([N] \cdot P_r^{(4,2)}\) and is clearly bigger than the true unreduced \( P^{(4,2)}\).
This time four terms in the upper part of the table come in two pairs and we substitute

\[ [N - 1] \cdot (q^2 \implies q^3 \implies q^4 \implies q^5) \]

by

\[ q^{4-N} \implies q^{N+1} \cdot q^{-N} \implies q^{N+2} \implies q^{6-N} \implies q^{N+3} \]

Repeating this once again for the two freshly underlined terms, we substitute \( q^N[N - 1] \cdot (q \implies q^2) \) by \( q^3 \implies q^{2N} \), and the next iteration is

\[
q^{-7(N-1)} \cdot \mathcal{P}_r^{(4, 3)} \sim q^{2-2N} + q^3 \cdot (qT)^5 + q^{2N} \cdot (qT)^6 + q^{N+3}[N - 1] \cdot (qT)^7 + q^{-N}[N - 1] \cdot \begin{array}{cccccc} 0 & 0 & 2q^3 & 2 & q_4^2 & q_5^3 \end{array} [6.115]
\]

In this small table we need to pick up to terms, which contributes to cohomologies straightforwardly – as usual these should stand as far to the right as only possible, i.e. these are the two items in boxes. Other terms in the table can be further simplified with the help of (6.112) to provide

\[
q^{N-6} \left( 2q^{4-N} \implies 2q^{N+1} \implies q^{6-N} \implies q^{N+3} \right),
\]

and finally

\[
\mathcal{P}_r^{(4, 3)} = q^{5N-5} \left\{ 1 + 2q^4T^2 + 2q^{2N+2}T^3 + q^8T^4 + q^{2N+6}T^5 + q^{N-2} \left[ q^4(qT)^4 + q^6(qT)^6 \right][N - 1] + q^{2N-2} \left[ q^3 \cdot (qT)^5 + q^{2N} \cdot (qT)^6 + q^{N+3}[N - 1] \cdot (qT)^7 \right] \right\} = q^{5N-5} \left\{ 1 + 2q^4T^2 + 2q^{2N+2}T^3 + q^8T^4 + q^{2N+6}T^5 + q^{4N+4}T^6 + \left[ q^{N+6}T^4 + q^{N+10}T^6 + q^{3N+8}T^7 \right][N - 1] \right\} = q^{2N-2} \left( 1 + q^4T^2 + q^{2N+2}T^3 \right) \cdot q^{3N-3} \left( 1 + q^4T^2 + q^{2N+2}T^3 + q^{N+6}T^4[N - 1] \right) = \mathcal{P}_r^{(3, 1)} \cdot \mathcal{P}_r^{(4, 1)} [6.116]
\]
In unreduced case we get instead
\[ q^{7-7N} \mathcal{P}^{(4,3)} \sim q^{2-2N} [N] + [N][N-1]^{2} \left( 0 \ 0 \ 0 \ 0 \ q^2 \ 2q^3 \ 2q^4 \ q^5 \right) + q^{-N}[N][N-1] \left( 0 \ 0 \ 2q^2 \ 2q^3 \ q^4 \ 0 \ 0 \ 0 \right) \]

In the second bracket we reduce the underlined pair to
\[
\begin{pmatrix}
0 & 0 & 2q^{3-2N}[N-1] & 2q^2[N-1] & q^{4-N}[N][N-1] & 0 & 0 & 0
\end{pmatrix}
\]

(6.117)

As to the first bracket, there are different reduction options now (if we do not specify the morphisms from general principles).

The minimal option is to first get rid of $[N]$ (rather than $[N-1]$) whenever possible. Then the next iterations of the first bracket are:

\[
[N-1]^{2} \begin{pmatrix}
0 & 0 & 0 & 0 & q^{N+2} & q^{N+3} & q^{N+4} \\
q^{3-N} & q^{4-N} & \end{pmatrix}
\sim
\begin{pmatrix}
0 & 0 & 0 & 0 & q^{4}[N-1] & q^{2N+1}[N-1] & q^{N+4}[N-1]^{2} \\
q^{3-N}[N-1]^{2} & q^{4-N}[N-1]^{2} & q^{5-N}[N-1]^{2} & \end{pmatrix}
\]

(6.118)

The underlined items in (6.117) and (6.118) are transformed from $q^{4-N}[N][N-1] \Rightarrow q^{4-N}[N-1]^{2}$ to $q^{2-2N}[N-1] \Rightarrow 0$ and we get the hypothetical unreduced polynomial
\[
\mathcal{P}\mathcal{P}^{(4,3)} \sim q^{5N-5} \left[ [N] + (2q^{3}T^{2} + q^{7}T^{4})(1 + q^{2N}T)[N-1] + q^{4N+5}[N-1]T^{6} + q^{N+5}T^{4}[N-1]^{2} \right] \left( 1 + q^{4}T^{2} + q^{2N+4}T^{3} \right)
\]

This expression gets proportional to $[N]$ at $T = -1$, but clearly it is too ugly to be a right answer (implied by the true morphisms, once they will be specified).

Thus we sacrifice extreme minimality and proceed instead in our usual way – postponing the reduction with the help of $[N]$ rather than $[N-1]$ to the very last step. This means that the first bracket is rather converted into:

\[
[N][N-1] \begin{pmatrix}
0 & 0 & 0 & 0 & q^{N+1} & q^{N+2} & q^{N+3} \\
q^{4-N} & q^{5-N} & \end{pmatrix}
\sim
\begin{pmatrix}
0 & 0 & 0 & 0 & q^{2}[N-1] & q^{2N+1}[N-1] & q^{N+3}[N][N-1] \\
q^{3-N}[N][N-1] & q^{5-N}[N][N-1] & q^{6-N}[N][N-1] & \end{pmatrix}
\]

(6.119)

Now the underlined items (6.117) and (6.119) are transformed from $q^{4-N}[N][N-1] \Rightarrow q^{5-N}[N][N-1]$ to $q^{2-2N}[N-1] \Rightarrow q^{4}[N-1]$ and

\[
\mathcal{P}\mathcal{P}^{(4,3)} \sim q^{3N-5} \left[ [N] + \left( 2q^{3}T^{2} + q^{7}T^{4} + q^{2N+5}T^{5} \right)(1 + q^{2N}T)[N-1] + q^{N+6}T^{4} \right] \left( 1 + q^{4}T^{6} + q^{2N+2}T^{3} \right)[N][N-1]
\]

This version looks somewhat more plausible, despite it is bigger than the previous one. Finally, the product (6.111) is even bigger:

\[
\mathcal{P}\mathcal{P}^{(4,1)} \cdot \mathcal{P}\mathcal{P}^{(3,1)} = q^{3N-3} \left[ [N] + \left( q^{3}T^{2} + q^{2N+3}T^{3} \right)[N-1] + q^{N+6}T^{4}[N][N-1] \right] \cdot q^{2N-2} \left( 1 + q^{4}T^{2} + q^{2N+2}T^{3} \right)
\]

In particular, the terms $q^{3}T^{2}$ here will enter with the coefficient $q[N] + [N-1] = 2[N-1] + q^{N} > 2[N-1]$.

Thus we confirmed once again the general formula (6.110), describing reduced KR polynomials for the family $\mathcal{R}_{1} \mathcal{R}_{2}^{0}$ of composite knots and links, made from a pair of the 2-strand ones. As to unreduced KR polynomials for composites, the question remains open: though (6.111) holds in some examples, it is hardly true even within the $(n, m)$ family and has much less chances to work in general, where there is no natural ordering between the constituents of the composite. Most probably there is no universal rule for building unreduced KR polynomials for composites from those of their constituents.
6.5 Five intersections

6.5.1 The 2-component link $R_1R_2R_1R_2R_1$ (the torus $[2, 4]$ or $4_1^2(v2)$ of [43])

The primary polynomial, associated with the braid

\[
\begin{array}{c}
\bullet \\
\bullet \\
\bullet \\
\bullet
\end{array}
\]

is described by the following table:

|            | $v_{0,0}$ | $\rightarrow$ | $5v_{10}$ | $\rightarrow$ | $4v_{20} + 6v_{21}$ | $\rightarrow$ | $v_{30} + 9v_{31}$ | $\rightarrow$ | $3v_{41} + 2v_{42}$ | $\rightarrow$ | $v_{52}$ |
|------------|-----------|---------------|-----------|---------------|-------------------|---------------|-------------------|---------------|-------------------|---------------|---------|
| $[N-1]$ $\times$ |           |               |           |               | $q^3$            |               | $3q^2$            |               | $q$               |               | $q^2$ |
| $[N-2]$ $\times$ |           |               |           |               | $4q^2$           |               | $11q$            |               | $8$               |               | $\frac{1}{q}$ |
| $[N-1]$ $\times$ |           |               |           |               | $q^2$            |               | $5q$             |               | $10$              |               | $\frac{3}{q}$ |
| $[N-2]$ $\times$ |           |               |           |               | $2q^2$           |               | $5q$             |               | $4$               |               | $\frac{1}{q}$ |
| $q^{-N}$ $\times$ |           |               |           |               | $4q^2$           |               | $2q$             |               | $q^3$            |               |         |

$\sim q^{2-2N} + [N-1] \cdot$

\[
\begin{array}{c|c|c|c|c|c}
[N-1] $\times$ & [N-2] $\times$ & \frac{1}{q} & \frac{1}{q} \\
\hline
q^{-N} $\times$ & 0 & 0 & 2$q^2$ & q & q^3
\end{array}
\]

$\sim q^{2-2N} + q^{-N}[N-1] \cdot$

\[
\begin{array}{c|c|c|c|c|c}
0 & 0 & 2$q^2$ & q & q^3 & 0
\end{array}
\]

$\sim q^{2-2N} + q^{-N}[N-1] \cdot$

\[
\begin{array}{c|c|c|c|c|c}
0 & 0 & q^2 & q^3 & q^4 & 0
\end{array}
\]

The two underlined items are handled according to the usual rule: $q^2[N-1] \Rightarrow q^3[N-1]$ is substituted by $q^4 \Rightarrow q$, and we finally obtain the reduced KR polynomial

\[
P_{r}^{3}(v2) = q^{5N-5} \left( q^{2-2N} + q^{4-2N}(qT)^2 + q \cdot (qT)^3 + q^{4-N} (qT)^4[N-1] \right) =
\]

\[
= q^{3N-3} \left( 1 + q^4T^2 + q^2 + q^{N+2}T^3 + q^{N+6}T^4[N-1] \right)
\]

and it indeed coincides with the answer for $4_1^2(v2)$ in [43].
In unreduced case we get instead
\[ P_{47}^{47(v^2)} = q^{3N-3} \left( [N] + q^3T^2[N-1] + q^{2N+3}T^3[N-1] + q^{N+6}T^4[N][N-1] \right) \] (6.121)
– again in accord with [43].

These two expressions are of course the same as (6.104) obtained in another raid representation of the same link.

6.5.2 Another initial coloring: the 2-component link \( R_1 R_2 R_1^{-1} R_2 R_1 \) (the torus [2, 4] with inverse orientation or \( 47(v^1) \) of [43])

The primary polynomial, associated with the braid
\[ \bullet \circ \bullet \]
is described by the following table:

\[
\left( \frac{q^{4N-4}}{q^{N+T}} \right)^{-1} P_{47}^{47(v^1)} = q^{2-2N} \cdot (qT) + [N-1].
\]

|       | \( v_{11} \) | \( v_{11} + 2v_{21} + 2v_{21} \) | \( 4v_{11} + 5v_{31} \) | \( 2v_{21} + 4v_{21} + 2v_{41} + 2v_{42} \) | \( 4v_{31} + v_{52} \) | \( v_{41} \) |
|-------|------------|------------------|----------------|------------------|----------------|------|
| \([N-1] \times q \) | \( q \) | \( q^2 + 2q[2] + 2 \) | \( 4q + q[2]^2 + 5[2] \) | \( 2q[2] + 4 + 2q[2]^2 + 2 \) | \( 4[2] + [2] \) | \([2]^2 \) |
| \([N-2] \times q \) | | | | \( 2[2] \) | | \([2]^2 \) |
| \(q^{-N} \times q \) | \( q \) | \( 2q^2 + 2q[2] \) | \( 4q + q[2]^2 \) | \( 2q[2] \) | | |

In more detail the table is

|       | \([N-1] \times q \) | \([N-2] \times q \) | \([N-1] \times q \) | \([N-2] \times q \) | \([N-1] \times q \) | \([N-2] \times q \) | \([N-1] \times q \) | \([N-2] \times q \) |
|-------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| \([N-1] \times q^3 \) | \( q^2 \) | \( q^2 \) | \( 4q^2 \) | \( 5q \) | \( 2q^{-1} \) | \( 5q^{-1} \) | \( q^{-2} \) | \( 2q^{-1} \) |
| \([N-1] \times \) | \( q^3 \) | \( 4q^2 \) | \( 5q \) | \( 2q^{-1} \) | \( 5q^{-1} \) | \( q^{-2} \) | \( 2q^{-1} \) | \( q^{-2} \) |
| \([N-2] \times q \) | \( 3q^2 \) | \( 11q \) | \( 12 \) | \( 2q^{-1} \) | \( 5q^{-1} \) | \( q^{-2} \) | \( 2q^{-1} \) | \( q^{-2} \) |
| \([N-2] \times q \) | | \( 4q \) | \( 6q^{-1} \) | \( 2q^{-2} \) | \( 6q^{-1} \) | \( 2q^{-2} \) | \( q^{-2} \) | \( (1) \) |
| \([N-2] \times q \) | | | \( q^{-1} \) | \( 2q^{-2} \) | \( q^{-2} \) | \( 2q^{-2} \) | \( 2q^{-2} \) | \( (1) \) |
| \([N-2] \times q \) | | | | \( q^{-1} \) | | \( q^{-2} \) | \( q^{-2} \) | \( (1) \) |
| \([N-2] \times q \) | | | | | \( 2q^{-2} \) | \( 2q^{-2} \) | \( 2q^{-2} \) | \( (1) \) |

Contributing to cohomologies are two underlined pairs in the upper part and one underlined element in the lower part of the table:
After multiplication by $[N-1]$ or $[N][N-1]$ (in the case of reduced and unreduced polynomials respectively) the two terms in the second line can be further reduced: $[N-1] (q \Rightarrow q^2)$ gets substituted by $q^{3-N} \Rightarrow q^N$ and $[N][N-1] (q \Rightarrow q^2)$ – by $[N-1] (q^{2-N} \Rightarrow q^{N+1})$. Therefore the KR polynomials are:

\[
\mathcal{P}^{4\zeta_2(v1)} = \frac{q^{3N-3}}{(qT)} \{ q^{2-2N} \cdot (qT) + q^{-N} \{ q^{3-N} (qT)^2 + q^N (qT)^3 \} + q^N [N-1](qT)^5 \} = q^{N-1} \{ 1 + q^2T + q^{2N}T^2 + q^{3N+2}[N-1]T^4 \},
\]

\[
\mathcal{P}^{4\zeta_1(v1)} = q^{N-1} \{ [N] + (qT + q^{2N+1}T^2)[N-1] + q^{3N+2}[N][N-1]T^4 \}
\]

– in full accordance with the results of [43].

**6.5.3 One more initial coloring: the 2-component whitehea link $\mathcal{R}_1 \mathcal{R}_2^{-1} \mathcal{R}_1 \mathcal{R}_2^{-1} \mathcal{R}_1$ (the L5a1 of [79] or 5$_2$ of [43])**

Now the braid becomes

\[
\bullet \quad \bullet \quad \bullet \quad \circ \quad \circ
\]

and the primary polynomial changes for

\[
q^{2-2N} \cdot (qT)^2 + [N-1].
\]
\[ q^{2-2N} \cdot (qT)^2 + [N-1] \cdot \]

\[
\begin{array}{c|ccc}
[N-1] & \times & \times & 2q^2 & q^3 \\
[N-2] & \times & \times & q^2 \\
[N-1] & \times & \times & 1 & 2q & q^2 \\
[N-2] & \times & \times & \frac{1}{q} \\
q^{-N} & \times & 1 & q & q^2 & 0 & q^2 & q^3 \\
\end{array}
\]

Applying four standard substitutions,
\[ [N-1](q^2 \Rightarrow q^3) \] by \( q^{4-N} \Rightarrow q^{N+1} \),
\[ q^2[N-2] \Rightarrow q^2[N-1] \] by \( 0 \Rightarrow q^N \),
\[ [N-1](1 \Rightarrow 2q \Rightarrow q^2) \] by \( q^{2-N} \Rightarrow q^{N-1} + q^{3-N} \Rightarrow q^N \)
and \( \frac{1}{q}[N-1] \Rightarrow \frac{1}{q}[N-2] \) by \( q^{1-N} \Rightarrow 0 \), we convert this into
\[ q^{2-2N} \cdot (qT)^2 + [N-1] \cdot \]

\[
\begin{array}{c|ccc}
q^N & \times & \times & \frac{1}{q} & 2 & q \\
q^{-N} & \times & 1 & 2q & 2q^2 & q^3 & q^2 + q^4 & q^3 \\
\end{array}
\]

\[
\sim q^{2-N}[N-1] \cdot (qT)^2 + (6.123)
\]

The underlined items in the first of these tables form two cohomologically trivial parts and are eliminated. In the second table we eliminated the \([N-1]\) factor – just one (boxed) term remains, which is taken away from the table – and inserted the \( q^{2-2N} \cdot (qT)^2 \) term inside the table, where it is underlined and can be eliminated together with another underlined term in the last line.

In result we get:
\[
\mathcal{P}^{5,1}_T = \frac{q^{3(N-1)}}{(qNT)^2} \left( q^{2-N}[N-1] \cdot (qT)^2 + q^{2-2N} + \frac{1}{q}(qT)^2 + (qT)^2 + q \cdot (qT)^3 + (q^2 + q^{2N-2})(qT)^4 + q^{2N-1}(qT)^5 \right) =
\]
\[
= \frac{1}{q^{N+1}T^2} + \frac{q^{N-3}}{T} + \left( q[N-1] + q^{N-1} \right) + q^{N+1}T + \left( q^{N+3} + q^{3N-1} \right)T^2 + q^{1N+1}T^3
\]  

(6.124)

In unreduced case we have instead of (6.123):
\[ q^{2-2N} \underbrace{[N]}_{\frac{1}{q}[N-1]+q^{N-1}} \cdot (qT)^2 + [N][N-1] \cdot \]

\[
\begin{array}{c|ccc}
q^N & \times & \times & \frac{1}{q} & 2 & q \\
q^{-N} & \times & 1 & 2q & 2q^2 & q^3 & q^2 + q^4 & q^3 \\
\end{array}
\]
\[
\sim q^{2-N}[N][N-1] \cdot (qT)^2 + [N-1] \cdot \left( q^2 + q^2 \right) + q^{1-N} \cdot (qT)^2
\]

| \( q^{2N} \times \) | \( q \times \) | \( q^2 \times \) |
|-----------------|-----------------|-----------------|
| \( q \)         | \( 1 \)         | \( 1 \)         |
| \( q^2 \)       |                 |                 |
| \( q^{2N} \times \) |               |                 |

where the usual shifts of powers occur in the second table, because we now eliminate the factor \([N]\) rather than \([N-1]\). Another difference is that the term \(q^{2-2N}[N](qT)^2\) can not be directly inserted inside the table, because the table remains multiplied by \([N-1]\). Thus \([N]\) in this term should be split in two pieces: one, proportional to \([N-1]\) is inserted and enters a cohomologically trivial pair (underlined), which can be eliminated, the second piece remains and will be later absorbed in inverse transformation of \([N-1]\) into \([N]\) in one of the terms in the answer. Keeping all this in mind, we obtain:

\[
\mathcal{P}^{5^2} = \frac{q^{3(N-1)}}{(q^N T)^2} \left\{ q^{2-N}[N][N-1] \cdot (qT)^2 + \left( q^{1-2N} + (qT) + q \cdot (qT)^2 + (qT)^3 \right) \right\} [N-1] + q^{1-N} \cdot (qT)^2 = \left( q[N-1] + q^{N-1} \right)[N] + \left\{ \frac{1}{q^{N+2}T^2} + \frac{q^{N-2}}{T} + q^NT + \left( q^{N+2} + q^{3N} \right) T^2 + q^{3N+2}T^3 \right\} [N-1] \quad (6.125)
\]

Expressions (6.124) and (6.125) coincide with the answers from [43].

### 6.6 Six intersections

#### 6.6.1 The knot \( R_1^3 R_2 R_1 R_2 \) (the torus \([2,5]\) or \(5_1\))

The KR complex for the braid is

\[
v_{00} \xrightarrow{d_0} 6v_{10} \xrightarrow{d_1} 7v_{20} + 8v_{21} \xrightarrow{d_2} 4v_{30} + 16v_{31} \xrightarrow{d_3} v_{40} + 11v_{41} + 3v_{42} \xrightarrow{d_4} 3v_{51} + 3v_{52} \xrightarrow{d_5} v_{62} \quad (6.126)
\]
and the primary polynomial:

\[ q^{6-6N} \cdot P^{5_1}_{r} = q^{2-2N} + [N - 1] \cdot \]

|          | \( q^4 \) | 3\( q^3 \) | \( q^2 \) | \( q^3 \) |
|----------|----------|----------|----------|----------|
| \([N - 1] \times [N - 2] \times\) |           |          |          |          |
| \([N - 1] \times [N - 2] \times\) | 4\( q^3 \) | 14\( q^2 \) | 12\( q \) | 2         |
| \([N - 1] \times [N - 2] \times\) | 7\( q^2 \) | 24\( q \) | 28 \( q^2 \) | 12 \( q \) | \( \frac{1}{q} \) |
| \([N - 1] \times [N - 2] \times\) | \( q^2 \) | 6\( q \) | 15 \( q^2 \) | \( \frac{12}{q} \) | \( \frac{3}{q^3} \) | \( \frac{1}{q^2} \) |
| \( q^{-N} \times 2q^2 \) 6\( q \) | 7         | \( \frac{4}{q} \) | \( \frac{1}{q} \) |
| \( q^{-N} \times 7q^2 \) 8\( q \) | 3         |
| \( q^{-N} \times 4q^3 \) 3\( q^2 \) |
| \( q^{-N} \times q^4 \) |

\[ \sim q^{2-2N} + [N - 1] \cdot \]

|          | \( \frac{1}{q} \) | \( q^3 \) | \( \frac{1}{q} \) | \( q^3 \) |
|----------|----------|----------|----------|----------|
| \([N - 1] \times [N - 2] \times\) |           |          |          |          |
| \( q^{-N} \times 0 \) 0 | 2\( q^2 \) | \( q^3 \) | \( q^4 \) |
| \( q^{-N} \times 0 \) 0 | \( q^2 \) | \( q^3 \) | \( q^4 \) | \( q^5 \) | 0 |

Thus we arrive at pattern (6.105), characteristic for 2-strand knots and links \([2, n]\) – this time with \( n = 5 \), i.e. we obtain the KR polynomial for the knot \( 5_1 = [2, 5] \):

\[ P^5_{r_1} = q^{4N-4} \left( 1 + \frac{q^4 T^2 + q^{2N+2} T^3 + q^8 T^4}{q^3} + \frac{q^{2N+6} T^5}{q^5} \right) \]

\[ P^5_{r_1} = q^{4N-4} \left( [N] + \left( q^3 T^2 + \frac{q^7 T^4}{q^3} \right)(1 + q^{2NT} [N - 1]) \right) \]  

(6.128)

Just the same hypercube describes a whole set of knots, associated with different colorings of the same knot diagram – at hypercube level this corresponds to different choices of initial vertex, leading to different KR complexes: the differentials are made from morphisms, which point away from the initial vertex. In the particular example, considered in this subsection, the hypercube has \( 2^5 = 64 \) vertices, and the set of emerging
knots includes:

| Name | $w$ | Braid word               |
|------|-----|--------------------------|
| $6_2$ | 2   | $[1, 1, -2, 1, -2]$       |
| $5_2$ | 4   | $[1, 1, 1, -1, 2]$        |
| $5_1$ | 6   | $[1, 1, 1, 2, 1, 2]$      |
| $4_1$ | 0   | $[1, -1, -1, 2, -1, 2]$   |
| $3_1$ | 4   | $[1, 1, 1, 2, 1, -2]$     |
|      | 2   | $[1, 1, 1, -2, 1, 2]$     |
|      | $-4$ | $[1, -1, -1, -2, -1, 2]$  |
| unknot | 0   | $[1, 1, -2, -1, 2]$       |
|      | 2   | $[1, 1, -2, -1, 2]$       |
|      | $-2$ | $[1, -1, -1, -2, -1, 2]$  |

Since simpler knots have already appeared in our considerations and their evaluation would just once again validate the topological invariance of our construction from [1], we now analyze only the new cases of $5_2$ and $6_2$.

6.6.2 Another initial vertex: the knot $R_1^3 R_2 R_1^{-1} R_2$ (the twisted knot $5_2$)

The KR complex for $\bullet \bullet \bullet \circ \bullet$ is

$v_{10} \overset{d_0}{\rightarrow} v_0 + 3v_{20} + 2v_{21} \overset{d_1}{\rightarrow} 5v_{10} + 3v_{30} + 7v_{31} \overset{d_2}{\rightarrow} 4v_{20} + 6v_{21} + v_{40} + 6v_{41} + 3v_{42} \overset{d_3}{\rightarrow} v_{30} + 9v_{31} + 2v_{50} + 3v_{51} \overset{d_4}{\rightarrow} 5v_{41} + v_{62} \overset{d_5}{\rightarrow} v_{51}$

The primary polynomial is obtained by reordering the columns in (6.127):

$$\left( \frac{q^{5N-5}}{q^{N}} \right)^{-1} \Psi_{5_2} = q^{2-2N} \cdot (qT) +$$
Outside the table are the values of the same items in unreduced case (when, of course, the extra factors \([N]\) and \([N - 1]\) are present – but suppressed in this formula).
Therefore

\[ P_{r}^{52} = \frac{q^{5N-5}}{q^{N}T} \left( q^{2-2N}(qT) + q^{3-2N}(qT)^2 + (1 + q^{4-2N})(qT)^3 + q \cdot (qT)^4 + q^2(qT)^5 + q^{2N-1}(qT)^6 \right) = \]

\[ = q^{2N-2} \left( 1 + q^2T + (q^4 + q^{2N})T^2 + q^{2N+2}T^3 + q^{2N+4}T^4 + q^{4N+2}T^5 \right) = q^{2N}T + (1 + q^{2N}T^2) \cdot P_{r}^{31}, \]

\[ P^{52} = q^{2N-2}[N] + \left( q^{2N-1}T + (q^{2N+1} + q^{4N-1})T^2 + q^{4N+1}(T^3 + T^4) + q^{6N+1}T^5 \right)[N - 1] \quad (6.129) \]

– in accordance with [43] ( unreduced polynomial was found there for \( N = 2, 3, 4 \)).

6.6.3 One more initial vertex: \( R_{i}^{3}R_{2}^{-1}R_{1}R_{2}^{-1} \) \( ( \text{the knot } 6_{2} ) \)

The KR complex for \( \bullet \quad \bullet \quad \bullet \quad \bullet \quad \) \( \bigcirc \quad \bigcirc \)

\( v_{20} \ x_{1} \ y_{2} \ x_{3} \ y_{4} \ x_{5} \ y_{6} \ x_{7} \ y_{8} \ x_{9} \ y_{10} \ x_{11} \ y_{12} \)

The primary polynomial:

\[
\begin{array}{ccc|c}
[N - 1] & \times & q^4 & (1) \\
[N - 1] & \times & 6q^3 & 3q^2 & (-3) \\
[N - 1] & \times & q^3 & 15q^2 & 14q & 3 & (3 = 4 - 1) \\
[N - 2] & \times & & & & & (1) \\
[N - 1] & \times & 4q^2 & 22q & 24 & \frac{10}{q} & \frac{1}{q^3} & (-3) \\
[N - 1] & \times & q^2 & 6q & 17 & \frac{18}{q} & \frac{9}{q^2} & \frac{2}{q^3} & (1) \\
[N - 1] & \times & 1 & \frac{4}{q} & \frac{3}{q^2} & \frac{1}{q^3} & (1) \\
[N - 2] & \times & \frac{3}{q} & \frac{3}{q^2} & \frac{1}{q^3} & (1) \\
q^{-N} & \times & 1 & 2q & 2q^2 & (1) \\
q^{-N} & \times & 4q & 6 & \frac{4}{q} & \frac{1}{q^3} & (-1) \\
q^{-N} & \times & q^2 & 6q^2 & 8q & 3 & (1 + 1) \\
q^{-N} & \times & 4q^3 & 3q^2 & (-1) \\
q^{-N} & \times & q^4 & (1) 
\end{array}
\]
Leaving only the underlined items in the upper part of the table, we can substitute it by

\[
\begin{array}{c|cccccc}
[N-1] \times & 0 & 0 & 1 & 3q & 4q^2 & 3q^3 & q^4 \\
[N-2] \times & q^3 + \frac{1}{q^3} & q^3 + \frac{1}{q^3} & \\
q^{-N} \times & 1 & q & 2q^2 & 0 & 0 & 0 & 0 \\
q^{-N} \times & 0 & 0 & 0 & q & q^2 & q^3 & q^4
\end{array}
\]

\[\sim q^{2-2N} \cdot (qT)^2 + [N-1].\]

\[
\begin{array}{c|cccc}
q^N \times & \frac{1}{q} & 2 & 2q & q^2 \\
q^{-N} \times & q^2 & 2q^3 & 2q^4 & q^5 \\
q^{-N} \times & \frac{1}{q} + q^5 \\
q^{-N} \times & 1 & q & 2q^2 & 0 & 0 & 0 \\
q^{-N} \times & 0 & 0 & 0 & q & q^2 & q^3 & q^4
\end{array}
\]

\[\sim q^{2-2N} \cdot (qT)^2 + [N-1].\]

\[
\begin{array}{c|cccc}
q^N \times & 0 & 0 & 0 & q^{-1} & 2 & 2q & q^2 \\
q^{-N} \times & 1 & q & 2q^2 & \frac{1}{q} + q^3 & 0 & 0 & 0
\end{array}
\]

At the last stage we absorbed the item from outside the table (underlined), and it makes a cohomologically trivial pair with another underlined item – and they both can be eliminated. From this we read:

\[
\mathcal{P}_{r^2}^{63} = \frac{q^{2N-4}}{T^2} \left( q^{2-2N} + \frac{1}{q} (qT) + (1 + q^{4-2N}) (qT)^2 + 2q (qT)^3 + (q^{2N-2} + q^2) (qT)^4 + (q^{2N-1} + q^3) (qT)^5 + q^{2N} (qT)^6 \right) = \\
= \frac{1}{q^2 T^2} + \frac{q^{2N-4}}{T} + (q^2 + q^{2N-2}) + 2q^{2N} T + (q^{4N-2} + q^{2N+2}) T^2 + (q^{4N} + q^{2N+4}) T^3 + q^{4N+2} T^4
\]

which coincides with the answer from [43] (up to a misprint in the underbraced term).

In unreduced case the two last tables are

\[
\begin{array}{c|cccc}
q^N \times & 0 & 0 & 0 & q^{-1} & 2 & 2q & q^2 \\
q^{-N} \times & 1 & q & 2q^2 & \frac{1}{q} + q^3 & 0 & 0 & 0
\end{array}
\]
The primary polynomial: \[ q^{2N} \times 0 \ 0 \ 0 \ 0 \ q^{-1} \ 1 \ q \]
\[ 1 \times 0 \ 0 \ 0 \ 1 \ q \ q^2 \]
\[ 1 \times 0 \ 1 \ q \ q^2 \]
\[ q^{-2N} \times q \ 0 \ q^3 + q \ 1 \ 0 \ 0 \ 0 \]

where in the item outside the table we substituted \([N] = \frac{1}{q}[N - 1] + q^{N-1}\), absorbed the first piece inside the table from where it can be eliminated together with another underlined term. Thus

\[ P^{62} = q^{N-1} + \]
\[ \frac{q^{2N-4}}{T^2} [N - 1] (q^{1-2N} + (qT) + (q + q^{3-2N})(qT)^2 + q[2](qT)^3 + (q^{2N-1} + q)(qT)^4 + (q^2 + q^2)(qT)^5 + q^{2N+1}(qT)^6) = \]
\[ q^{N-1} + [N - 1] \left( \frac{1}{q}T^2 + \frac{q^{2N-3}}{T} + (q^{2N-1} + q) + q^2[2]T + (q^4N-1 + q^{2N+1})T^2 + (q^{3N+1} + q^{2N+3})T^3 + q^{4N+3}T^4 \right) \]

again in accordance with [43] (where it was calculated for \(N = 2, 3, 4\)).

### 6.6.4 The braid \( \mathcal{R}_x^{62} \mathcal{R}_x^{62} \mathcal{R}_1^{2} \) (the knot \( 5_1 \))

The KR complex for

\[ \bullet \bullet \bullet \bullet \]

is

\[ v_{990} \overset{d_0}{\rightarrow} 6v_{10} \overset{d_1}{\rightarrow} 6v_{20} + 9v_{21} \overset{d_2}{\rightarrow} 2v_{30} + 18v_{31} \overset{d_3}{\rightarrow} 11v_{41} + 4v_{42} \overset{d_4}{\rightarrow} 2v_{51} + 4v_{52} \overset{d_5}{\rightarrow} v_{62} \quad (6.132) \]

The primary polynomial:

\[ q^{6-6N} \varphi_x = q^{2-2N} + [N - 1] \cdot \]

\[ [N - 1] \times \quad q^2 \quad 6q \quad 6q[2] + 9 \quad 2q[2]^2 + 18[2] \quad 11[2]^2 + 4 \quad 2[2]^3 + 4[2] \quad [2]^2 \]
\[ [N - 2] \times \quad 4[2] \quad 4[2]^2 \quad [2]^3 \]
\[ q^{-N} \times \quad 2q^2 \quad 6q \quad 6q[2] \quad 2q[2]^2 \]

\[ = q^{2-2N} + [N - 1] \cdot \]

\[ [N - 1] \times \quad 2q^3 \quad q^2 \quad (-1) \]
\[ [N - 1] \times \quad 2q^3 \quad 11q^2 \quad 10q \quad 2 \quad (1) \]
\[ [N - 1] \times \quad 6q^2 \quad 22q \quad 2q^{-1} \quad q^{-2} \quad (1) \]
\[ [N - 1] \times \quad q^2 \quad 6q \quad 15 \quad 20q^{-1} \quad 11q^{-2} \quad 2q^{-3} \quad (-1) \]
\[ [N - 2] \times \quad q^3 \quad (1) \]
\[ [N - 2] \times \quad 4q^2 \quad 3q \quad (-1) \]
\[ [N - 2] \times \quad 4q^2 \quad 8 \cdot q \quad 3q^{-1} \quad (-1) \]
\[ [N - 2] \times \quad 4q^{-1} \quad 4q^{-2} \quad q^{-3} \quad (1) \]
\[ q^{-N} \times \quad 2q^2 \quad 6q \quad 6q[2] \quad 2q[2]^2 \]
The primary polynomial: 

\[ q^{2-2N} + q^{-N}[N - 1]. \]

It is easy to recognize the familiar structure (6.105) – thus we indeed deal with the torus knot \([2, 5]\), alternatively named \(5_1\). The final step – elimination of the factor \([N - 1]\), it is slightly different in reduced and unreduced cases, and

\[
P^{5_1}_{r} = q^{6N-6}\left(q^{2-2N} + \frac{q^{4-2N}(qT)^2}{q} + q \cdot (qT)^3 + q^{6-2N}(qT)^4 + q^3 \cdot (qT)^5\right) = \]

\[
= q^{4N-4}\left(1 + q^4T^2 + q^{2N+2}T^3 + q^4T^4 + q^{2N+6}T^5\right). \quad (6.133)
\]

\[
P^{5_1} = q^{6N-6}\left\{q^{2-2N}[N] + (q^{3-2N}(qT)^2 + q^2 \cdot (qT)^3 + q^{5-2N}(qT)^4 + q^4 \cdot (qT)^5)[N - 1]\right\} = \]

\[
= q^{4N-4}\left\{[N] + (q^3T^2 + q^{2N+3}T^3 + q^7T^4 + q^{2N+7}T^5)[N - 1]\right\} = q^{4N-4}\left\{[N] + q^3T^2(1 + q^4T^2)(1 + q^2N)(N - 1)\right\}
\]

6.6.5 Another initial vertex: the braid \(R_1^2 R_2^{-1} R_1 R_2^{-2}\) (the knot \(6_3\))

The KR complex for \(\bullet \bullet \bullet \) is

\[
v_{30} \xrightarrow{d_6} 3v_{20} + 3v_{41} \xrightarrow{d_1} 3v_{10} + 9v_{31} + v_{31} + 2v_{52} \xrightarrow{d_2} v_{00} + 9v_{21} + 5v_{41} + 4v_{42} + v_{62} \xrightarrow{d_3} 3v_{10} + 9v_{31} + v_{51} + 2v_{52} \xrightarrow{d_4} 3v_{20} + 3v_{41} \xrightarrow{d_5} v_{30}
\]

The primary polynomial:

\[
\left(\frac{q^{3N-3}}{q^{3NT^3}}\right)^{-1} \cdot P^{6_3} = q^{2-2N}(qT)^3 + [N - 1].
\]

| \([N - 1] \times\) | \(q[2]^2\) | \(3q[2] + 3[2]^2\) | \(3q + 9[2] + [2]^3 + 2[2]\) | \(q^2 + 9 + 5[2]^2 + 4 + [2]^2\) | \(3q + 9[2] + [2]^3 + 2[2]\) | \(3q[2] + 3[2]^2\) | \(q[2]^2\) |
|---|---|---|---|---|---|---|---|
| \([N - 2] \times\) | \(2[2]^2\) | \(4[2] + [2]^3\) | \(2[2]^2\) |
| \(q^{-N} \times\) | \(q[2]^2\) | \(3q[2]\) | \(3q\) | \(2q^2\) | \(3q\) | \(3q^2\) | \(q[2]^2\) |

Rewriting the table in a more convenient form, we get:
As usual cohomologically non-trivial part of Ψ is concentrated around inverse diagonal – in underlined terms. In order to match two of the four underlined terms in the \([N-2]\) lines, we need to add an extra pair in the \([N-1]\) lines as well.

After that the upper part of the table is reduced and we obtain:

\[
\sim q^{2-2N} \cdot (qT)^3 + [N-1] \cdot
\]

\[
\begin{array}{c|cccccc}
[N-1] \times & 0 & 0 & q^{-1} & 3 & 4q & 3q^2 & q^3 \\
[N-2] \times & q^{-2} & q^{-1} + q & q^2 & q^{-2} & q^{-1} + q & q^2 \\
q^{-N} \times & q^{-1} & 1 & q & q^2 & 0 & q^2 & q^3 \\
\end{array}
\]
Reducing now the \([N-1]\) and \([N-2]\) factors inside the table, we get:

\[
q^{2-2N} \cdot (qT)^3 + [N-1] \cdot \begin{array}{c|cccc}
q^N & 0 & 0 & 0 & q^{-2} \  
q^{-N} & 0 & 0 & q & 2q^2 \ 
q^{-N} & 0 & 1 & [2]q^2 & q^4 \ 
q^{-N} & q^{-1} & 1 & q & q^2 \end{array}
\]

Collecting all the terms, proportional to \(q^{-N}\),

\[
\left(q^{-1} \ 2 \ \ 3q + q^3 \ 3q^2 + q^4 \ 2q^3 \ 2q^2 \ q^3\right) \sim \left(q^{-1} \ 2 \ \ 3q \ \ 2q^2 \ \ 0 \ \ 0 \ \ 0\right)
\]

we get:

\[
\left(\frac{q^{3N-3}}{(q^{3N}T)^3}\right)^{-1} \cdot \mathcal{P}_r^{63} \sim q^{2-2N} \cdot (qT)^3 + [N-1] \cdot \begin{array}{c|cccc}
q^N & 0 & 0 & 0 & q^{-2} \  
q^{-N} & 0 & 0 & q & 2q^2 \ 
q^{-N} & 0 & 1 & [2]q^2 & q^4 \ 
q^{-N} & 0 & q^{-1} & 1 & q \end{array}
\]

In reduced case this is cohomologically equivalent to

\[
\begin{array}{c|cccc}
q^{2N} & 0 & 0 & 0 & 0 \  
1 & 0 & 0 & 0 & 1 \ 
q^{-2} & 0 & q & q^2 \ 
q^{-2N} & q & q^2 & 2q^3 & q^2
\end{array}
\]

The second underlined term in the last line comes from the item outside the table and is eliminated together with another underlined term, so that

\[
\mathcal{P}_r^{63} = \frac{1}{q^{3T^3}} \left(q^{1-2N} + (q^{2-2N}+q^{-2})(qT) + (q^{3-2N}+q^{-1})(qT)^2 + 3(qT)^3 + (q^{3N-3}+q)(qT)^4 + (q^{2N-2}+q^2)(qT)^5 + q^{2N-1}(qT)^6\right) = \\
= \frac{1}{q^{2N+2T}T^3} + 3 + q^{2N+2}T^3 + (q^{N-2} + q^{2-N}) \left(\frac{1}{q^{N+2T^2}} + \frac{1}{q^N} + q^N T + q^{N+2}T^2\right) \quad (6.134)
\]
In unreduced case we have instead

\[
\left( \frac{q^{3N-3}}{q^{3N}T^3} \right)^{-1} \cdot \mathcal{P}^{63} \sim q^{2-2N}[N](qT)^3 + [N][N-1] \cdot q^N \times 0 0 0 q^{-2} 2q^{-1} 2q
\]

\[
q^{-N} \times q^{-1} 2 3q 2q^2 0 0 0
\]

\[
q^{2N} \times 0 0 0 0 q^{-2} q^{-1} 1
\]

\[
1 \times 0 0 0 q^{-1} 1 q
\]

\[
1 \times 0 q^{-1} 1 2q
\]

\[
q^{-2N} \times 1 q 2q^2 q
\]

and

\[
\mathcal{P}^{63} = q^{1-N} + \frac{[N-1]}{q^{3T}} \left( q^{-2N} + (q^{1-2N} + q^{-1})(qT) + (q^{2-2N} + 1)(qT)^2 + (2q + q^{-1})(qT)^3 + (q^{2N-2} + 1)(qT)^4 + (q^{2N-1} + q)(qT)^5 + q^{2N}(qT)^6 \right) = [N] + [N-1] \left( \frac{1}{q^{2N+3}T^3} + [2] + q^{2N+3}T^3 \right) + (q^{N-1} + q^{-1-N}) \left( \frac{1}{q^{N+2}T^2} + \frac{1}{q^{N}T} + q^{N}T + q^{N+2}T^2 \right) = [N] + [N-1] \left( \frac{1}{q^{2N+3}T^3} + [2] + q^{2N+3}T^3 \right) + [2N-2] \left( \frac{1}{q^{N+2}T^2} + \frac{1}{q^{N}T} + q^{N}T + q^{N+2}T^2 \right) \quad (6.135)
\]

Both (6.134) and (6.135) coincide with the answers from [43] (available only for \(N = 2\) and \(N = 3\) in unreduced case).

### 6.6.6 The 3-component link \(\mathcal{R}_2^2\mathcal{R}_2\) (torus link [3, 3] or \(6_3^1(v1)\) of [43])

The KR complex for the braid

\[
\bullet \bullet \bullet \bullet \bullet
\]

is

\[
v_{00} \xrightarrow{d_0} 6v_{10} \xrightarrow{d_1} 7v_{20} + 8v_{21} \xrightarrow{d_2} 4v_{30} + 16v_{31} \xrightarrow{d_3} v_{40} + 10v_{41} + 4v_{42} \xrightarrow{d_4} 2v_{51} + 4v_{52} \xrightarrow{d_5} v_{62} \quad (6.136)
\]

It differs from (6.126) only by the coefficients in the underlined terms – but now this is a 3-component link and the KR polynomial will be essentially different.
The primary polynomial is
\[ q^{6-6N} \cdot q_{r_{\gamma}}^{6\gamma(1)} = \]
\[
\begin{array}{|c|cccccccc|}
\hline
\times & q^2 & 6q & 7q[2] + 8 & 4q[2]^2 + 16[2] & q[2]^3 + 10[2]^2 + 4 & 2[2]^3 + 4[2] & [2]^2 \\
\hline
[N - 1] & q^2 & 6q & 7q[2] & 4q[2]^2 & q[2]^3 \\
[N - 2] & & & 4[2] & 4[2]^2 & [2]^3 \\
q^{-N} & 2q^2 & 6q & 7q[2] & 4q[2]^2 & q[2]^3 \\
\hline
\end{array}
\]

\[ = q^{2-2N} + [N - 1] \cdot \]

Note that, in variance from (6.50) which describes the same torus link \([3, 3]\), this time the space \(v_{51}\) is involved, still its contribution to the very first line of above table belongs to cohomologically trivial combination, and the main contribution comes from the underlined term in the second line, which is proportional to \([N - 1][N - 2]\), rather than to \([N - 1]^2\).

All the rest is already rather standard. The underlined pairs in the upper part of the table are of the type \([N - 1] \Rightarrow [N - 2]\) and get substituted by \(q^{2-N} \Rightarrow 0\), thus at the next stage we obtain

\[ q^{2-2N} + q^3[N - 1][N - 2](qT)^6 + q^{-N}[N - 1] \cdot \]

where the first line comes from the lower part of the previous table, while the second line – from reduction of pairs in its upper part. Underlined and overlined are the two pairs, which look cohomologically trivial – however, we know well, that the right answers require that something remains in the order \(T^3\) (this is not so difficult to see from analysis of morphisms – at level \(T^3\) their cohomologies are still rather simple to study explicitly). If we leave the overlined pair intact and eliminate only the underlined one, then the right answer emerges:

\[ q^{-N}[N-1] \cdot 0 \ 0 \ q^2 \ q^3 \ q^2 + 2q^4 \ 0 \ 0 \sim q^{-N}(q^2+2q^4)[N-1](qT)^4+q^{-N}\left(q^2\cdot q^2+q^3\cdot q^2\cdot (qT)^3\right) \]

(6.137)
in reduced case,

\[ q^{-N}[N-1][N] \begin{bmatrix} 0 & 0 & q^2 & q^3 & q^2 + 2q^3 & 0 & 0 \end{bmatrix} \sim q^{-N}(q^2 + 2q^4)[N-1][N][qT] + q^{-N}\left(q^2 - q^{-N}[qT]^2 + q^3 - q^{-N}[qT]^3\right)[N-1] \]

in unreduced case, and

\[
\mathcal{P}_r^{63}(v1) = q^{6N-6}\left(q^{2-2N} + q^{-2N}(qT)^2 + q \cdot (qT)^3\right) + q^{-N}(q^2 + 2q^4)[N-1](qT)^2 + q^3[N-1][N-2](qT)^6 = \\
q^{4N-4}\left(1 + q^4T^2 + q^{2N+2}T^3 + (q^{2N+4} + q^{2N+6})[N-1]T^4 + q^{2N+7}[N-1][N-2]T^6\right) \quad (6.138)
\]

\[
\mathcal{P}_3^{63}(v1) = q^{4N-4}\left([N] + q^4T^2(1 + q^{2N}T)[N-1] + (q^{2N+4} + q^{2N+6})[N][N-1]T^4 + q^{2N+7}[N][N-1][N-2]T^6\right)
\]

in agreement with (6.50) and [43] (for \(N = 2, 3\)).

6.6.7 Another coloring: the 3-component link \(\left(\mathcal{R}_1^2 \mathcal{R}_2^{-1}\right)^2\) \((6^3(2)\) of [43])

The KR complex for the braid \(\bullet \bullet \bullet \circ \circ \) is obtained by reordering of (6.136):

\[ 
v_{20} \xrightarrow{d_0} 2v_{10} + 4v_{31} \xrightarrow{d_1} v_{00} + 8v_{21} + 2v_{41} + 4v_{42} \xrightarrow{d_2} 4v_{10} + 12v_{31} + 4v_{52} \xrightarrow{d_3} 6v_{20} + 8v_{41} + 4v_{62} \xrightarrow{d_4} 4v_{30} + 2v_{51} \xrightarrow{d_5} v_{40} \]

80
The primary polynomial is
\[
q^{4-2N}T^2 \cdot \Psi_T^{6^2(\nu^2)} = q^{2-2N} \cdot (qT)^2 + [N - 1].
\]

| $[N - 1] \times$ | $q[2]$ | $2q + 4[2]$ | $q^2 + 8 + 2[2]^2 + 4$ | $4q + 12[2] + 4[2]$ | $6q[2] + 8[2]^2 + [2]^2$ | $4q[2]^2 + 2[2]^3$ | $q[2]^3$ |
|-----------------|--------|-------------|------------------|-----------------|-----------------|-----------------|--------|
| $[N - 2] \times$ | $4[2]$ | $4[2]^2$ | $[2]^3$ | | | | |
| $q^{-N} \times$ | $q[2]$ | $2q$ | $2q^2$ | $4q$ | $6q[2]$ | $4q[2]^2$ | $q[2]^3$ |

\[
= q^{2-2N} \cdot (qT)^2 + [N - 1].
\]

\[
\sim q^{2-2N}(qT)^2 + [N - 1].
\]

| $[N - 1] \times$ | $q^4$ | $q^3$ | $q^2$ | $q$ | $1$ | $1$ | $1$ |
|-----------------|------|------|------|----|----|----|----|
| $[N - 2] \times$ | $6q^3$ | $3q^2$ | $3q$ | $q$ | $1$ | $1$ | $1$ |
| $[N - 2] \times$ | $15q^2$ | $14q$ | $3$ | $q$ | $1$ | $1$ | $1$ |
| $[N - 2] \times$ | $3q^2$ | $20q$ | $24$ | $10q^{-1}$ | $q^{-2}$ | $1$ | $1$ |
| $[N - 2] \times$ | $6q^2$ | $16$ | $10q^{-1}$ | $9q^{-2}$ | $2q^{-3}$ | $1$ | $1$ |
| $[N - 2] \times$ | $1$ | $4q^{-1}$ | $2q^{-2}$ | $1$ | $1$ | $1$ | $1$ |

The last one is the minimal version of reduction – only the "must" items are kept (and selected from the usual places along the diagonals). However, the right answer requires to keep a couple of the seemingly trivial pairs
in the $[N-2]$ lines, we put them in additional line:

$$\sim q^{2-2N}(qT)^2 + [N-1].$$

|       | $[N-1] \times$ | $[N-2] \times$ | $q^{-N} \times$ |
|-------|----------------|----------------|----------------|
| $[N-1] \times$ | $0$ | $q^{-1}$ | $2$ | $q$ | $2q$ | $4q^2$ | $3q^3$ | $q^4$ |
| $[N-2] \times$ | $0$ | $0$ | $q^{-1}$ | $1$ | $q^2$ | $q^3$ | $0$ | $0$ |
| $[N-2] \times$ | $0$ | $0$ | $q$ | $1$ | $q^2$ | $q$ | $0$ | $0$ |
| $q^{-N} \times$ | $1$ | $q$ | $q^2$ | $q^2$ | $q^3$ | $q^4$ |

$$= q^{2-2N}(qT)^2 + [N-1].$$

|       | $[N-1] \times$ | $[N-2] \times$ | $q^{-N} \times$ |
|-------|----------------|----------------|----------------|
| $[N-1] \times$ | $0$ | $q^{-1}$ | $2$ | $q$ | $2q$ | $4q^2$ | $3q^3$ | $q^4$ |
| $[N-2] \times$ | $0$ | $0$ | $q^{-1} + q$ | $2 + 2q^2$ | $q + q^3$ | $0$ | $0$ |
| $q^{-N} \times$ | $1$ | $q$ | $q^2$ | $q^2$ | $q^3$ | $q^4$ |

$$\sim q^{2-2N}(qT)^2 + q[N-1][N-2](qT)^4 + [N-1].$$

|       | $[N-1] \times$ | $[N-2] \times$ | $q^{-N} \times$ |
|-------|----------------|----------------|----------------|
| $[N-1] \times$ | $0$ | $0$ | $0$ | $q$ | $2q^2$ | $2q^3$ | $q^4$ |
| $q^N \times$ | $q^{-1}$ | $2$ | $q$ |
| $q^{-N} \times$ | $q$ | $2q^2$ |
| $q^{-N} \times$ | $1$ | $q$ | $q^2$ | $q^2$ | $q^3$ | $q^4$ |

$$\sim q^{2-2N}(qT)^2 + q[N-1][N-2](qT)^4 + [N-1].$$

|       | $[N-1] \times$ | $[N-2] \times$ | $q^{-N} \times$ |
|-------|----------------|----------------|----------------|
| $q^N \times$ | $0$ | $0$ | $0$ | $1$ | $q$ | $q^2$ |
| $q^{-N} \times$ | $q^3$ | $q^4$ | $q^5$ |
| $q^-N \times$ | $1$ | $q$ | $q^2$ | $q^2$ | $q^3$ | $q^4$ |
| $q^N \times$ | $q^{-1}$ | $2$ | $q$ |
| $q^{-N} \times$ | $q$ | $2q^2$ |

Now, we eliminate the underlined items as belonging to cohomologically trivial pairs, take the boxed items outside the table and perform the usual reduction of the $[N-1]$ factor:
\[
\sim q^{2-2N}(qT)^2 + q[N - 1][N - 2](qT)^4 + 2q^{2-N}[N - 1](qT)^2 + q^{2+N}[N - 1](qT)^6 + [N - 1].
\]

\[
\begin{array}{c|cccc}
q^N & 0 & 0 & 0 & q^{-1} & 3 & 2q & 0 \\
q^{-N} & 1 & 2q & q^2 & 0 & 0 & 0 & 0 \\
\end{array}
\]

(6.139)

\[
\sim q[N - 1][N - 2](qT)^4 + 2q^{2-N}[N - 1](qT)^2 + q^{2+N}[N - 1](qT)^6 + [N - 1].
\]

\[
\begin{array}{c|cccc}
q^{2N} & 0 & 0 & 0 & q^{-2} & 2q^{-1} & 0 \\
1 & 0 & 0 & q & 2q^2 & 0 & 0 \\
1 & 0 & q^{-1} & 1 & 0 & 0 & 0 & 0 \\
q^{-2N} & q^2 & q & 0 & 0 & 0 & 0 \\
\end{array}
\]

(6.140)

where the first item is moved from outside to inside the table (underlined) and is eliminated together with another underlined term. In result the reduced KR polynomial is

\[
\frac{\mathcal{P}(v^2)}{p_T} = \frac{q^{2N-2}}{(qT)^2} \left( q^{2-2N} + q^{-1}(qT) + \left( 1 + 2q^{2-N}[N - 1] \right)(qT)^2 + q \cdot (qT)^3 + \right) \left( q^{2N-2} + 2q^2 + [N - 1][N - 2] \right)(qT)^4 + 2q^{2N-1}(qT)^5 + q^{2+N}[N - 1](qT)^6 = \]

\[
= \frac{1}{q^2T^2} + \frac{q^{2N-4}}{T} + \left( q^{2N-2} + 2q^N[N - 1] \right) + q^{2N}T + \left( q^{4N-2} + 2q^{2N+2} + q^{2N+1}[N - 1][N - 2] \right)T^2 + 2q^{4NT^3} + q^{3N+4}[N - 1]T^4
\]

(6.141)

This answer is in nice accordance with the result of [43]:

\[
N = 2 : \quad \frac{1}{q^{2T^2}} + \frac{1}{T} + 3q^2 + q^4T + 3q^6T^2 + 2q^8T^3 + q^{10}T^4,
\]

\[
N = 3 : \quad \frac{1}{q^{2T^2}} + \frac{1}{T} + (2q^2 + 3q^4) + q^6T + (q^6 + 3q^8 + q^{10})T^2 + 2q^{12}T^3 + q^{13}2T^4
\]

In unreduced case the difference appears in transition from (6.139) to (6.140):

\[
\sim q^{2-2N} [N] (qT)^2 + q[N][N - 1][N - 2](qT)^4 + 2q^{2-N}[N][N - 1](qT)^2 + q^{2+N}[N][N - 1](qT)^4 + \frac{1}{4}[N][N - 1] \cdot \]

\[
\begin{array}{c|cccc}
q^N & 0 & 0 & 0 & q^{-1} & 3 & 2q & 0 \\
q^{-N} & 1 & 2q & q^2 & 0 & 0 & 0 & 0 \\
\end{array}
\]

(6.142)

\[
\sim q[N][N - 1][N - 2](qT)^4 + 2q^{2-N}[N][N - 1](qT)^2 + q^{2+N}[N][N - 1](qT)^4 + [N - 1].
\]

\[
\begin{array}{c|cccc}
q^{2N} & 0 & 0 & 0 & q^{-1} & 2 & 0 \\
1 & 0 & 0 & 1 & 2q & 0 & 0 \\
1 & 0 & 1 & q & 0 & 0 & 0 \\
q^{-2N} & q & q^2 & q & 0 & 0 & 0 \\
\end{array}
\]

(6.143)
so that

\[
P_r^{6_2} = \frac{q^{2N-2}}{(qT)^2} [N - 1]\left\{ q^{1-2N} + (qT) + \left( q + 2q^{2-N}[N] \right)(qT)^2 + (qT)^3 + \right.
\]
\[
+ \left( q^{2N-1} + 2q + q[N][N-2] \right)(qT)^4 + 2q^{2N}(qT)^5 + q^{2N}[N][qT]^6 \right\} + \frac{q^{N-1}}{T} = \left( \frac{1}{q^{2N-3}} + \frac{q^{2N-3}}{T} \right)[N - 1] + \left(q^{2N-2}[N] + 2q^{N}[N][N-1] \right) + q^{2N-1}[N - 1]T + \]
\[
+ \left( q^{4N-1} + 2q^{2N+1} \right)[N - 1] + q^{2N+1}[N][N-1][N-2] \right)T^2 + 2q^{4N+1} [N - 1]T^3 + q^{3N+4}[N][N - 1]T^4. \tag{6.144}
\]

(the two underlined terms at the l.h.s. combine to form the underlined item at the r.h.s.). This answer coincides with that of [43] for \( N = 2 \) and \( N = 3 \).

### 6.6.8 The 2-component link 6\(_2\) \((L6\alpha 2)\) in the 3-strand representation

With the braid \( R_1^4R_2^3R_2^2R_2 \):

\[
\bullet \bullet \bullet \bullet \bullet \bullet \bullet \]

one associates a KR complex

\[
v_{00} \rightarrow 9v_{10} \rightarrow 18v_{20} + 18v_{21} \rightarrow 21v_{30} + 63v_{31} \rightarrow 15v_{40} + 95v_{41} + 16v_{42} \rightarrow \]
\[
\rightarrow 6v_{50} + 80v_{51} + 40v_{52} \rightarrow v_{60} + 39v_{61} + 44v_{62} \rightarrow 10v_{71} + 26v_{72} \rightarrow v_{81} + 8v_{82} \rightarrow v_{92}. \tag{6.145}
\]

This 2-component link has a very simple Jones polynomial \( q^7 + q^{11} \), still it is a really 9-intersection link \( 9_3^2 = L9n15 \).

However, the change of coloring to the braid \( R_1^4R_2^{-2}R_2^3R_2 \):

\[
\bullet \bullet \bullet \bullet \bullet \bullet \circ \circ \bullet \bullet \bullet \bullet \bullet \bullet \]

provides a 6-intersection 2-component link 6\(_2^3\). Associated with this braid is the KR complex

\[
v_{20} \rightarrow 2v_{10} + v_{30} + 6v_{31} \rightarrow v_{00} + 2v_{20} + 12v_{21} + 6v_{41} + 15v_{42} \rightarrow \]
\[
\rightarrow 7v_{10} + 42v_{31} + 27v_{51} + 8v_{52} \rightarrow 15v_{20} + 6v_{21} + 16v_{41} + 19v_{61} + 16v_{62} \rightarrow \]
\[
\rightarrow 20v_{30} + 15v_{31} + 38v_{51} + 32v_{52} + 7v_{71} + 14v_{72} \rightarrow 15v_{40} + 20v_{41} + 14v_{61} + 28v_{62} + v_{81} + 6v_{82} \rightarrow \]
\[
\rightarrow 6v_{50} + 15v_{51} + 2v_{71} + 12v_{72} + v_{92} \rightarrow v_{00} + 6v_{61} + 2v_{82} \rightarrow v_{71}. \tag{6.146}
\]

Reduced primary polynomial in this case is:

\[
\left( q^{2N-7} \right)^{-1} P_r^{6_2} = q^{2-2N}(qT)^2 + [N - 1].
\]

| \( q^{-N} \) | 1 | \( (qT) \) | \( (qT)^2 \) | \( (qT)^3 \) | \( (qT)^4 \) |
|---|---|---|---|---|---|
| \( q \) | \( q[2] \) | \( 2q + q[2]^2 + 6[2] \) | \( q^2 + 2q[2] + 12 + 21[2]^2 \) | \( 7q + 42[2] + 27[2]^3 + 8[2] \) | \( 15q[2] + 6 + 54[2]^2 + 16 + 19[2]^4 + 16[2]^2 \) |
| \( [N-1] \times \) | \( q[2] \) | \( 2q + q[2]^2 \) | \( 2q^2 + 2q[2] \) | \( 7q \) | \( 15q[2] \) |
| \( [N-2] \times \) | \( q[2] \) | \( 20q[2]^2 + 15[2] + 38[2]^3 + 32[2]^3 + 7[2]^3 + 14[2]^3 \) | \( 15q[2]^3 + 20[2]^2 + 14[2]^2 + 28[2]^3 + 6[2]^6 + 6[2]^4 \) | \( 6q[2]^4 + 15[2]^3 + 2[2]^5 + 12[2]^3 + [2]^5 \) | \( q[2]^5 + 6[2]^4 + 2[2]^4 \) |
| \( [N-1] \times \) | \( 32[2]^2 + 14[2]^4 \) | \( 28[2]^2 + 6[2]^5 \) | \( 12[2]^4 + [2]^6 \) | \( 2[2]^5 \) | \( q[2]^5 \) |
Now, before drawing and manipulating entire tables we calculate the generating function of alternated sums:

\[ u(q) = q[2] - q \cdot (2q + q[2]^2 + 6[2]) + \ldots = q^3 - q^6 + q^4 - 2q^2 + 1 \]  (6.147)

the entry in column \( k = 0, \ldots, 9 \) is taken with the weights \((-q)^k\). The answer is a polynomial \( \sum_i m_i q^i \) and its coefficients \( m_i \) are exactly the alternated sums in the \( [N - 1] \) lines, presented in the last column of the detailed table below (the smaller \( i \) the lower is the line). Similarly for the \( [N - 2] \) lines:

\[ v(q) = -q^3 \cdot 8[2]^3 + q^4 \cdot (16[2] + 16[2]^3) - \ldots = q^{13} - 2q^{11} + q^9 - q^5 + 2q^3 - q \]  (6.148)

and for the \( q^{-N} \) lines:

\[ w(q) = q[2] - q \cdot (2q + q[2]^2) + \ldots = q^{14} - q^{12} + q^{10} - q^8 + q^6 + q^4 - q^2 \]  (6.149)

The linear combination

\[ q^{7-2}(u(q) + q^{-2}w(q) + q^{-2} \cdot q^2) \]

gives the Jones polynomial, while

\[ \frac{A^{7-2}}{q^2} \left( u(q) \frac{A/q}{\{q\}} + v(q) \frac{A/q}{\{q\}} + w(q)A^{-1} \right) \frac{A/q}{\{q\}} + \frac{A^{5-2}}{q^5} \]

is the HOMFLY polynomial.

The detailed table looks like

| \( q^{-N} \times \) | \( q^{-N} \times \) | \( q^{-N} \times \) | \( q^{-N} \times \) | \( q^{-N} \times \) | \( q^{-N} \times \) | \( q^{-N} \times \) | \( q^{-N} \times \) | \( q^{-N} \times \) |
|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| \( q^2 \times \) | \( q^3 \times \) | \( 4q^2 \times \) | \( \frac{2}{q} \times \) | \( 7q \times \) | \( \frac{5q^2}{q} \times \) | \( q^6 \times \) | \( \frac{6q^5}{q} \times \) | \( \frac{15q^4}{q} \times \) |
| \( q^2 \times \) | \( q \times \) | \( \frac{1}{q} \times \) | \( q^3 \times \) | \( q^4 \times \) | \( q^5 \times \) | \( q^6 \times \) | \( q^7 \times \) | \( q^8 \times \) |
| \( q^2 \times \) | \( q^3 \times \) | \( 4q^2 \times \) | \( \frac{2}{q} \times \) | \( 7q \times \) | \( \frac{5q^2}{q} \times \) | \( q^6 \times \) | \( \frac{6q^5}{q} \times \) | \( \frac{15q^4}{q} \times \) |
| \( q^2 \times \) | \( q \times \) | \( \frac{1}{q} \times \) | \( q^3 \times \) | \( q^4 \times \) | \( q^5 \times \) | \( q^6 \times \) | \( q^7 \times \) | \( q^8 \times \) |
| \( q^2 \times \) | \( q^3 \times \) | \( 4q^2 \times \) | \( \frac{2}{q} \times \) | \( 7q \times \) | \( \frac{5q^2}{q} \times \) | \( q^6 \times \) | \( \frac{6q^5}{q} \times \) | \( \frac{15q^4}{q} \times \) |
| \( q^2 \times \) | \( q \times \) | \( \frac{1}{q} \times \) | \( q^3 \times \) | \( q^4 \times \) | \( q^5 \times \) | \( q^6 \times \) | \( q^7 \times \) | \( q^8 \times \) |

85
Picking up the underlined items from the table, we get:

\[
\begin{array}{c|cccccccc}
[N-1] \times & 0 & 0 & q^{-2} & 2q^{-1} & q & q^2 & 0 & 0 & 0 \\
[N-2] \times & 0 & 0 & 0 & q^{-2} & 2q^{-1} & q^3 & 2q^4 & q^5 & 0 \\
q^{-N} \times & 0 & q & q^2 & 0 & q^2 & q^3 & q^4 & q^5 & q^6 \\
\end{array}
\]

\[
\begin{array}{c|cccccccc}
1 \times & 0 & 0 & 0 & 0 & q^{3-N} & q^N & 0 & 0 & 0 \\
1 \times & 0 & 0 & 0 & 0 & 0 & 0 & q^{6-N} & q^{N+1} & q^{7-N} & q^{N+2} & 0 \\
q^{-N} \times & 0 & q & 1 + q^2 & 2q & 2q^2 & q^3 & q^4 & q^5 & q^6 & 0 \\
\end{array}
\]

\[
\begin{array}{c|cccccccc}
q^N \times & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & q & q^2 & 0 \\
q^{-N} \times & 0 & 0 & 0 & q & 2q^2 & 2q^3 & q^4 & q^5 & q^6 & 0 \\
\end{array}
\]

Now it remains to multiply by \([N-1]\) and further reduce the lines, except for the boxed element. Then we get

\[
\left( \frac{q^{7-N-7}}{(q^N T)^2} \right)^{-1} \mathbb{P}_r^{62} \sim q^{2-2N} (qT)^2 + [N-1] q^{2-2N} (qT)^2 + q^{N+2}[N-1](qT)^8 + 0 0 0 0 q^{3-2N} + q^{4-2N} 1 + q^{4-2N} q + q^{5-2N} q^2 + q^2 0 q^{2N-1} 0 0 \]

(6.150)

so that

\[
T_r^{62} = q^{3N-3} \left( 1 + q^2 T + (q^2 + q^4) T^2 + (q^2 N^2 + q^6) T^3 + 2 q^{2N+2} T^4 + q^{A+2} T^5 + q^{3N+6}[N-1]T^6 \right) \]

(6.151)

In unreduced case modified is just the last step: instead of (6.150),

\[
\left( \frac{q^{7-N-7}}{(q^N T)^2} \right)^{-1} \mathbb{P}_r^{62} \sim q^{2-2N} (qT)^2[N] + [N][N-1] q^{2-2N} (qT)^2[N] + q^{N+2}[N-1](qT)^8 + [N-1] q^{2-2N} q + q^{3-2N} q^2 + q^{4-2N} q + q^3 q^{2N} 0 0
\]
so that
\[ P^{62}_N = q^{3N-3} \left( [N] + q[N-1]T + (q^{2N+1} + q^3)[N-1]T^2 + (q^{2N+3} + q^5)[N-1]T^3 + \right. \\
\left. + q^{2N+4}[2][N-1]T^4 + q^{4N+3}[N-1]T^5 + q^{3N+6}[N][N-1]T^6 \right) \]  
(6.152)

These results are in accord with [43] (note that there is no orientation dependence for 6\(^2\)_2 and both versions of [43] are in fact equivalent – related by the usual change \( q, t \rightarrow q^{-1}, t^{-1} \)).

7 4-strand examples

7.1 Decomposition of \( \mathcal{R} \)-matrices

A product of the fundamental representations decomposes with the help of the representation tree [58]:

\[
\begin{array}{c}
\vdots \\
| \\
| \\
[1] \\
| \\
\downarrow \\
2 \\
| \\
\downarrow \\
\downarrow \\
\downarrow \\
[3] \\
| \\
\downarrow \\
\downarrow \\
[4] \\
| \\
\downarrow \\
[21] \\
| \\
\downarrow \\
[21] \\
| \\
\downarrow \\
[11] \\
\end{array}
\]

2-strand case:
In the beginning of this paper, we decomposed the \( \mathcal{R} \) matrix, acting in the space \([1] \otimes [1] = [2] + [11] \) as
\[
\mathcal{R} \sim q^{-1}P_{[2]} - qP_{[11]} \sim I - q[2]P_{11} 
\]  
(7.1)
and associated \( I \) with the black and \( P_{11} \) with the white points in the hypercube vertices. Then the contribution of \( n \) white points,
\[
v_n = \frac{1}{[N]} \text{Tr}_q \left( [2]P_{11} \right)^n = \frac{[2]^n D_{11}}{[N]} = [2]^{n-1} [N-1] 
\]  
(7.2)
was identified with the dimension of the vector space at the corresponding hypercube vertex.

3-strand case:
In this case we have two \( \mathcal{R} \) matrices, acting on the first two and on the last two of representations in the product \([1] \otimes [1] \otimes [1] \). They related by the mixing (Racah) matrix [58]:
\[
\mathcal{R}_2 = U \mathcal{R}_1 U^\dagger 
\]  
(7.3)

From the look at representation tree it is clear that the decomposition (7.1) implies that
\[
\mathcal{R}_1 \sim I - q[2](P_{[21]} + P_{[111]}) = I - q[2]\pi_1 
\]  
(7.4)

Therefore
\[
\mathcal{R}_2 = I - q[2]\pi_2, \quad \pi_2 = U\pi_1 U^\dagger, \quad U = \begin{pmatrix} c & s \\ -s & c \end{pmatrix} = \begin{pmatrix} \frac{1}{\sqrt{2}} & \frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{2} & \frac{1}{\sqrt{2}} \end{pmatrix} 
\]  
(7.5)
and the quantities of interest are now
\[ v_{n,k} = [2]_n^n \cdot \frac{1}{[N]} \text{Tr}_q \left( \pi_1 \pi_2 \right)^k = [2]^n \frac{D_{111} + c^{2k} D_{21}}{[N]} = [2]^{n-1}[N-1] \frac{[N-2] + [2]^{1-2k}[N+1]}{[3]} \quad (7.6) \]
where \( c = [2]^{-1} \) is the non-trivial diagonal element of the mixing matrix in the [21] sector, it appears because
\[
\begin{pmatrix}
0 & 0 & 1 \\
-1 & s & c \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
0 & 0 & 1 \\
0 & 0 & 1 \\
0 & 0 & 1
\end{pmatrix}
= \begin{pmatrix}
0 & 0 & 1 \\
0 & 0 & 1 \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
s^2 & cs & c^2 \\
0 & cs & c^2
\end{pmatrix}
\]
\[ \pi_1 \pi_2 \]
\( (7.7) \)

The crucial next feature was the fact that
\[ \frac{[N-2] + [2]^{1-2k}[N+1]}{[3]} = [2]^{1-2k}\left( [N-1] + [2][N-2] \sum_{i=0}^{k-2} [2]^i \right) \quad (7.8) \]
– this provided the formulas (6.9) that we used in the study of the 3-strand examples:
\[ v_{n,k} = [2]^{n-2k}[N-1] \left( [N-1] + [2][N-2] \sum_{i=0}^{k-2} [2]^i \right) \quad (7.9) \]

One can formulate the phenomenon is follows: after elimination of denominator ([3]) dimensions become bilinear combinations of \([N-1]\) and \([N-2]\) (in particular, \([N+1]\) disappeared). As usual, dependence on the total number \( n \) of white points is only in the overall factor \([2]^n\).

**4-strand case:**
This time there are three \( R \)-matrices and thus two types of mixing matrices
\[ R_2 = U_{21} R_{1} U_{21}^\dagger, \quad R_3 = U_{31} R_{1} U_{31}^\dagger, \quad (7.10) \]
explicitly evaluated in[8]. Now \( R_i \sim I - q[2] \pi_i \) where the 4-strand avatar of the projection operator \( P_{11} \) is now
\[ \pi_1 = P_{[3]1}^{\nu} + P_{[2]1}^{\nu} + P_{[11]1}^{\nu} + P_{[11]11}^{\nu}, \quad \pi_2 = U_{21} \pi_1 U_{21}^\dagger, \quad \pi_3 = U_{31} \pi_1 U_{31}^\dagger \quad (7.11) \]

According to [8] the mixing matrices are:
\[ U_{21} = \begin{pmatrix}
1 & 1 & c_2 & s_2 \\
0 & -s_2 & c_2 & 0 \\
0 & -s_2 & c_2 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}, \quad V = \begin{pmatrix}
1 & 1 & c_3 & s_3 \\
0 & -s_3 & c_3 & 0 \\
0 & -s_3 & c_3 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}, \quad U_{31} = U_{21} V U_{21} \quad (7.12) \]

where the five blocks correspond to the sectors \([4], [31], [22], [211] \) and \([1111] \) and the size of the block is the multiplicity with which this representation appears in the product \([1]^\otimes 4\). The cosines and sines of the mixing angles are
\[ c_k = \frac{1}{[k]}, \quad s_k = \sqrt{1 - c_k^2} = \sqrt{\frac{[k+1][k-1]}{[k]}}, \quad cc_2 = 2c_2^2 - 1 = -\frac{[4]}{[2]^3}, \quad ss_2 = -\sqrt{1 - cc_2^2} = -\frac{2\sqrt{3}}{[2]^2} \quad (7.13) \]

Since \( \pi_i^2 = \pi_i \), the dimensions \( v_{n,k} \) do not depend on powers of projectors - and thus are the same for many of hypercube vertices. They rather depend on the words, made from the letters \( k_i = 1, 2, 3 \) without repetitions:
\[ v_{n,k}^{(n)} = \frac{[2]_n^n}{[N]} \text{Tr}_q \left( \prod_i \pi_{k_i} \right) = [2]^n \text{Tr} \left( D \prod_i \pi_{k_i} \right) \quad (7.14) \]
where quantum trace is substituted by the ordinary trace with additionally inserted diagonal matrix of reduced quantum dimensions

\[ D = \text{diag} \left( \frac{D_1}{|N|}, \frac{D_{31}}{|N|}(1, 1, 1), \frac{D_{22}}{|N|}(1, 1, 1), \frac{D_{231}}{|N|}(1, 1, 1), \frac{D_{1111}}{|N|} \right) \]  (7.15)

As usual, the dependence on the number \( n \) of white points is in the simple common factor \([2]^n\).

The lowest examples are:

\[ v_0 = [N] \cdot v_{00} = [N]^3, \]

\[ v_n = [N] \cdot v_{n0} = [2]^{n-1}[N]^2[N - 1], \]

\[ v^{(n)}_{(12)} \cdot v^{(n)}_{(23)} = [N] \cdot v_{n,k} = [2]^{n-2k}[N][N - 1] \left( [N - 1] + [2][N - 2] \sum_{i=0}^{k-2} [2]^i \right), \]

\[ v^{(n)}_{(13)} = v^{(n)}_{13} = \frac{2^n}{|N|} D^{2}_{11} = [2]^{n-2}[N][N - 1]^2, \]

\[ v^{(n)}_{(123)} = \frac{[2]^{n-2}}{|N|} \left( [2^2 D_{1111} + q^2 D_{22} + 2q^2 D_{2111}] \right) = [2]^{n-3}[N - 1]^3, \]

\[ v^{(n)}_{123} = v^{(n)}_{123} = [2]^{n-3}[N - 1]^3, \]

\[ v^{(n)}_{(123)^2} = [2]^{n-5}[N - 1]^2 \left( [N - 1] + [2][N - 2] \right), \]

\[ v^{(n)}_{(123)^2} = [2]^{n-6}[N - 1] \left( [2][N - 1]^2 + 2[N - 1][N - 2] + [N - 2][N - 3] \right), \]

\[ v^{(n)}_{(123)^2} = [2]^{n-7}[N - 1] \left( [N - 1]^2 + 3[2][N - 1][N - 2] + [2][N - 2][N - 3] \right), \]

\[ \ldots \]  (7.16)

For one particular series of dimensions we have:

\[ v^{(n)}_{(123)} = [2]^{n-8}[N - 1] \left( [2][N - 1]^2 + 6[N - 1][N - 2] + (q^2 + 5 + q^{-2})[N - 2][N - 3] \right), \]

\[ v^{(n)}_{(123)} = [2]^{n-10}[N - 1] \left( [2][N - 1]^2 + 14[N - 1][N - 2] + (q^4 + 7q^2 + 19 + 7q^{-2} + q^{-4})[N - 2][N - 3] \right), \]

\[ v^{(n)}_{(123)} = [2]^{n-2k-2}[N - 1] \left( [2][N - 1]^2 + 2(2^{k-1} - 1)[N - 1][N - 2] + \xi_k[N - 2][N - 3] \right) \]  (7.17)

where the first several coefficients \( \xi_k \) are:

\[
\begin{align*}
  k & = 1 \quad \quad 0 \\
  k & = 2 \quad \quad 1 \\
  k & = 3 \quad \quad [3] + 4 \\
  k & = 4 \quad \quad [5] + 6[3] + 12 \\
  k & = 5 \quad \quad [7] + 8[5] + 25[3] + 33 \\
  k & = 6 \quad \quad [9] + 10[7] + 42[5] + 91[3] + 89 \\
  k & = 7 \quad \quad [11] + 12[9] + 63[7] + 185[5] + 313[3] + 243 \\
  \ldots
\end{align*}
\]  (7.18)

We see that like \( v^{(n)}_{n,k} \) in the 3-strand case were bilinear combinations of \([N - 1] \) and \([N - 2] \), these 4-strand space dimensions are trilinear combinations of \([N - 1], [N - 2], [N - 3] \). Some factors \([N] \) also appear when not all the four strands are involved into intersections – then we substitute them by \([N] = q[N - 1] + q^{1-N} \) – thus also some terms with \( q^{-N} \) factors appear. Note, that there is no need to reduce them further to \([N - 2] \) or \([N - 3] \).
7.2 Separation of partly-sterile contributions

Primary polynomial in the 4-strand case is decomposed as

\[
q^{n_4(N-1)} \left( \frac{q^{n_4(N-1)}}{(q^N T)^{n_4}} \right)^{-1} \mathfrak{P}^L = q^{3-3N} + A[N-1]^3 + \frac{[N-1][N-2]}{2} \left( B[N-1] + C[N-3] \right)
\]

(7.19)

with \(N\)-independent polynomials \(A, B, C\), with integer coefficients. However, these coefficients are not obligatory positive and there is also a factor \(2\) in denominator in the last two terms. The same phenomenon was already present in the 3-strand case – and this what the origin of the \(q^{-N}\) lines in our tables. As we know from that experience, contributions to such lines arise from the factors \([N]\), which appear when some of the strands are "sterile" – not participate in any intersection. This means that such contributions (hypercube vertices) should be handled separately – and only the rest, i.e. really \(m = 4\)-strand contributions should be decomposed like in (7.19).

7.3 Unknot as a torus [4, 1]

For the KR complex

\[
v_0 \rightarrow \begin{array}{c} 3[N]v_{10} \\ v_{11} + v_{21} + v_{31} \\ v_{12} + v_{22} + v_{32} \end{array} \rightarrow v^{(3)}_{123}
\]

(7.20)

we have

\[
q^{3-3N} \mathfrak{P}^{[4,1]}_{r} = [N]^3 + 3[N]^2[N-1] \cdot (qT) + 3[N][N-1]^2 \cdot (qT)^2 + [N-1]^3 \cdot (qT)^3 = q^{3-3N} + [N-1] \left( q^3[N-1]^2(1+T)^3 + 3q^{3-N}[N-1](1+T)^2 + 3q^{3-2N}(1+T) \right)
\]

(7.21)

where we substituted \([N]\) by \(q[N-1]+q^{-1-N}\). Note that this was done in all the three partly-sterile contributions, which we put in the box (in this particular case the majority of spaces are boxed, but for complicated knots and links the majority will be non-sterolie). From this formula it is obvious that reduced and non-reduced KR polynomials are

\[
\mathfrak{P}^{[4,1]}_{r} = q^{3N-3} \cdot q^{3-3N} = 1, \quad \mathfrak{P}^{[4,1]} = [N]
\]

(7.22)

as they should be for the unknot.

If we did not handle the partly-sterile contributions separately, we would get decomposition (7.19) with

\[
qA = 3 + 3q^2 + q^4 + 3q^2[2]T + 3q^3[2]T^2 + q^4T^3 = (T+1)(q^4T^2 + 2q^4T + 3q^2T + q^4 + 3q^2 + 3),
\]

\[
qB = -3 \left( 2q^2[2]^2 + (2 + 3q^2 + 2q^4)T + q^3[2]T^2 \right) = -3(T+1)(q^3[2]T + [2]^2),
\]

\[
qC = 3q^2(T+1)
\]

(7.23)

These formulas are, of course, consistent with (7.21); they are obtained from it by the substitutions

\[
q^{2-N} = [N-1] - q[N-2],
\]

\[
q^{4-2N} = [N-1]^2 - \frac{q^2 + 2}{[2]}[N-1][N-2] + \frac{q^2}{[2]}[N-2][N-3]
\]

(7.24)

However, (7.23) is of little use for construction of KR polynomials – it is (7.21) that should be used.

7.4 The 2-component torus link \(T[4, 2]\) (the \(4^2_7\) link of [43])

First of all, with the 4-strand braid [4, 2]
we naturally associate the product

\[
\text{Tr} \left( (1 + \tau \pi_1)(1 + \tau \pi_2)(1 + \tau \pi_3)(1 + \tau \pi_1)(1 + \tau \pi_2)(1 + \tau \pi_3) \right) = \\
\text{Tr} \left( I + (6\tau + 3\tau^2 + \pi + (8\tau^2 + 8\tau^3)\pi_1\pi_2 + (4\tau^2 + 4\tau^3 + \tau^4)\pi_1\pi_3 + 4\tau^4(\pi_1\pi_2)^2 + \\
+ (8\tau^3 + 9\tau^4 + 2\tau^5)\pi_1\pi_2\pi_3 + \tau^4\pi_1\pi_2\pi_3\pi_2 + 4\tau^5(\pi_1\pi_2)^2\pi_3 + \tau^6(\pi_1\pi_2\pi_3)^2 \right)
\]

(7.25)

where symbol \( \text{Tr} \) implies the possibility of cyclic permutations in the product and identifications of, say, \( \pi_1 \pi_2 \) with \( \pi_2 \pi_3 \) (but not with \( \pi_1 \pi_3 \)) and we temporarily introduced a parameter \( \tau = q T[2] \). The first line at the r.h.s. contains partly-sterile items, which are actually 0, 1, 2, 3-strand expressions times powers of \([N]\), while the second line consists of the non-sterile, i.e. essentially 4-strand contributions, to be expanded into \( A, B, C \) polynomials.

Collecting terms with the same power of \( \tau \) we can read from this what the KR complex is:

\[
v_0 \rightarrow 6[N]v_{10} \rightarrow 3[N]v_{20} + 8[N]v_{21} + 4v_{21}^{(2)} \rightarrow 8[N]v_{31} + 4v_{13}^{(3)} + 8v_{123}^{(3)} \\
\rightarrow v_{13}^{(4)} + 2[N]v_{42} + 10v_{123}^{(4)} + 2v_{1232}^{(4)} \rightarrow 2v_{1232}^{(5)} + 4v_{123123}^{(5)} \rightarrow v_{123123}^{(6)}
\]

(7.26)

and the primary polynomial

\[
q^{6-6N} p_r^{(4,2)} = [N]^3 + 6[N]^2[N - 1](qT) + [N]\left(3[2][N][N - 1] + (8 + 4)[N - 1]^2 \right)(qT)^2 + \\
+ \left( (8 + 4)[2][N][N - 1]^2 + 8[N - 1]^3 \right)(qT)^3 + \\
+ \left( [N]\left(2[N - 1]^2 + 2[N - 1][N - 1] + 2[N - 1][N - 2] \right) \right)(qT)^4 + \\
+ \left( 2^2[N - 1]^3 + 4[N - 1]^2([N - 1] + 2[N - 2]) \right)(qT)^5 + \\
+ [N - 1]([2][N - 1]^2 + 2[N - 1][N - 2] + [N - 2][N - 3])(qT)^6
\]

(7.27)

Now, substituting \([N] = q[N - 1] + q^{-N}\) and re-expanding into \( A, B, C \) polynomials plus \( q^{-N} \) terms, we get:

\[
q^{6-6N} p_r^{(4,2)} = q^{3-3N} + q^{-2N}[N - 1] \left( 3q^3 + 6q^3T + 3q^4[2]T^2 \right) + q^{-N}[N - 1][N - 2] \cdot 2q^5[2]T^4 + \\
+ q^{-N}[N - 1]^2 \left( 3q^3 + 12q^3T + 6q^4[2]T^2 + 12q^3T^2 + 12q^4[2]T^3 + q^5([2]^2 + 2)T^4 \right) + \\
+ [N - 1]^3 \left( 3q^3 + 8q^3T + 3q^4[2]T^2 + 12q^3T^2 + q^5([2]^2 + 4)T^4 + \\
+ q^5([2]^2 + 2)T^4 + 12q^4[2]T^4 + q^5([2]^2 + 4)T^4 + [2][q^6T^6] \right) +
\]

(7.28)
From this we can now read our usual tables:

\[ q^{6-6N} \mathcal{P}^{[4,2]}_r = q^{3-3N} + [N - 1]. \]  

|       | 1 | \((qT)\) | \((qT)^2\) | \((qT)^3\) | \((qT)^4\) | \((qT)^5\) | \((qT)^6\) |
|-------|---|--------|--------|--------|--------|--------|--------|
| \([N - 1]^2 \times\) | \(3q^3\) | \(6q^2\) | \(3q^2[2] + 12q\) | \(12q[2] + 8\) | \(q([2]^2 + 2) + 12[2]\) | \([2][2]^2 + 4\) | \([2]\) |
| \([N - 1][N - 2] \times\) | \(2q[2]\) | \(8[2]\) | \(2\) |
| \([N - 2][N - 3] \times\) | \(1\) |
| \(q^{-N}[N - 1] \times\) | \(3q^3\) | \(12q^2\) | \(6q^2[2] + 12q\) | \(12q[2]\) | \(q([2]^2 + 2)\) |
| \(q^{-N}[N - 2] \times\) | \(2q[2]\) |
| \(q^{-2N} \times\) | \(3q^3\) | \(6q^2\) | \(3q^2[2]\) |

Now we could follow our standard procedure, but instead we prefer to abbreviate and formalize it.

8 Concise formulation of the procedure and more complicated examples

8.1 The algorithm

We are now ready to formulate the shortened sequence of steps for building up the KR polynomials. Within our mnemonic approach it does not actually require explicit construction of the hypercube (which would be necessary for explicit construction of morphisms): we can directly start from the spaces of KR complex and formulate mnemonic rules for construction of differentials – surprisingly or not, the rules appear very simple and arbitraryness, though persists, is satisfactorily low.

1) In \(m\)-strand case we calculate the primary polynomial \(\mathcal{P}^\ell = [N] \cdot \mathcal{P}^\ell_r\) by the standard technique of HOMFLY calculus, exhaustively described in [? 68, 69].

2) Decompose these primary polynomials as functions of \(N\):

\[
\mathcal{P}^\ell_r = \frac{q^{n\ast(N-1)}}{(q^N T)^{n_2}} \sum_{k=0}^{m-1} A^\ell_k(q, T) \cdot \left( q^{(k+1-m)N} \prod_{i=1}^{k} [N - i] \right),
\]

\[
\mathcal{P}^\ell = [N] \cdot \mathcal{P}^\ell_r = \frac{q^{n\ast(N-1)}}{(q^N T)^{n_2}} \sum_{k=0}^{m-1} A^\ell_k(q, T) \cdot \left( q^{(k+1-m)N} \prod_{i=0}^{k} [N - i] \right)
\]  

(8.1)

Emerging \(m\) functions \(A_0, \ldots, A_{m-1}\) no longer depend on \(N\) only on \(q\) and \(T\).

3) At \(T = -1\) the functions \(A_k\) for knots should be proportional to \(\{q\}^k = (q - q^{-1})^k\), while for \(l\)-component links – to \(A_{k_{\geq 1}} \sim \{q\}^{k_{1\leq 1}}\). As functions of \(T\) they should be cohomologically equivalent to multiples of \((1 + q^2T)^{k+1-l}\), i.e.

\[
A_k = (1 + q^2T)^{k+1-l} \tilde{A}_k + (1 + T) \times \text{positive polynomial}
\]  

(8.2)

4) Each of non-trivial functions \(A_1, \ldots, A_{l-1}\) is cohomologically equivalent to a combination of just a few "diagonal" functions:

\[
A_k(q, T) = \sum_{\{m_k\}} q^{m_k} T^{v_k} \left( 1 + q^2T + q^4T^2 + \ldots + (q^2T)^{v_k} \right) + (1 + T) \times \text{positive polynomial}
\]  

(8.3)
The choice of $\nu$ defines $\mu$ and $s$.

5) In most cases there is some finite freedom in selecting $\nu$ – and this is what is going to be fixed by the study of morphisms, beyond this paper. However, for relatively simple knots and links the choice is not too big and, most important, it does not depend on $N$ – this it can be easily fixed by comparison with existing knowledge, including the Jones-Khovanov polynomials for $N = 2$, available in [79].

6) Diagonal functions are further reduced with the help of identities like

$$[N - 1](1 + q^2T) = q^{2-N} + q^NT + q[N - 2](1 + T) \sim q^{2-N} + q^N T \quad (8.4)$$

and

$$[N][N - 1](1 + q^2T) = (q^{1-N} + q^{N+1}T)[N - 1] + q[N - 1]^2(1 + T) \sim q^{1-N} + q^{N+1}T \quad (8.5)$$

applied to reduced and unreduced polynomials respectively. When $s_k$ is odd, this is a uniquely defined procedure. For $s_k$ even one term remains unpaired and there is an additional freedom to choose which – say, at one or another end of the diagonal.

To handle $A_k$ with the property (8.2) one can need to apply (8.4) several times, e.g.

$$[N - 1][N - 2](1 + q^2T)^2 = (q^{2-N} + q^NT + q[N - 2](1 + T))\left( q^{3-N} + q^{N-1}T + q[N - 3](1 + T) \right) \sim \left( q^{2-N} + q^NT \right) \left( q^{3-N} + q^{N-1}T \right) = q^{5-2N} + q^2[2]T + q^{2N-1}T^2 \quad (8.6)$$

and

$$[N - 1][N - 2][N - 3](1 + q^2T)^3 \sim \left( q^{2-N} + q^NT \right) \left( q^{3-N} + q^{N-1}T \right) \left( q^{4-N} + q^{N-2}T \right) = q^{9-3N} + q^{5-N}[3]T + q^{N+1}[3]T^2 + q^{3N-3}T^3 \quad (8.7)$$

In unreduced case instead of (8.5) we have:

$$[N][N - 1][N - 2](1 + q^2T)^2 \sim \left( q^{1-N} - q^{N+1}T \right) \left( q^{3-N} + q^{N-1}T \right) [N - 1] = \left( q^{4-2N} + (q^4 + 1)T + q^{2N}T^2 \right) [N - 1] \quad (8.8)$$

and

$$[N][N - 1][N - 2][N - 3](1 + q^2T)^3 \sim \left( q^{1-N} + q^{N+1}T \right) \left( q^{3-N} + q^{N-1}T \right) \left( q^{4-N} + q^{N-2}T \right) [N - 1] = \left( q^{8-3N} + q^{-N}(q^8 + q^4 + q^2)T + q^N(q^4 + q^2 + q^{-2})T^2 + q^{4N-2}T^3 \right) [N - 1] \quad (8.9)$$

Note that reduction is only to $[N - 1]$, though in (8.8) it could be to $[N - 2]$ and in (8.9) – to $[N - 3]$, providing

$$\left( q^{1-N} - q^{N+1}T \right) \left( q^{2-N} + q^NT \right) [N - 2]$$

and

$$\left( q^{1-N} + q^{N+1}T \right) \left( q^{2-N} + q^NT \right) \left( q^{3-N} + q^{N-1}T \right) [N - 3]$$

respectively. This, however, would cause discrepancy from the answers of [43] and would thus correspond to some other choice of morphisms.

7) The remaining cohomologically non-trivial terms form the KR polynomial.

One can easily recognize these steps in our above examples – and we saw that they indeed can easily reproduce the known answers. In particular, this procedure does not necessarily eliminate everything, proportional to $T + 1$ – and here the role of diagonal functions seems important. Clearly this diagonal structure reflects some basic property of morphisms and it will be in the focus of further studies of this story.

Now we provide a few more complicated examples, which are technically difficult to handle without the concise formulation of the present section. In practice, we begin every example below from the list of possible diagonal functions for $A_0, \ldots, A_7$. Still, the knowledge of spaces, which form the KR complex, – which we overlook in such presentation – remains important for future discussion of morphisms, in this sense examples below lack certain information, which can still be relevant.
8.2 The 2-component torus link \([4, 2]\) revisited

In this case the concise procedure implies that we begin from eq.\((7.27)\). Still, making the story a little slower, we calculate the trace of a product of \(10 \times 10\) matrices,

\[
\mathfrak{p}_r^{[4, 2]} = q^{6N-6} \text{Tr}_{10 \times 10} \left\{ D(1 + \tau \pi_1)(1 + \tau \pi_2)(1 + \tau \pi_3)(1 + \tau \pi_1)(1 + \tau \pi_2)(1 + \tau \pi_3) \right\}
\]

with \(\tau = [2]qT\) and expand it according to \((8.1)\):

\[
q^{6-6N} \mathfrak{p}_r^{[4, 2]} = A_0q^{-3N} + A_1 \cdot q^{-2N}[N - 1] + A_2 \cdot q^{-N}[N - 1][N - 2] + A_3 \cdot [N - 1][N - 2][N - 3]
\]

This is an easy computation, because \(A_0\) is just the value of the trace at \(N = 1\), and after that \(A_1, A_2, A_3\) are extracted from its values at \(N = 2, 3, 4\). One easily checks in this way that \(A_2\) and \(A_3\) are proportional to \(T + 1\), and can be neglected in the further analysis. \(A_0\) is just a monomial (as usual),

\[
A_0^{[4, 2]} = q^3
\]

The only non-trivial piece is \(A_1\). We represent it as a table (keeping in mind more complicated examples, we change positions of lines and columns).

### Table of \(A_1^{[4, 2]}\)

|       | \(q^3\) | \(q^5\) | \(q^7\) | \(q^9\) | \(q^{11}\) |
|-------|---------|---------|---------|---------|----------|
| \(T\) | 1       |         |         |         |          |
| \(T^2\) | 3       | 6       | 12      | 6       |          |
| \(T^3\) | 3       | 21      | 21      | 3       |          |
| \(T^4\) | 1       | 17      | 17      | 1       |          |
| \(T^5\) | 2       | 8       | 2       |         |          |
| \(T^6\) |         |         |         | 1       | 1        |

\(\sim\) \(\sim\)

### Table of \(A_1^{[4, 2]}\) (8.13)

|       | \(q^3\) | \(q^5\) | \(q^7\) | \(q^9\) | \(q^{11}\) |
|-------|---------|---------|---------|---------|----------|
| \(T\) | 1       |         |         |         |          |
| \(T^2\) |         |         |         |         |          |
| \(T^3\) |         |         |         |         |          |
| \(T^4\) |         |         |         |         |          |
| \(T^5\) |         |         |         |         |          |
| \(T^6\) |         |         |         |         |          |

Alternative sums are now calculated along columns and, according to \((8.3)\) we should pick up one diagonals with three entries, marked by crosses. Clearly there are three possible choices, the right one turns out to be the middle, with crosses circled. Moreover, since there are three entries on this selected diagonal, only two of them can be reduced with the help of \((8.4)\) and \((8.5)\), and we should select the one, which remains intact – the right choice is boxed. These selections provide

\[
\mathfrak{p}_r^{[4, 2]} = q^{6N-6} \left( q^{3-3N} + q^{-2N} \cdot q^5T^2 \left( q^{2-N} + q^NT \right) q^9T^4q^{-2N}[N - 1] \right)
\]

\[
= q^{3-3N} \left( 1 + q^4T^2 + q^{2N+2}T^3 + q^{N+6}[N - 1]T^4 \right),
\]

\[
\mathfrak{p}_r^{[4, 2]} = q^{6N-6} \left( q^{3-3N}[N] + q^{-2N} \cdot q^5[N - 1]T^2 \left( q^{1-N} + q^N+1T \right) q^9T^4q^{-2N}[N][N - 1] \right)
\]

\[
= q^{3-3N} \left( [N] + q^3T^2(1 + q^2N)T[N - 1] + q^{N+6}[N][N - 1]T^4 \right) \quad \text{ (8.14)}
\]

– in accordance with \([43]\) and our 2- and 3-strand calculations in \((5.60)\) and \((6.104)\), \((6.120)\), \((6.121)\) respectively.

This confirms topological invariance of our procedure.
8.3 The 2-strand knots and links, once again

As a further demonstration of concise procedure, we once again consider the 2-strand case. Here

\[ q^{-n(N-1)} A_r^{[2,n]} = \text{Tr}_{2 \times 2} \left\{ D \cdot (I + \tau \pi)^n \right\} = q^{1-N} + \left( q + \sum_{k=1}^{n} [2]^{k-1} C_n^k (q T)^k \right) \] [8.15]

Then

| \( n \) | \( q \) | \( q^3 \) | \( q^5 \) | \( q^7 \) | \( \ldots \) | \( q^{2i-1} \) | \( \ldots \) | \( q^{2k-1} \) | \( \ldots \) | \( q^{2n-1} \) |
|---|---|---|---|---|---|---|---|---|---|---|
| 1 | 1 | \( T \) | \( n \) | \( T^2 \) | \( C_n^2 \) | \( C_n^2 \) | 2 \( C_n^3 \) | \( C_n^3 \) | \( C_n^4 \) | \( C_n^4 \) |
| 1 | \( n-1 \) | \( C_{n-1}^2 \) | \( C_{n-1}^3 \) | \( C_{n-1}^4 \) | \( \ldots \) | \( \ldots \) | \( \ldots \) | \( \ldots \) | \( 1 \) | [8.16]

In this case there is just one suitable diagonal, and the only arbitrariness is the choice of the boxed item for even \( n \) (for odd \( n \) the box should be removed):

\[ A_r^{[2,n]} \sim \]

| \( n \) | \( q \) | \( q^3 \) | \( q^5 \) | \( q^7 \) | \( \ldots \) | \( q^{2k-1} \) | \( \ldots \) | \( q^{2n-1} \) |
|---|---|---|---|---|---|---|---|---|
| 1 | \( \times \) | \( \times \) | \( \times \) | \( \times \) | \( \times \) | \( \times \) | [8.17]

Application of (8.4) and (8.5) converts this into the standard answers:

\[ r^{[2,n]} = q^{(n-1)(N-1)} \left( 1 + q^4 T^2 + q^{2N+2} T^3 + \ldots + q^{4i} T^{2i} + q^{2N+4i} T^{2i+1} + \ldots + q^{N+2n-2} [N-1] T^n \right) \]

if \( n \) is even

\[ r^{[2,n]} = q^{(n-1)(N-1)} \left\{ [N] + \left( q^3 T^2 + \ldots + q^{4i-i} T^{2i} + \ldots \right) (1 + q^{2N} T) [N-1] + q^{N+2n-2} [N] [N-1] T^n \right\} \]

if \( n \) is even

The last term is present only for even \( n \), i.e. for the 2-strand links.
8.4 3-strand torus knots and links

This time
\[ q^{−2n(N−1)} \Phi_{r}^{[3,n]} = \text{Tr}_{4\times4} \left\{ D \cdot (I + \tau \pi_1)(I + \tau \pi_2) \right\}^{n} = q^{2−2N} + A_{1}^{[3,n]} \cdot q^{-N}[N−1] + A_{2}^{[3,n]}[N−1][N−2] \]

The matrices are 4 × 4 and act as numbers on representations [3] and [111], while as 2 × 2 matrices on the space of two representations [21].

To understand the general structure it is enough to look at the first few examples.

8.4.1 \( n = 1 \) (unknot)
Both \( A_{2}^{[3,1]} \) and \( A_{1}^{[3,1]} \) are cohomologically trivial, thus
\[ \mathcal{P}_{r}^{[3,1]} = q^{2N−2} \cdot q^{2−2N} = 1, \]
\[ \mathcal{P}^{[3,1]} = q^{2N−2} \cdot q^{2−2N}[N] = [N] \] (8.19)

8.4.2 \( n = 2 \) (trefoil)
The function \( A_{2}^{[3,2]} = q^{3}(1 + T)(2q^{2}T^{2} + T^{2} + 2T + 1) \) is cohomologically trivial,

\[
A_{1}^{[3,2]} = \begin{pmatrix}
1 & 2 & 1 \\
T & 4 & 4 \\
T^{2} & 2 & 8 & 2 \\
T^{3} & 4 & 4 \\
T^{4} & & & & \\
(0) & (1) & & & \\
\end{pmatrix} \begin{pmatrix}
1 & & & & \\
T & & & & \\
T^{2} & & & & \\
T^{3} & & & & \\
T^{4} & & & & \\
(0) & (1) & & & \\
\end{pmatrix} \sim \begin{pmatrix}
q^{-2} & q^{-4} & q^{-6} \\
q^{2} & q^{4} & q^{6} \\
\end{pmatrix}
\] (8.20)

Then
\[ q^{4}T^{2}(1 + q^{2}T) \cdot q^{-N}[N−1] \begin{pmatrix}
q^{-2} & q^{-4} \\
q^{2} & q^{4} \\
\end{pmatrix} \sim q^{4}T^{2}(q^{2−N} + q^{N}T) \] (8.4)

in reduced, and
\[ q^{4}T^{2}(1 + q^{2}T) \cdot q^{-N}[N][N−1] \begin{pmatrix}
q^{-2} & q^{-4} \\
q^{2} & q^{4} \\
\end{pmatrix} \sim q^{4}T^{2}(q^{1−N} + q^{N+1}T)[N−1] \] (8.5)

in unreduced case, so that
\[
\mathcal{P}_{r}^{[3,2]} = q^{4N−4} \left( q^{2−2N} + q^{4−N}T^{2}(q^{2−N} + q^{N}T) \right) = q^{2N−2} \left( 1 + q^{4}T^{2} + q^{2N+2}T^{3} \right),
\]
\[
\mathcal{P}_{r}^{[3,2]} = q^{4N−4} \left( q^{2−2N}[N] + q^{4−N}T^{2}(q^{1−N} + q^{N+1}T)[N−1] \right) = q^{2N−2} \left( [N] + q^{3}T^{2}(1 + q^{2N}T)[N−1] \right) \] (8.21)
8.4.3 $n = 3$, a link

Since the link is 3-component, and $N^3 = N(N - 1)(N - 2) + 3N(N - 1) + N$, our functions $A_2$ and $A_3$ should contain at least one and three unbalanced cohomologically non-trivial terms. Indeed,

\[
A_2^{[3,3]} = \begin{array}{cccc} 
q^3 & q^5 & q^7 & q^9 \\
1 & 1 & 1 & 1 \\
T & 6 & 15 & 20 \\
T^2 & 15 & 6 & 22 \\
T^3 & 15 & 30 & 2 \\
T^4 & 6 & 18 & 9 \\
T^5 & 1 & 4 & 5 \\
T^6 & 1 & 4 & 5 & 1 \\
\end{array} \sim \begin{array}{cccc} 
q^3 & q^5 & q^7 & q^9 \\
1 & T & T^2 & T^2 \\
T & T^3 & T^3 & T^3 \\
T^2 & T^4 & T^4 & T^4 \\
T^3 & T^5 & T^5 & T^5 \\
T^4 & T^6 & T^6 & T^6 \\
\end{array}
\]

\[
A_1^{[3,3]} = \begin{array}{cccc} 
q^2 & q^4 & q^6 & q^8 \\
1 & 2 & 1 & 1 \\
T & 6 & 6 & 6 \\
T^2 & 6 & 21 & 6 \\
T^3 & 2 & 24 & 24 & 2 \\
T^4 & 9 & 24 & 9 & 2 \\
T^5 & 6 & 6 & 1 & 2 \\
T^6 & 1 & 4 & 5 & 1 \\
\end{array} \sim \begin{array}{cccc} 
q^2 & q^4 & q^6 & q^8 \\
1 & T & T^2 & T^2 \\
T & T^3 & T^3 & T^3 \\
T^2 & T^4 & T^4 & T^4 \\
T^3 & T^5 & T^5 & T^5 \\
T^4 & T^6 & T^6 & T^6 \\
\end{array}
\]

where we selected the items in $A_1$ at allowed (by the values of partial Euler characteristics) places on the main diagonal. This is not a minimal choice, but it satisfies three additional mnemonic rules: there are no gap along the diagonal there is a contribution in the $T^3$ line and contributions with additional factors $[N - 1]$ are concentrated in one power in $T$ (and with $[N - 1][N - 2]$ – in another power). Anyhow, this is the choice which leads to the right answer (and which should be justified by the future analysis of morphisms). The two un-boxed crosses are reduced by the rule (8.4) in reduced case:

\[
q^4T^2(1 + q^2T) \cdot q^{-N}[N - 1] \sim q^{4-N}T^2(q^{2-N} + q^N)T
\]

and by the rule (8.5) in unreduced case:

\[
q^4T^2(1 + q^2T) \cdot q^{-N}[N][N - 1] \sim q^{4-N}T^2(q^{1-N} + q^{N+1})[N - 1]
\]

so that

\[
P_r^{[3,3]} = q^{6N-6}(q^{2-2N} + q^{4-N}T^2(q^{2-N} + q^N)T + (q^4T^4 + 2q^8T^4)q^{-N} [N - 1] + q^2T^6[N - 1][N - 2] = q^{4N-4}(1 + q^4T^2 + q^{2N+2}T^3 + (q^{N+4} + 2q^{N+6})[N - 1]T^4 + q^{2N+7}[N - 1][N - 2]T^6)
\]

(8.24)

\[
P^{[3,3]} = q^{4N-4}([N] + q^3T^2(1 + q^{2N}T)[N - 1] + (q^{N+4} + 2q^{N+6})[N][N - 1]T^4 + q^{2N+7}[N][N - 1][N - 2]T^6)
\]

in agreement with (6.50) and [43]. (and also – in reduced case – with [50] and [56, 57]).

97
8.4.4  $n = 4$, a knot $8_{19}$

The function

$$A_2^{[3,4]} = \begin{array}{cccccccc}
q^3 & q^5 & q^7 & q^9 & q^{11} & q^{13} \\
1 & 1 & T & 8 & \hline
T^2 & 28 & 12 & \hline
T^3 & 56 & 64 & 8 & \hline
T^4 & 70 & 142 & 54 & 2 & \hline
T^5 & 56 & 168 & 128 & 16 & \hline
T^6 & 28 & 112 & 140 & 48 & \hline
T^7 & 8 & 40 & 8 & 72 & 48 & \hline
T^8 & 1 & 6 & 14 & 15 & 6 & 1 & \hline
\end{array}$$

and

$$A_1^{[3,4]} = \begin{array}{cccccccc}
q^2 & q^4 & q^6 & q^8 & q^{10} \\
1 & 2 & 1 & T & 8 & 8 & \hline
T^2 & 12 & 40 & 12 & \hline
T^3 & 8 & 72 & 72 & 8 & \hline
T^4 & 2 & 56 & 128 & 56 & 2 & \hline
T^5 & 16 & 88 & 88 & 16 & \hline
T^6 & 20 & 48 & 20 & \hline
T^7 & 8 & 8 & \hline
T^8 & 1 & \hline
\end{array}$$

contributes

$$q^9T^6(1 + q^2T^2)[N - 1][N - 2] \sim q^9T^6(q^{2-N} + q^N T)(q^{3-N} + q^{N-1}T)$$

to reduced polynomial. Similarly,

$$A_2^{[3,4]} = \begin{array}{cccccccc}
q^3 & q^5 & q^7 & q^9 & q^{11} & q^{13} \\
1 & 1 & T & 8 & \hline
T^2 & 28 & 12 & \hline
T^3 & 56 & 64 & 8 & \hline
T^4 & 70 & 142 & 54 & 2 & \hline
T^5 & 56 & 168 & 128 & 16 & \hline
T^6 & 28 & 112 & 140 & 48 & \hline
T^7 & 8 & 40 & 8 & 72 & 48 & \hline
T^8 & 1 & 6 & 14 & 15 & 6 & 1 & \hline
\end{array}$$

and

$$A_1^{[3,4]} = \begin{array}{cccccccc}
q^2 & q^4 & q^6 & q^8 & q^{10} \\
1 & 2 & 1 & T & 8 & 8 & \hline
T^2 & 12 & 40 & 12 & \hline
T^3 & 8 & 72 & 72 & 8 & \hline
T^4 & 2 & 56 & 128 & 56 & 2 & \hline
T^5 & 16 & 88 & 88 & 16 & \hline
T^6 & 20 & 48 & 20 & \hline
T^7 & 8 & 8 & \hline
T^8 & 1 & \hline
\end{array}$$

contributes

$$q^4T^2(1 + q^2T^2 + q^4T^2)(1 + q^2T) \cdot q^{-N}[N - 1] \sim q^{4-N}T^2(1 + q^2T^2 + q^4T^2)\left(q^{2-N} + q^N T\right)$$

Putting all together we get:

$$P_r^{[3,4]} = q^{8N-8} \left( q^{2-N} + q^{1-N}T^2(1 + q^3[2]T^2)\left(q^{2-N} + q^N T\right) + q^9T^6(q^{2-N} + q^N T)(q^{3-N} + q^{N-1}T) \right) =$$

$$= q^{8N-6} \left( 1 + q^4T^2 + q^{2N+2}T^3 + q^7[2]T^4 + q^{2N+4}[2]T^5 + q^{12}T^6 + q^{2N+8}[2]T^7 + q^{4N+6}T^8 \right)$$

(8.27)

in agreement with (6.73) and thus with [50] and [56].

In unreduced case we have instead

$$P_r^{[3,4]} = q^{8N-8} \left\{ q^{2-N}[N] + \left( q^{4-N}T^2(1 + q^3[2]T^2)(q^{1-N} + q^{N+1}T) + q^9T^6(q^{1-N} + q^{N+1}T)(q^{3-N} + q^{N-1}T) \right)[N - 1] \right\} =$$

98
This is different from our (6.77),

\[ q^{6N-6} \left\{ [N] + q^3[N-1]T^2 + q^{2N+3}[N-1]T^3 + [2]q^6[N-1]T^4 + [2]q^{2N+6}[N-1]T^5 + \\
+q^{10}[N-2]T^6 + [2]q^{2N+9}[N-2]T^7 + q^{4N+8}[N-2]T^8 \right\} \quad (8.29) \]

which, we think, is overreduced – down to \([N-2]\), while, as we suggest in the present section 8, the 3-strand knot should not be reduced more than to \([N-1]\). Another argument is that with the present prescription the case \(n = 4\) nicely suites into general formulas valid for all \(n\) – in the spirit of \([56]\) and \([73]\), and we avoid "accidental" cancelations, possible in this particular example. Still, rigorous way to choose between these possibilities requires the study of morphisms.

### 8.4.5 \(n = 5\), a knot 10_{124}

The knowledge of alternated sums in this case requires the reduction of the two functions to be

| \(q^3\) | \(q^5\) | \(q^7\) | \(q^9\) | \(q^{13}\) | \(q^{15}\) | \(q^{17}\) | \(q^2\) | \(q^4\) | \(q^6\) | \(q^8\) | \(q^{10}\) | \(q^{12}\) |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | \(T\) | \(T^2\) | \(T^3\) | \(T^4\) | \(T^5\) | \(T^6\) | \(T^7\) | \(T^8\) | \(T^9\) | \(T^{10}\) | \(0\) | \(0\) | \(0\) | \(1\) | \(-2\) | \(2\) | \(-2\) | \(1\) | \(0\) | \((0)\) | \(0\) | \(0\) | \((0)\) | \((-1)\) |

\[ A_2^{[3,5]} \sim \quad A_1^{[3,5]} \sim \]

what further implies

\[ q^{10(N-1)} \left( q^9T^6(1 + q^4T^2)(1 + q^2T)^2[N-1][N-2] + q^4T^2(1 + q^3[2]T^2 + q^6T^4)(1 + q^2T) \cdot q^{-N}[N-1] + q^{2-2N} \right) \]

\[ \sim \quad q^{8N-8} \left( 1 + q^{4N+2}T^2(1 + q^3[2]T^2 + q^6T^4)(q^{2-N} + q^N T) + q^{2N+7}T^6(1 + q^4T^2)(q^{2-N} + q^N T)(q^{3-N} + q^{N-1}T) \right) \]

Therefore

\[ P^{[3,5]} = q^{8N-8} \left( 1 + q^4T^2 + q^{2N+2}T^3 + q^7[2]T^4 + q^{2N+5}[2]T^5 + q^{11}[2]T^6 + \\
+ (2q^{2N+8} + q^{2N+10})T^7 + (q^{16} + q^{4N+6})T^8 + q^{2N+13}[2]T^9 + q^{4N+10}T^{10} \right) = \quad (8.30) \]

\[ = q^{8N-8} \left\{ 1 + q^4T^2 \left( 1 + q^3[2]T^2 + q^6T^4 \right)(1 + q^{2N-2}T) + q^{12T^6} \left( 1 + q^4T^2 \right)(1 + q^{2N-2}T)(1 + q^{2N-4}T) \} \]

and

\[ P^{[3,5]} = q^{8N-8} \left\{ [N] + \left( q^3T^2(1 + q^3[2]T^2 + q^6T^4) + q^{11}[2](1 + q^4T^2)(1 + q^{2N-4}T) \right)(1 + q^N T)[N-1] \right\} \quad (8.31) \]

These formulas are in accordance with (8.31), which is in turn consistent with \([56]\). – and with (6.91). Moreover, now we wrote them in the form, allowing generalization to arbitrary \(n\): it is clear that the only things that
depend on \( n \) are the two underlined functions – literally read from diagonals in the tables for \( A_2 \) and \( A_1 \).

Moreover, like in the first function, coming from \( A_1 \), the overall coefficient \( q^4 T^2 \) does not depend on \( n \), in the second function, coming from \( A_2 \), intact is the last coefficient: it depends on \( n \), but in an obvious way:

\[
q^3 (q^2 T)^{2n-3} = q^{4n-3} T^{2n}.
\]

8.4.6 \( n = 6 \), a 3-component link

Like for \([n, 3]\), there will be one and three non-compensated non-trivial contributions, proportional to \([N - 1][N - 2]\) and to \([N - 1]\) respectively, but this time they will be considerably more sophisticated. Moreover we will need to make two iterations to formulate what are the proper reductions of \( A_2 \) and \( A_1 \). Justification of these choices is provided by the answer from [56] – and by the general structure of the formulas for all \( n \) at once.

The structure of reduction is crucially restricted by the values of alternated sums in columns of our tables, i.e. by decomposition of Euler characteristic (HOMFLY polynomial):

\[
HOMFLY = q^{12N-12} \left( E_2(q) \cdot [N - 1][N - 2] + E_1(q) \cdot q^{-N}[N - 1] + q^{2-2N} \right)
\]

(8.32)

\( E_2(q) \), which controls reduction of the function \( A_2 \), in the case of \([3, 6]\) is quite tricky: after the term \( q^{21} \), associated with the double box, is subtracted it is not divisible by \((1 - q^2)^2\). Instead the best possible decomposition is

\[
E_2^{[3,6]} = q^9 - 2q^{11} + 2q^{13} - q^{15} + 2q^{17} - 2q^{19} + q^{21} = q^9 (1 - q^2)^2 + \boxed{q^{13}(1 + 2q^4)(1 - q^2)} + \boxed{q^{21}}
\]

(8.33)

or even

\[
E_2^{[3,6]} = q^9 - 2q^{11} + 2q^{13} - q^{15} + 2q^{17} - 2q^{19} + q^{21} = q^9 (1 + q^4)(1 - q^2)^2 + \boxed{q^{15}(1 + q^4)(1 - q^2)} + \boxed{q^{21}}
\]

(8.34)

For the first choice the reduction of \( A_2 \) would be represented as

\[
A_2^{[3,6]} \sim \begin{array}{c|cccccccc}
& q^3 & q^5 & q^7 & q^9 & q^{11} & q^{13} & q^{15} & q^{17} & q^{19} & q^{21} \\
\hline
1 & \checkmark & & & & & & & & & \\
T & & \checkmark & \phantom{\checkmark} & \boxtimes & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} \\
T^2 & \phantom{\checkmark} & & \checkmark & & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} \\
T^3 & \phantom{\checkmark} & & & \checkmark & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} \\
T^4 & \phantom{\checkmark} & & & & \checkmark & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} \\
T^5 & \phantom{\checkmark} & & & & & \checkmark & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} \\
T^6 & \phantom{\checkmark} & & & & & & \checkmark & \phantom{\checkmark} & \phantom{\checkmark} & \phantom{\checkmark} \\
T^7 & \phantom{\checkmark} & & & & & & & \checkmark & \phantom{\checkmark} & \phantom{\checkmark} \\
T^8 & \phantom{\checkmark} & & & & & & & & \checkmark & \phantom{\checkmark} \\
T^9 & \phantom{\checkmark} & & & & & & & & & \checkmark \\
T^{10} & \phantom{\checkmark} & & & & & & & & & \\
T^{11} & \phantom{\checkmark} & & & & & & & & & \\
T^{12} & \phantom{\checkmark} & & & & & & & & & \\
\hline
(0) & (0) & (0) & (1) & (2) & (2) & (2) & (2) & (2) & (1)
\end{array}
\]

(8.35)

The second choice is not minimal, but instead it shifts boxes further to the right – what is always "good" for torus knots and links (and perhaps even more generally, for link diagrams with all vertices black). Whatever
the reason, this choice is the one which provides the right answer and dictates the proper form of reduced table:

\[
A_2^{[3,6]} \sim \\
\begin{array}{cccccccccc}
1 & T & T^2 & T^3 & T^4 & T^5 & T^6 & T^7 & T^8 & T^9 & T^{10} & T^{11} & T^{12} \\
\otimes & 2 & 2 & \otimes & (1 + 2) & \otimes & 2 & \otimes & 2 & \otimes \\
(0) & (0) & (0) & (1) & (−2) & (2) & (−1) & (2) & (−2) & (1)
\end{array}
\]

As a corollary, the contribution of \(A_2(q, T)\) to reduced polynomial is

\[
E_1^{[3,6]} = q^4 + 2q^{14}
\]

but this implies that diagonals in \(A_1\) are rather complicated: they should have no gaps, despite there is a huge gap in \(E_1^{[3,6]}\), and at the same time, modulo 3 boxed term, the contribution should be \textit{positively} divisible by
$1 + q^2 T$. An option, which keeps boxed terms as far to the right as only possible, is

$$A_1^{[3,6]} \sim$$

| $q^2$ | $q^4$ | $q^6$ | $q^8$ | $q^{10}$ | $q^{12}$ | $q^{14}$ |
|-------|-------|-------|-------|--------|--------|--------|
| $1$   | $T^1$ | $T^2$ | $T^3$ | $T^4$  | $T^5$  | $T^6$  |
|       | $T^7$ | $T^8$ | $T^9$ | $T^{10}$ | $T^{11}$ | $T^{12}$ |
|       |       |       |       |       | (0)   | (1)   |
|       |       |       |       |       | (0)   | (0)   |
|       |       |       |       |       | (0)   | (0)   |
|       |       |       |       |       | (0)   | (0)   |
|       |       |       |       |       | (2)   |       |

However, the right option turns to be different:

$$A_1^{[3,6]} \sim$$

| $q^2$ | $q^4$ | $q^6$ | $q^8$ | $q^{10}$ | $q^{12}$ | $q^{14}$ |
|-------|-------|-------|-------|--------|--------|--------|
| $1$   | $T^1$ | $T^2$ | $T^3$ | $T^4$  | $T^5$  | $T^6$  |
|       | $T^7$ | $T^8$ | $T^9$ | $T^{10}$ | $T^{11}$ | $T^{12}$ |
|       |       |       |       |       | (0)   | (1)   |
|       |       |       |       |       | (0)   | (0)   |
|       |       |       |       |       | (0)   | (0)   |
|       |       |       |       |       | (2)   |       |

what contributes

$$\left[(q^{12}T^8 + 2q^{14}T^8) \cdot q^{-N} [N - 1] + q^4 T^2 (1 + q^3 [2T^2 + q^6 T^4]) (1 + q^2 T) \cdot q^{-N} [N - 1]\right] \sim (8.4)$$

$$\sim (1 + 2q^2) q^{12-N} T^8 [N - 1] + q^{4-N} T^2 (1 + q^3 [2T^2 + q^6 T^4]) (q^{2-N} + q^N T) \quad (8.38)$$
Combining the contributions from $A_2$ and $A_1$, we get:

\[
p^{[3,6]}_r = q^{12N-12} \left\{ q^{2-2N} + (1 + 2q^2)q^{12-N}T^8[N-1] + q^{4-N}T^2(1 + q^3[2]T^2 + q^6T^4)(q^{2-N} + q^N T) + \right.
\]
\[+ q^{21}T^{12}[N-1][N-2] + \left(q^{15}T^{10}(1 + 2q^2)(q^{3-N} + q^{N-1}T)[N-1] + \right)
\[q^9T^6(1 + q^4T^2)(q^{2-N} + q^N T)(q^{3-N} + q^{N-1}T) \right\} =
\]
\[= q^{12N-12} \left\{ q^{21}T^{12}[N-1][N-2] + (1 + 2q^2) \left(q^{12-N}T^8 + q^{18-N}T^{10} + q^{N+14}T^{11} \right)[N-1] + \right.
\[+ q^{2-2N} \left( 1 + q^4T^2 + q^{2N+2-T^3} + q^7[2]T^4 + q^{2N+5}[2]T^5 + q^{10}T^6 + q^{2N+8}T^7 + \right)
\[+ q^{12}T^6 + q^{2N+9}[2]T^7 + q^{4N+6}T^8 + q^{16}T^8 + q^{2N+13}[2]T^9 + q^{N+10}T^{10} \right) \right\}
\]

This reproduces (6.94) and thus the answer from [50] and [56] – see discussion after (6.94).

In unreduced case we should just change factors $(q^{2-N}+q^N T)$ wherever they appear to $(q^{1-N}+q^{N+1}T)[N-1]$ and introduce a factor of $[N]$ in all other terms:

\[
p^{[3,6]} = q^{12N-12} \left\{ q^{2-2N}[N] + (1 + 2q^2)q^{12-N}T^8[N][N-1] + \right.
\[+ q^{4-N}T^2(1 + q^3[2]T^2 + q^6T^4)(q^{1-N} + q^{N+1}T)[N-1] + q^{21}T^{12}[N][N-1][N-2] + \right.
\[+ q^{15}T^{10}(1 + 2q^2)(q^{3-N} + q^{N-1}T)[N][N-1] + \right.
\[+ q^9T^6(1 + q^4T^2)(q^{1-N} + q^{N+1}T)(q^{3-N} + q^{N-1}T)[N-1] \right\} =
\]
\[= q^{12N-12} \left\{ q^{21}T^{12}[N][N-1][N-2] + (1 + 2q^2) \left(q^{12-N}T^8 + q^{18-N}T^{10} + q^{N+14}T^{11} \right)[N][N-1] + \right.
\[+ q^{2-2N}[N] + q^{2-2N} \left( q^{3}T^2 + q^{2N+3}T^3 + q^6[2]T^4 + q^{2N+6}[2]T^5 + q^9T^6 + q^{2N+9}T^7 + \right)
\[+ q^{11}T^6 + q^{2N+7} + q^{2N+11}T^7 + q^{4N+7}T^8 + q^{15}T^8 + (q^{2N+11} + q^{2N+15})T^9 + q^{N+11}T^{10} \right) \right\}
\]

This reproduces (6.96). The last two lines can also be rearranged so that conversion of the factor $[N-1]$ into $[N]$ at $T = -1$ gets obvious:

\[
p^{[3,6]} = q^{12N-12} \left\{ q^{21}T^{12}[N][N-1][N-2] + (1 + 2q^2) \left(q^{12-N}T^8 + q^{18-N}T^{10} + q^{N+14}T^{11} \right)[N][N-1] + q^{2-2N}[N] + \right.
\[+ (q^{3}T^2 + q^6[2]T^5 + q^{10}[2]T^5 + q^{2N+7}T^7 + q^{15}T^8 + q^{2N+11}T^9) \right\}
\]
\[+ (1 + q^{2N} T)[N-1] \right\} \right\}
\]

8.4.7 Generic $n$

After these examples, the general structure of the answer for 3-strand torus knots should be partly clear: the matrix $A_2^{[3,n]}$ is reduced to the vicinity of the main diagonal, which ends at $T^{2n}$, while $A_1^{[3,n]}$ – to that of diagonal, which begins at $T^2$. "Vicinity" can consist of additional shorter diagonals under the main ones.

As usual, the structure of reductions is dictated by decomposed Euler characteristic, with additional requirement that diagonals should have no gaps – and to fill the gap one can need to add more diagonals. One more restriction is that contributions of diagonals (minus certain boxed terms for links) should be divisible by $(1 + q^2T)$ - once in the case of $A_1$ and twice in the case of $A_2$.

Anyhow, the starting point are Euler characteristics. Especially simple is

\[
E_1^{[3,n]} = q^4 + (\omega^n + \bar{\omega}^n) \cdot q^{2n+2}
\]

where $\omega = e^{2\pi i/3}$ and $\bar{\omega} = e^{-2\pi i/3}$, i.e. the coefficient in the second term is $-1$ for knots and $+2$ for links. In both cases we have a huge gap in $E_1$, and this means that there will be at least two diagonals – but sometime two will be not enough, as we already saw in the case of $n = 6$. 103
As to $E_2$, it is less trivial. The simplest thing is to draw: for $n = 3k + 1$

| $q^9T^6$ | $q^{11}T^7$ | $q^{13}T^8$ | ... |
|----------|-------------|-------------|-----|
| $n = 4$  | 1           | -2          | 1   |
| $n = 7$  | 1           | -2          | 2   | -1 | 0 | -1 | 2 | -2 | 1 |
| $n = 10$ | 1           | -2          | 2   | -1 | 0 | 0 | 1 | -2 | 1 | 0 | 0 | -1 | 2 | -2 | 1 |
| $n = 13$ | 1           | -2          | 2   | -1 | 0 | 0 | 1 | -2 | 2 | -1 | 0 | -1 | 2 | -2 | 1 |

We added also powers of $T$ which would appear at the main diagonal of reduced $A_2$. Diagonal ends at $q^{4n-3}T^{2n}$. There is clearly a periodicity in $n$ with period 6, not just 3, and we need to consider the six cases separately. In the present paper we briefly describe just one of these cases.

### 8.4.8 Knots from the series $n = 6s + 1$

Here we have pictorially:

$$E_2 = \begin{align*} & (1221)0(1221)0 \ldots 0(1221)0 (1221)0 \ldots 0(1221)0(1221) \\
& I \quad (1222)22(2222)22 \ldots 22(2222)22(2222)22(2222)22(2221) \\
& II \quad (0001)22(1001)22 \ldots 22(1001)22(1001)22(1000) \\
& III \quad (0001)22(2222)22 \ldots 22(2222)22(2222)22(2222)22(1000) \\
& IV \quad (0000)00(1221)00 \ldots 0(1221)0(1221)00 \ldots 00(1221)00(0000) \end{align*}$$

(8.43)

Here (1221) and (1221) denote respectively the sequences $(1, -2, 2, -1)$ and $(-1, 2, -1, 2)$, after that the choice signs in the next lines is obvious. To make these formulas readable we keep brackets in all lines, though they do not carry any other information.

The first line (I) shows, how the gaps are filled in the main diagonal – then to restore the right values of alternated sums we would need to add the next diagonal with the entries (II) – with inverted signs w.r.t. (I). This diagonal is already shorter – has zeroes at the ends, but it solves the problem only for $s = 1(n = 7)$:

$$E_2 \quad (1221)0(1221)$$

$$I \quad (1222)2(2221)$$

$$II \quad (0001)2(1000)$$

For higher $s > 1$ diagonal II still has gaps (zero entries, not located at the ends). Thus we need to change II for III and add a compensating next diagonal IV. This IV has always has gaps, and can not be the final step – instead it is exactly the same as original $E_2$, only shorter, as if $s$ was changed to $s - 1$. One more step would give the right answer for $s = 2$:

$$E_2 \quad (1221)0(1221)0(1221)0(1221)00(1221)$$

$$I \quad (1222)22(2222)22(2222)22(2221)$$

$$III \quad (0001)22(2222)22(2222)22(2222)22(1000)$$

$$V \quad (0000)00(1222)2(2221)00(0000)$$

$$VI \quad (0000)00(0001)2(1000)00(0000)$$

Thus the reduced function $A_2^{[3,6s+1]}$ has the following pattern: it consists of $2s$ diagonals, each shorter by 6 than the previous one, and the last is of length 3:
As to $E_1$, in the case of $n = 6s + 1$ there are just two diagonals, both of length $6s$: one spreads from $q^4T^2$ to $q^{12s+6}T^{6s+1}$, another—just below—from $q^6T^4$ to $q^{12s+4}T^{6s+3}$:

$$A_{[3,6s+1]} \sim$$

| $n = 6s + 1$ | $q^2$ | $q^4$ | $q^6$ | $q^{10}$ | $q^{2n-4}$ | $q^{2n-2}$ | $q^{2n}$ | $q^{2n+2}$ |
|---------------|-------|-------|-------|----------|-----------|-----------|-------|---------|
| 1             |       |       |       |          |           |           |       |         |
| $T$           |       |       |       |          |           |           |       |         |
| $T^2$         |       |       |       |          |           |           |       |         |
| $T^3$         |       |       |       |          |           |           |       |         |
| $T^4$         |       |       |       |          |           |           |       |         |
| $T^5$         |       |       |       |          |           |           |       |         |
| $T^6$         |       |       |       |          |           |           |       |         |
| $T^{n-2}$     |       |       |       |          |           |           |       |         |
| $T^{n-1}$     |       |       |       |          |           |           |       |         |
| $T^n$         |       |       |       |          |           |           |       |         |
| $T^{n+1}$     |       |       |       |          |           |           |       |         |
| $T^{n+2}$     |       |       |       |          |           |           |       |         |
| $T^{2n}$      |       |       |       |          |           |           |       |         |

$$n = 6s + 1$$
From these tables we can easily read expressions for KR polynomials:

\[
P_r^{[3,6s+1]} \sim q^{12s(N-1)} \left\{ 1 + q^4T^2(1 + q^2T^2) \left( 1 + q^4T^2 + \ldots + (q^4T^2)^{3s-1} \right) \frac{q^{2N-2}(1 + q^2T) \cdot q^{-N}[N - 1]}{\sim q^2N-2T} + \left( q^2T^6(1 + q^4T^2 + \ldots + (q^4T^2)^{6s-3}) + q^{15}T^{10} \left( 1 + q^4T^2 + \ldots + (q^4T^2)^{6s-6} \right) + \ldots + q^{12s+3T8s+2} \right) \right\}
\]

and similarly for the unreduced KR polynomial.

It is straightforward, but still instructive to repeat the analysis of sec.~5.7, examine relation to MacDonald dimensions and observe the appearance of \( \gamma \)-factors.

### 8.5 The twisted knot \( 6_1 \)

As any twisted knot this one can be represented in terms of two antiparallel strands and additional lock element (see [73] for details of the twisted knot calculus) – in this representation it was analyzed in [1]. Now we do this in the representation by an ordinary braid –which in this case is 4-strand:

\[
(1, 1, 2, -1, -3, 2, -3): \quad R_1^2R_2R_3^{-1}R_3^{-1}R_2R_3^{-1} \quad \bullet \quad \bullet \quad \circ \quad \circ \quad (8.44)
\]

(we remind that \( R_1 \) and \( R_3 \), as well as projectors \( \pi_1 \) and \( \pi_3 \), commute, thus their mutual ordering is non-essential).

In this case three of the vertices in knot diagram are white, i.e. three inverse \( R \)-matrices are present, and

\[
\left( \frac{q^{4N-4}}{q^{4N}T^3} \right)^{-1} P_r^{6_1} = \operatorname{Tr}_{10 \times 10} \left\{ D \cdot (I + [2]qT\pi_1)^2 \left( I + [2]qT\pi_2 \right) \left( [2]\pi_1 + qT \cdot I \right) \left( [2]\pi_3 + qT \cdot I \right) \left( I + [2]qT\pi_2 \right) \left( [2]\pi_3 + qT \cdot I \right) \right\} = A_{3}^{6_1} q^{-3N} + A_{4}^{6_1} q^{-2N}[N - 1] + A_{5}^{6_1} q^{-N}[N - 1][N - 2] + A_{6}^{6_1} [N - 1][N - 2][N - 3] \quad (8.45)
\]

and all the four functions \( A_k(q, T) \) are cohomologically non-trivial:

| \( A_3^{6_1} \) | \( q^3 \) | \( q^5 \) | \( q^7 \) | \( q^9 \) | \( q^{11} \) | \( q^{13} \) |
|---|---|---|---|---|---|---|
| 1 | 1 | 1 | 4 | 9 | 3 | T |
| \( T^2 \) | 6 | 25 | 18 | 1 | \( T^3 \) | 4 | 30 | 42 | 8 |
| \( T^4 \) | 1 | 16 | 46 | 22 | 1 | \( T^5 \) | 3 | 21 | 28 | 4 |
| \( T^6 \) | 3 | 11 | 8 | 1 | \( T^7 \) | 1 | 2 | 1 |
| (0) | (0) | (1) | (-3) | (3) | (-1) |

\[
\begin{array}{cccccc}
q^3 & q^5 & q^7 & q^9 & q^{11} & q^{13} \\
1 & T & T^2 & T^3 & T^4 & T^5 \\
T^6 & T^7 & & & & \end{array}
\]

\[
= \left( \begin{array}{cccccc}
0 & 0 & 1 & (-3) & 3 & (-1) \\
\end{array} \right)
\]

\[
\sim \left( \begin{array}{cccccc}
0 & 0 & 1 & (-3) & 3 & (-1) \\
\end{array} \right)
\]

Clearly this matrix – and thus its relevant diagonal – satisfies (8.2). Therefore its contribution to reduced KR polynomial is

\[
q^7 T^4[N - 1][N - 2][N - 3](1 + q^2 T)^3 \sim q^7 T^4 \left( q^{2N} + q^N T \right) \left( q^{3-N} + q^{N-1} T \right) \left( q^{4-N} + q^{N-2} T \right) \quad (8.47)
\]
This time the signs of Euler characteristics in columns are not quite alternating – this means that there should be at least two diagonals contributing. Additionally, each diagonal should satisfy (8.2) – this dictates the minimal choice as above. From (8.6) we now get the contribution of $A_2$ to reduced KR polynomial:

$$
\begin{align*}
(q^3T^2(1 + q^2T + q^6T^2) + q^{11}T^5) \cdot q^{-N}[N-1][N-2](1+q^2T)^2 &\sim \\
\sim (q^3T^2 + q^5T^3 + q^{10}[2]T^5) \cdot q^{-N}(q^{2-N} + q^N T)(q^{3-N} + q^{N-1}T) &\quad \text{(8.48)}
\end{align*}
$$

With the help of (8.4) we read the contribution to reduced KR polynomial:

$$
\begin{align*}
q^2T\left(1 + q^2T + q^4T^2 + q^6T^3 + q^{10}T^5\right) \cdot q^{-2N}[N-1](1+q^2T) &\sim \\
\sim q^2T\left(1 + q^2T + q^4T^2 + q^6T^3 + q^{10}T^5\right) \cdot q^{-2N}(q^{2-N} + q^N T) &\quad \text{(8.49)}
\end{align*}
$$

Finally,

$$A_6^6 = q^6T^3$$

(8.50)
Collecting all the four contributions, we obtain:

\[
q^{N-4}T^{-3} \left\{ q^7T^4 \left( q^{2-N} + q^N \right) \left( q^{3-N} + q^{N-1} \right) \left( q^{4-N} + q^{N-2} \right) + \right. \\
+ \left( q^{3T^2} + q^{5T^3} + q^{10[2]T^5} \right) \cdot q^{-N} \left( q^{2-N} + q^N \right) \left( q^{3-N} + q^{N-1} \right) + \\
\left. + q^2T \left( 1 + q^2T + q^4T^2 + q^6T^3 + q^{10T^5} \right) \cdot q^{-2N} \left( q^{2-N} + q^N \right) + q^{6T^3} \cdot q^{-3N} \right\} = \\
= \frac{q^{-2N}}{T^2} + \frac{1}{T} \left( q^{2-2N} + q^{4-2N} \right) + \frac{1}{q^2T} + 2 + (q^2 + q^{2N-2})T + q^2T + q^{2N+2}T^3 + q^{4N}T^4 \\
\quad + T \left( q^6 + q^{12-2N} + q^{2N-2} \right) + T^2 \left( q^{10-2N} + q^{12-2N} + q^4 + q^6 + q^{2N} \right) + \\
\quad + T^3 \left( q^{10-2N} + q^6 + q^{10} + q^{2N+2} + q^{2N+4} + q^{2N+6} \right) + T^4 \left( q^8 + q^{2N+4} + q^{2N+6} + q^{4N} \right) \\
\quad (8.51)
\]

After elimination of underlined and overlined cohomologically trivial pairs, this finally provides

\[
\mathcal{P}_{r}^{61} = \frac{1}{q^{2N}T^2} + \frac{1}{q^2T} + 2 + (q^2 + q^{2N-2})T + q^2T + q^{2N+2}T^3 + q^{4N}T^4 \\
\quad (8.52)
\]

in agreement with \cite{43} and also with \cite{73}, where (sec.5.2.6) the fundamental polynomial for the twisted knot 6\textsubscript{1} was suggested to be \(1 + (1 + A^2 q/t) \{ Aq \} \{ t \} \), what in our current notation, see (6.37), is equal to

\[
\mathcal{P}_{r}^{61} = 1 + (1 + q^{2N}T^2) \left( \frac{1}{q^{2N}T^2} + \frac{1}{q^2T} + q^2T + q^{2N}T^2 \right) \\
\quad (8.53)
\]

what is exactly (8.52).

In unreduced case we should use reduction formulas (8.5),(8.8) and (8.9) to get:

\[
q^{N-4}T^{-3} \cdot q^6T^3 \cdot q^{-3N} [N] + q^{N-4}T^{-3} \left\{ q^7T^4 \left( q^{1-N} + q^{N+1} \right) \left( q^{3-N} + q^{N-1} \right) \left( q^{4-N} + q^{N-2} \right) + \\
\frac{1}{T^2} \cdot q^{-3N} \right\} [N-1] = \\
= q^{1-N} + \left\{ \frac{q^{-2N}}{T^2} + \frac{1}{T} \left( q^{1-2N} + q^{3-2N} \right) + \frac{1}{q} + \left( q^1 + q^{3-2N} \right) + \frac{q^5}{q^2} + q^{5-N} + q^3 + q + \frac{q^{-1}}{q^2} \right\} + \\
\quad + q^2T \left( 1 + q^2T + q^4T^2 + q^6T^3 + q^{10T^5} \right) \cdot q^{-2N} \left( q^{1-N} + q^{N+1} \right) + \\
\quad + T \left( q^6 + q^{12-2N} + q + q^{3} + \frac{q^5}{q^2} + q^{2N-1} \right) + T^2 \left( q^{10-2N} + q^{12-2N} + q^4 + q^6 + q^{2N} \right) + \\
\quad + T^3 \left( q^{10-2N} + q^6 + q^{10} + q^{2N} + q^{2N+2} + q^{2N+4} \right) + T^4 \left( q^8 + q^{2N+4} + q^{2N+6} + q^{4N} \right) \right\} [N-1] = \\
\quad (8.54)
\]

so that

\[
\mathcal{P}_{61} = \left\{ \frac{1}{q^{N+1}T^2} \right\} + \frac{1}{q^2T} + \frac{1}{q} + (q + q^{2N-1})T + q^{2N+1}T^2 + q^{2N+1}T^3 + q^{4N+1}T^4 \right\} [N-1] = \\
= [N] + \left( \frac{1}{q^{N+1}T^2} + \frac{1}{q} + qT + q^{2N+1}T^3 \right)(1 + q^{2N}T)[N-1] \\
\quad (8.54)
\]

Note two pairs of boxed terms – they seem to form cohomologically trivial pairs, but they did not do so in reduced polynomial, therefore we keep them in the unreduced case as well. Note also that if we performed a "deeper" reduction to \([N - 2]\) and \([N - 3]\) in (8.8) and (8.9), the answer (8.54) would also change. However, it is (8.54) that is consistent with the result in \cite{43}, available there for \(N = 2\) and \(N = 3\).
8.6 The 2-component link \(L6a1\), one of the two orientations \((6_3^2(v1)\) of [43])

As usual, the link diagram depends on mutual orientation of knots in the link. In this case both are represented by 4-strand braids. We begin with the simpler one with 8 intersections:

\[ \mathcal{R}_1 \mathcal{R}_2^{-1} \mathcal{R}_3 \mathcal{R}_2^{-1} \mathcal{R}_1 \mathcal{R}_2^{-1} \mathcal{R}_3^{-1} \mathcal{R}_2^{-1} : \]

\[ \bullet \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc \]

This example is distinguished in the present paper, because this was the only case, where we originally disagreed with the previously published results. Now the misprints there are already corrected and there is now a complete agreement. Still, when this paper was being written, the issue was still unclear and we used the chance to demonstrate in detail the trial-and-error process, which leads to what we think is the right answer – even if there is nothing to compare it at the end. Since this may be instructive, we decided to keep this subsection as it was originally written – thus the story will be a little longer than usual.

The four \(A_k\) functions in this case are all cohomologically non-trivial. We begin with their most naive reduction:

\[
\begin{array}{c|cccccc}
\hline
 & q & q^3 & q^5 & q^7 & q^9 & q^{11} & q^{13} \\
\hline
1 & 1 & 3 & 3 & 1 \\
T & 3 & 15 & 22 & 11 & 1 \\
T^2 & 3 & 27 & 62 & 45 & 7 \\
T^3 & 1 & 20 & 84 & 96 & 24 \\
T^4 & 5 & 50 & 115 & 51 & & \\
T^5 & 10 & 60 & 69 & 4 & & \\
T^6 & 10 & 35 & 16 & & & \\
T^7 & 5 & 9 & 2 & & & \\
T^8 & 1 & 1 & & & & \\
\hline
\end{array}
\]

\[
\begin{array}{c|cccccc}
\hline
 & q & q^3 & q^5 & q^7 & q^9 & q^{11} & q^{13} \\
\hline
1 & 1 & 3 & 3 & 1 \\
T & 3 & 15 & 22 & 11 & 1 \\
T^2 & 3 & 27 & 62 & 45 & 7 \\
T^3 & 1 & 20 & 84 & 96 & 24 \\
T^4 & 5 & 50 & 115 & 51 & & \\
T^5 & 10 & 60 & 69 & 4 & & \\
T^6 & 10 & 35 & 16 & & & \\
T^7 & 5 & 9 & 2 & & & \\
T^8 & 1 & 1 & & & & \\
\hline
\end{array}
\]

The contribution to reduced KR polynomial is

\[ q^5 T^3 (1 + q^2 T)^4 [N - 1] [N - 2] [N - 3] \sim q^5 T^3 (1 + q^2 T) \left( q^{2-N} + q^N T \right) \left( q^{3-N} + q^{N-1} T \right) \left( q^{4-N} + q^{N-2} T \right) \]
Note that additional restriction on the choice of diagonals is imposed by divisibility over $(1 + q^2 T)^2$. The contribution to KR polynomial of encycled crosses is

$$qT (1 + 2q^2 T + q^4 T^2 + q^6 T^3 + q^{10} T^4) (1 + q^2 T)^2 \cdot q^{-N} [N - 1][N - 2]$$

$$\sim q^{1-N} T (1 + 2q^2 T + q^4 T^2 + q^6 T^3 + q^{10} T^4) \left( q^{2-N} + q^{N} T \right) \left( q^{3-N} + q^{N-1} T \right)$$
Position of the boxed item in the upper corner is preferable, because then the remaining diagonal is not split into two independent multiples of \((1 + q^2 T)\). The contribution to primary polynomial is

\[
q^4 T^2 \left(1 + q^2 T + q^4 T^2 + q^6 T^3 + q^8 T^4\right) \cdot q^{-2N} (1 + q^2 T)[N - 1] + q^2 T \cdot q^{-2N}[N - 1]
\]

and, finally,

\[
A_0^6\{v1\} = q^8 T^5
\]

Putting all together, we obtain:

\[
\frac{q^{3N-3}}{q^{5N} T^5} \left\{ q^{2-2N} T[N - 1] + q^5 T^3(1 + q^2 T) \right\} \left(q^{2-N} + q^{N-1} T\right) \left(q^{3-N} + q^{N-2} T\right) + 
+ q^{1-N} T \left(1 + 2q^2 T + q^4 T^2 + q^6 T^3 + q^8 T^4\right) \left(q^{2-N} + q^{N-1} T\right) + 
+ q^{4-2N} T^2 \left(1 + q^2 T + q^4 T^2 + q^6 T^3 + q^8 T^4\right) \left(q^{2-N} + q^{N} T\right) + q^{8-3N} T^5 = 
= \frac{[N - 1]}{q^{4N+1} T^4} + \frac{q^{1-5N}}{T^4} + \frac{1}{T^3} \left(q^{3-5N} + q^{5-5N} + q^{1-3N} + q^{-3N-1}\right) + 
+ \frac{1}{T^2} \left(q^{1-5N} + q^{7-5N} + q^{5-5N} + q^{1-3N} + 2q^{1-3N} + 2q^{3-3N} + q^{-3N-3}\right) + 
+ \frac{1}{T} \left(q^{7-5N} + q^{9-5N} + q^{13-5N} + 2q^{5-3N} + q^{7-3N} + q^{9-3N} + 2q^{3-3N} + 2q^{-1-N}\right) + 
+ \left(q^{5-5N} + q^{9-5N} + q^{13-5N} + 2q^{5-3N} + q^{7-3N} + q^{9-3N} + q^{11-3N} + q^{5-N} + q^{3-N} + 2q^{1-N}\right) + 
+ T \left(q^{11-5N} + q^{9-3N} + q^{7-3N} + q^{11-3N} + q^{5-N} + q^{3-N} + q^{3-N} + q^{N-1}\right) + 
+ T^2 \left(q^{9-3N} + q^{7-3N} + q^{N-1}\right)
\]

Eliminating the underlined and overlined pairs with adjacent powers of \(T\), we finally get:

\[
\mathcal{P}_r^6\{v1\} = \frac{[N - 1]}{q^{4N+1} T^4} + \frac{1}{T^3} \left(q^{5-5N} + q^{1-3N}\right) + \frac{1}{T^2} \left(q^{11-5N} + 2q^{1-3N} + q^{-N-3}\right) + \frac{2}{q^{N+1} T} + 
+ \left(q^{3-5N} + 2q^{1-N}\right) + \left(q^{11-5N} + q^{3-N} + q^{N-1}\right) T + q^{N+1} T^2
\]

Of course, at \(T = -1\) this reproduces the right Jones and HOMFLY polynomials

\[
\frac{1}{q^3} - \frac{1}{q^5} + \frac{3}{q^3} - \frac{2}{q^3} + \frac{2}{q} - 2q + q^3
\]
and
\[
\frac{[N-1]}{q^{4N+1}T} + q^{-3N} \left( 2q - \frac{1}{q} \right) + q^{-N} \left( -q^3 + 2q - \frac{2}{q} + \frac{1}{q^2} \right) + q^N \left( q - \frac{1}{q} \right)
\] (8.59)

Still, expression (8.64) looks somewhat suspicious: it seems natural to get rid of the four tilded terms there (which cancel and drop away in reduction to HOMFLY polynomial at \( T = -1 \)). Note, however, that it is not obligatory easy to eliminate these terms by picking up some other diagonals in our tables, because in (8.56) each term with \( q^{-5N} \) is rigidly linked to at least one term with \( q^{-3N} \)—eliminating one, we would unavoidably create another. The only hope is that additionally created terms could form cohomologically trivial combinations. Before demonstrating that this is what actually happens, let us consider the implication of our naive answer for unreduced polynomial—this can help, because unreduced Jones-Khovanov polynomial (at \( N = 2 \)) is available at [79, 80], and there will be at least something to compare with.

In unreduced case (8.56) is changed for
\[
\frac{q^{3N-3}}{q^{5N}T^5} \left\{ q^{2-2N}T[N][N-1] + q^{5T^3(1+q^2T)}(q^{1-N} + q^{N+1T})(q^{3-N} + q^{N-1T})(q^{4-N} + q^{N-2T})[N-1] +
+ q^{1-N}T \left( 1 + 2q^2T + q^4T^2 + q^6T^3 + q^{10T^4} \right) (q^{1-N} + q^{N+1T})(q^{3-N} + q^{N-1T})[N-1] +
+ q^{4-2N}T^2 \left( 1 + q^2T + q^4T^2 + q^6T^3 + q^{8T^4} \right) (q^{1-N} + q^{N+1T})[N-1] + q^{8-3N}[N]T^5 \right\} =
\begin{align*}
&= \frac{[N][N-1]}{q^{4N+1}T^4} + q^{5-5N}[N] + \left\{ \frac{q^{10-5N}}{T^4} + \frac{1}{T^3} \left( \frac{q^{2-5N}}{q^{4-5N} + q^{4-5N} + q^{2-3N}} \right) + \frac{q^{12-5N}}{T^4} + \frac{1}{T^3} \left( \frac{q^{4-5N} + q^{4-5N} + q^{2-3N}}{q^{10-5N} + q^{2-3N}} \right) + \frac{q^{8-3N}}{T^4} + \frac{1}{T^3} \left( \frac{q^{4-5N} + q^{4-5N} + q^{2-3N}}{q^{10-5N} + q^{2-3N}} \right) + \frac{q^{2-3N}}{T^4} + \frac{1}{T^3} \left( \frac{q^{4-5N} + q^{4-5N} + q^{2-3N}}{q^{10-5N} + q^{2-3N}} \right) + \\
&\quad + \frac{1}{T^2} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) + \frac{1}{T} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) + \frac{1}{T^2} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) + \frac{1}{T} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) +
&\quad + T \left( q^{10-5N} + q^{8-5N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) +
&\quad + \frac{1}{T^2} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) + \frac{1}{T} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) \right\}[N-1]
\] (8.60)

The reason why the boxed term is paired with the one in lower rather than in the upper adjacent line is that it did so in reduced case. Thus
\[
P^6_{G(1)} = \frac{[N][N-1]}{q^{4N+1}T^4} + q^{5-5N}[N] + \left\{ \frac{q^{10-5N}}{T^4} + \frac{1}{T^3} \left( \frac{q^{2-5N}}{q^{4-5N} + q^{4-5N} + q^{2-3N}} \right) + \frac{q^{12-5N}}{T^4} + \frac{1}{T^3} \left( \frac{q^{4-5N} + q^{4-5N} + q^{2-3N}}{q^{10-5N} + q^{2-3N}} \right) + \frac{q^{8-3N}}{T^4} + \frac{1}{T^3} \left( \frac{q^{4-5N} + q^{4-5N} + q^{2-3N}}{q^{10-5N} + q^{2-3N}} \right) + \frac{q^{2-3N}}{T^4} + \frac{1}{T^3} \left( \frac{q^{4-5N} + q^{4-5N} + q^{2-3N}}{q^{10-5N} + q^{2-3N}} \right) + \frac{1}{T^2} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) + \frac{1}{T} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) + \frac{1}{T^2} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) + \frac{1}{T} \left( \frac{q^{10-5N} + q^{8-5N}}{q^{10-5N} + q^{2-3N}} + q^{8-3N} + q^{12-3N} + q^{6-N} + q^{4-N} + q^2-N + q^N \right) \right\}[N-1]
\] (8.61)

Now we can compare this expression at \( N = 2 \) with the unreduced Jones-Khovanov polynomial from [79, 80], which for this purpose should be appropriately regrouped:
\[
\frac{[2]}{q^9T^4} + \frac{1}{q^{9T^3}} + \frac{2q^6 + q^4}{q^4T^2} + \frac{2q^{-2} + 1}{q^2} + \frac{1}{q^2} \left( 1 + q^2 \right)
\] (8.62)

From this formula their can be no doubt that one should somehow eliminate the tilded terms in (8.61), simultaneously modifying the double-tilded one, and that the right answer is:
\[
P^6_{G(1)} = \frac{[N][N-1]}{q^{4N+1}T^4} + q^{1-N}[N] + \left( \frac{1}{q^{3N+2}T^3} + \frac{2}{q^{3N}T^2} + q^{-N} + q^2-N T \right) \left( 1 + q^{2N} T \right)[N-1]
\] (8.63)

In reduced case this would imply
\[
P^6_{e(1)} = \frac{[N-1]}{q^{4N+1}T^4} + q^{1-N} + \left( \frac{1}{q^{3N+2}T^3} + \frac{2}{q^{3N}T^2} + q^{-N} + q^2-N T \right) \left( 1 + q^{2N} T \right)
\] (8.64)
Note that this is exactly (8.57) with the tilded terms omitted (as we suspected from the very beginning) – but now we have a better representation in the first line, which provides a tool for modifying original tables.

As an intermediate step we can make another table: representing the coefficient in front of \((1 + q^{4N-2})\)

\[
\begin{array}{c|c|c|c|c}
T & A_3 & A_2 & A_2^{aux} & A_3 & A_3^{aux} \\
T & & & & & \\
T^3 & & & & & \\
q^{12-2N} & & & & & \\
T^4 & q^{8} + q^{5} & q^{14-2N} & 2q^{6-2N} & q^{12-2N} & \times \\
q^{2N+2} & \times & \times & \times & \times & \times \\
q^{2N+4} & \times & \times & \times & \times & \times \\
\end{array}
\]

In the columns from \(A_3\) and \(A_2\) the verticals are rigid: they are defined by the factors \((q^{3-N} + q^{-N}T)\) and \((q^{4-N} + q^{N-1}T)\) In the case of \(A_1\) all items should be in separate columns, we put them in one just to save space. Thus the freedom is to add columns. The boxed elements are the ones from the answer – from the first line in (8.64), they and thus the corresponding columns, should be contributing. At the same time the non-boxed elements from these *must* columns should drop away from the answer (8.64), i.e. should enter some cohomologically trivial pairs. Such pairs are formed by identical entries at some two adjacent lines. Clearly, the content of the tree sets of columns \(A_3, A_2, A_1\) is not sufficient to provide all the needed cancellations. But adding additional columns in \(A_2^{aux}\) and \(A_3^{aux}\) solves the problem and reproduces (8.64). However, addition of extra columns means that their counterparts should be added into our original reduced (diagonal) tables:

\[
\begin{array}{c|c|c|c|c|c|c|c|c}
q^{-1} & q & q^3 & q^5 & q^7 & q^9 & q^{11} & q^{13} & q^{15} \\
1 & & & & & & & & \\
T & \times & \times & \times & \times & \times & \times & \times & \times \\
T^2 & & & & & & & & \\
T^3 & 4\times & 4\times & 4\times & 4\times & 4\times & 4\times & 4\times & 4\times \\
T^4 & 6\times & 6\times & 6\times & 6\times & 6\times & 6\times & 6\times & 6\times \\
T^5 & 5\times & 5\times & 5\times & 5\times & 5\times & 5\times & 5\times & 5\times \\
T^6 & 3\times & 3\times & 3\times & 3\times & 3\times & 3\times & 3\times & 3\times \\
T^7 & 2\times & 2\times & 2\times & 2\times & 2\times & 2\times & 2\times & 2\times \\
T^8 & \times & \times & \times & \times & \times & \times & \times & \times \\
\end{array}
\]

\[
\begin{array}{c|c|c|c|c|c|c|c|c}
q^{-1} & q & q^3 & q^5 & q^7 & q^9 & q^{11} & q^{13} & q^{15} \\
1 & & & & & & & & \\
T & \times & \times & \times & \times & \times & \times & \times & \times \\
T^2 & & & & & & & & \\
T^3 & 4\times & 4\times & 4\times & 4\times & 4\times & 4\times & 4\times & 4\times \\
T^4 & 6\times & 6\times & 6\times & 6\times & 6\times & 6\times & 6\times & 6\times \\
T^5 & 5\times & 5\times & 5\times & 5\times & 5\times & 5\times & 5\times & 5\times \\
T^6 & 3\times & 3\times & 3\times & 3\times & 3\times & 3\times & 3\times & 3\times \\
T^7 & 2\times & 2\times & 2\times & 2\times & 2\times & 2\times & 2\times & 2\times \\
T^8 & \times & \times & \times & \times & \times & \times & \times & \times \\
\end{array}
\]

\[
A_2 \sim (0) \quad (1) \quad (4) \quad (6) \quad (5) \quad (3) \quad (0) \quad (2) \quad (1) \\
A_3 \sim (0) \quad (1) \quad (4) \quad (6) \quad (5) \quad (3) \quad (0) \quad (2) \quad (1)
\]
At the level of these diagonals one could also consider shifting a couple of elements in the $A_1$ table to positions of crosses – but this is forbidden, because in the full table $A_1$ there was nothing at these positions – and reduction assumes that one can not produce negative contributions neither in the remnant nor in the ratio.

With this choice we get instead of (8.56):

$$
\frac{q^{3N-3}}{q^{3N+5}T} \left\{ q^{2-2N}T[N-1] + q^5 T^3 (1 + q^2 T) \left( q^{3-N} + q^{N-1} T \right) \left( q^{4-N} + q^{N-2} T \right) + q^{1-N} T \left( 1 + 2q^2 T + q^4 T^2 + q^7 [2] T^3 + q^9 [2] T^4 \right) \left( q^{2-N} + q^{N-1} T \right) + q^{1-2N} T^2 \left( 1 + 2q^2 T + q^3 [2] T^2 + q^6 T^3 + q^8 T^4 \right) \left( q^{2-N} + q^{N} T \right) + q^{8-3N} T^5 \right\} = \\
\frac{[N-1]}{q^{4N+1} T^4} + \frac{q^{1-5N}}{T^4} + \frac{1}{T^3} \left( q^{3-5N} + 2q^{5-5N} + q^{1-3N} + q^{3N-1} \right) + \\
\frac{1}{T^2} \left( 2q^{5-5N} + q^{1-3N} + q^{11-5N} + q^{7-5N} + q^{3N-3N} + 3q^{3N-3N} + 2q^{1-3N} + q^{N-3} \right) + \\
+ T \left( q^{11-5N} + q^{11-3N} + q^{9-N} + 2q^{7-3N} + q^{5-N} + q^{3-N} + q^{3N} + q^{1-N} \right) + \\
+ T^2 \left( q^{3N+1} + q^{5-N} + q^{5N} + q^{N+1} \right) \tag{8.65}
$$

and elimination of underlined and overlined terms leads to (8.64):

$$
\mathcal{P}_{r}^{5(v+1)} = \frac{[N-1]}{q^{4N+1} T^4} + \frac{1}{q^{4N+1} T^3} + \left( 2 q^{3N-1} + \frac{1}{q^{N+3}} \right) \frac{1}{T^2} + \frac{2}{q^{N+1} T} + 2q^{1-N} + \left( q^{3-N} + q^{N-1} T + q^{N+1} T^2 \right) \tag{8.66}
$$
Unreduced version is:

\[
\frac{q^{3N-3}}{q^{5N^2}} \left\{ q^{2-2N}[N][N-1] + q^5T^3(1 + q^2T) \left( q^{1-N} + q^{N+1}T \right) \left( q^{1-N} + q^{N-1}T \right) \left( q^{1-N} + q^{-N-2}T \right) [N-1] + \\
+ q^{1-N}T \left( 1 + 2q^2T + q^4T^2 + q^7[2]T^3 + q^8[2]T^4 \right) \left( q^{1-N} + q^{N+1}T \right) \left( q^{1-N} + q^{N-1}T \right) [N-1] + \\
+ q^{4-2N}T^2 \left( 1 + 2q^2T + q^3[2]T^2 + q^6T^3 + q^8T^4 \right) \left( q^{1-N} + q^{N+1}T \right) [N-1] + q^{8-3N}T^5[2] \right\} = \\
= \left[ \frac{[N][N-1]}{q^{4N+1}} \right] + \frac{q^{2-5N}}{T^4} + \frac{1}{T^3} \left( q^{2-5N} + 2q^{4-5N} + q^{-3N-2} \right) + \frac{1}{T^2} \left( 2q^{4-5N} + q^{10-5N} + q^{6-5N} + 2q^{-3N} \right) + \\
+ \frac{1}{T} \left( q^{10-5N} + q^{6-5N} + q^{2-5N} + q^{5-5N} + q^{6-3N} + q^{4-3N} + q^{4-5N} + q^{2-3N} \right) + \\
+ \left( q^{12-5N} + q^{6-5N} + q^{6-3N} + q^{4-3N} + q^{10-5N} + q^{8-3N} + q^{6-3N} + q^{-N} \right) + \\
+ T \left( q^{10-5N} + q^{8-3N} + q^{6-3N} + q^{2-3N} \right) \left( 1 + q^{2N}T \right) [N-1] + \left[ \frac{q^{5-5N}[N]}{T} \right] \right) (8.67)
\]

To convert the terms in boxes we need an additional manipulation:

\[
(q^{2-3N} + q^{4-5N})^\frac{1}{T}(1 + q^{2N}T)[N-1] + q^{5-5N}\left[ \frac{[N][N-1]}{q^{4N+1}} \right] = \\
= \frac{q^{2-3N}}{T} \left( 1 + q^{2N}T \right) [N-1] + \left( \frac{q^{4-5N}}{T} + q^{4-3N} + q^{2-5N} \right) [N-1] + q^{4-4N} \sim \\
\sim \frac{q^{2-3N}}{T} \left( 1 + q^{2N}T \right) [N-1] + q^{3-3N}\left[ \frac{[N]}{T^4} \right] + \left( \frac{q^{2-3N}}{T} + q^{2-N} + q^{4-3N} \right) [N-1] + q^{2-2N} \sim q^{1-N}\left[ \frac{[N]}{T^4} \right] \right) (8.68)
\]

and finally we arrive at (8.63):

\[
\rho_{6^2(1)} = \frac{[N][N-1]}{q^{4N+1}T^4} + q^{-N}\left[ \frac{[N]}{T^4} \right] + \left( \frac{1}{q^{3N+2}T^3} + \frac{2}{q^{3N^2T^2} + q^{-N} + q^{2-N}T} \right) (1 + q^{2N}T)[N-1] (8.69)
\]

Thus we obtain what seems to be the right answers for reduced and unreduced KR polynomials for \( 6^2_3(v2) \). These answers are consistent with the known unreduced Jones-Khovanov polynomial, but inconsistent with the answers from[43] (which, however, are in any case incorrect for this particular link). Not only we got the presumably correct formulas, we also reconstructed the relevant differentials, whose cohomologies provide these answers – in the future it remains only to compose these differentials from the morphisms, suggested in [1].

In fact, eqs.(8.66) and (8.69) appear to coincide with the corresponding answers in [43].

8.7 The 2-component link \( L6a1, \) another orientation (\( 6^2_3(v2) \) of \([43]\))

In this orientation the braid is still 4-strand, but has 10 intersections:

\[
R_1R_2R_3R_2R_1^{-1}R_2^2R_3^{-1}R_2:
\]

\[
\circ \quad \bullet \quad \bullet \quad \bullet \quad \bullet \quad \bullet \quad \bullet \quad \bullet \quad \bullet \quad \bullet
\]
The function $A_2^{62, 2}$ is cohomologically trivial,

\[
A_2^{62, 2} = \begin{bmatrix}
1 & 1 & 2 & 1 \\
2 & 22 & 16 & 4 \\
1 & 76 & 126 & 53 & 4 \\
139 & 435 & 350 & 91 \\
159 & 782 & 1083 & 551 & 91 \\
119 & 826 & 1764 & 1484 & 525 & 63 \\
57 & 539 & 1642 & 2086 & 1217 & 320 & 29 \\
2 & 46 & 278 & 683 & 1217 & 534 & 174 & 25 & 1 \\
4 & 42 & 144 & 238 & 212 & 102 & 24 & 2 \\
2 & 11 & 25 & 30 & 20 & 7 & 1 \\
0 & 0 & 0 & (−1) & (3) & (−3) & (1) & (0) & (0) & (0)
\end{bmatrix}
\]

Contribution of the middle diagonal to reduced polynomial is

\[
q^8 T^5 (1 + q^2 T)^3 \cdot q^{-N} [N - 1] [N - 2] \quad (8.6) \quad q^{8-N} T^5 (1 + q^2 T) \left( q^{2-N} + q^N T \right) \left( q^{3-N} + q^{N-1} T \right) \quad (8.71)
\]
Contribution of the middle diagonal to reduced polynomial is

\begin{align*}
A_1^{62(v2)} = q_3 \times q_5 \times q_7 \times q_9 \times q_{11} \times q_{13} \times q_{15} \times q_{17} \times q_{19}
\end{align*}

|       | $q_3$ | $q_5$ | $q_7$ | $q_9$ | $q_{11}$ | $q_{13}$ | $q_{15}$ | $q_{17}$ | $q_{19}$ |
|-------|-------|-------|-------|-------|----------|----------|----------|----------|----------|
| 1     | 1     | 1     |       |       |          |          |          |          |          |
| $T$   | 4     | 14    | 4     |       |          |          |          |          |          |
| $T^2$ | 3     | 53    | 53    | 4     |          |          |          |          |          |
| $T^3$ |       | 91    | 211   | 91    |          |          |          |          |          |
| $T^4$ |       | 91    | 392   | 392   | 91       |          |          |          |          |
| $T^5$ |       | 63    | 406   | 721   | 406      | 63       |          |          |          |
| $T^6$ |       | 29    | 263   | 707   | 707      | 263      | 29       |          |          |
| $T^7$ |       | 8     | 105   | 403   | 612      | 403      | 105      | 8        |          |
| $T^8$ |       | 1     | 23    | 129   | 279      | 279      | 129      | 23       | 1        |
| $T^9$ |       | 2     | 20    | 62    | 88       | 62       | 20       | 2        |          |
| $T^{10}$ |     | 1     | 5     | 10    | 10       | 5        | 1        |          |          |

Putting all the three contributions together and restoring the common factor $q^{8(N-1)}/(q^NT)^2$, we obtain

\begin{align*}
q^{4N}T^3 + q^6N\ T^3 - 2\left\{ q^{8-N}T^3(1 + q^2T + q^6T^3 + q^8T^4)\left( q^{3-N} + q^N \right) \right. +
q^{5-2N}T^3(1 + 2q^2T + q^6T^3 + q^8T^4)\left( q^{2-N} + q^N \right) + q^{11-2N}T^6[N - 1]
\end{align*}

\begin{align*}
A_{62}^{62(v2)} = q^5T^2
\end{align*}

Putting all the three contributions together and restoring the common factor $q^{8(N-1)}/(q^NT)^2$, we obtain

\begin{align*}
q^{4N+3}[N - 1]T^4 + q^6N-8T^{-2}\left\{ q^{8-N}T^5(1 + q^2T)\left( q^{2-N} + q^N \right) \right. \\
+ q^{3-N}T^5(1 + 2q^2T + q^6T^3 + q^8T^4)\left( q^{3-N} + q^N \right) + q^{3-3N}T^2 \right\} =
\end{align*}

\begin{align*}
= q^{4N+3}[N - 1]T^4 + q^3N-3\left\{ 1 + q^2T + (q^2N + q^4N^2T^2) + (2q^{2N+2} + q^8T^3) +
+ (q^{2N+4} + q^{2N+6} + q^{10} + q^{12})T^4 + (q^{4N+2} + q^{2N+6} + q^{10} + q^{2N+6} + q^{2N+8})T^5 + (q^{4N+4} + q^{2N+8})T^6 \right\}
\end{align*}
Thus
\[ P_{r}^{62(v2)} = q^{3N-3}\left\{ 1 + q^{2}T + (q^{2N} + 2q^{4})T^{2} + 2q^{2N+2}T^{3} + q^{4+2N}T^{4} + (q^{4N+2} + q^{2N+6})T^{5} + q^{4N+4}T^{6}\right\} + \]
\[ + q^{4N+3}[N - 1]T^{4} \]
- in agreement with [43].

In unreduced case (8.74) changes for
\[ q^{4N+3}[N][N - 1]T^{4} + q^{6N-8}T^{-2}\left\{ q^{8-N}T^{5}(1 + q^{2})\left(q^{1-N} + q^{N+1}T\right)\left[q^{3-N} + q^{N-1}T\right][N - 1] + \]
\[ + q^{5-2N}T^{3}(1 + 2q^{2}T + q^{6}T^{3} + q^{8}T^{4})\left(q^{1-N} + q^{N+1}T\right)[N - 1] + q^{5-3N}T^{2}[N]\right\} = \]
\[ = q^{4N-4} + q^{4N+3}[N][N - 1]T^{4} + q^{3N-4}\left\{ 1 + q^{2}T + (q^{2N+2} + 2q^{4})T^{2} + (2q^{2N+4} + q^{8})T^{3} + \right\}
\[ + (q^{2N+4} + q^{2N+8} + q^{10} + q^{8})T^{4} + (q^{4N+4} + q^{2N+8} + q^{10} + q^{2N+6} + q^{2N+10})T^{5} + (q^{4N+6} + q^{2N+10})T^{6}\right\}[N - 1] \]

\[ P_{r}^{62(v2)} = q^{3N-3}[N] + q^{3N-4}\left\{ q^{2}T + (q^{2N+2} + 2q^{4})T^{2} + 2q^{2N+4}T^{3} + q^{4N+4}T^{4} + (q^{4N+4} + q^{2N+6})T^{5} + q^{4N+6}T^{6}\right\}[N - 1] + \]
\[ + q^{4N+3}[N][N - 1]T^{4} \]

This is again in accordance with the answers for \( N = 2, 3 \) in [43]. As usual, there are some pairs in unreduced polynomial that can seem to be cohomologically trivial – but since they were not such in reduced case, they survive in unreduced polynomial as well.

**8.8 A thick knot 9_{42}**

This knot is especially interesting for superpolynomial calculus, because it is surrounded by certain controversies since the very first analysis in [50]. It is represented by the 4-strand braid

\[ (1, 1, 1, -2, -1, -1, 3, -2, 3) : \quad R_{3}^{3}R_{2}^{-1}R_{1}^{-2}R_{3}R_{2}^{-1}R_{3} \]
The function $A_3^{42} \sim (1 + T)$ is cohomologically trivial, thus we can start from $A_2$.

\[
A_2^{42} = \begin{array}{cccccccccc}
1 & q^2 & q^4 & q^6 & q^8 & q^{10} & q^{12} & q^{14} & q^{16} & q^{18} \\
1 & 1 & 4 & 6 & 4 & 1 \\
T & 3 & 20 & 43 & 38 & 12 \\
T^2 & 3 & 34 & 134 & 181 & 92 & 14 \\
T^3 & 1 & 24 & 185 & 444 & 361 & 116 & 11 \\
T^4 & 6 & 125 & 544 & 745 & 398 & 85 & 5 \\
T^5 & 44 & 356 & 805 & 698 & 261 & 37 & 1 \\
T^6 & 9 & 131 & 466 & 634 & 383 & 102 & 9 \\
T^7 & 1 & 26 & 144 & 293 & 273 & 120 & 22 & 1 \\
T^8 & 2 & 21 & 64 & 88 & 60 & 19 & 2 \\
T^9 & 1 & 5 & 10 & 10 & 5 & 1 \\
\end{array}
\]

This time there are three possible choices of diagonal – as usual, we take the middle one. The resulting contribution to reduced KR polynomial is

\[
q^4T^2(1 + q^4T^2)(1 + q^2T^2) \cdot q^{-N}[N - 1][N - 2] \sim q^{4-N}T^2(1 + q^4T^2)\left(q^{2-N} + q^N T\right)\left(q^{3-N} + q^{N-1}T\right) (8.77)
\]

The next function
The four crosses in boxes are non-minimal – alternated sums allow to skip them. Still, one of them completes the main diagonal and can look desirable. In the next formulas we put their contributions in boxes to show what their role is. The main diagonal contributes
\[
q \left( 1 + q^4(T^2 + T^3) \right) + T^3q^6 + T^5q^{10} \cdot q^{-2N}(1 + q^2T)[N - 1]
\]
\[
q^{1-2N} \left( 1 + q^4(T^2 + T^3) \right) + T^3q^6 + T^5q^{10} \left( q^{2-N} + q^NT \right)
\]
Finally,
\[
A^q_{942} = q^7T^4
\]
Collecting all the three contributions we obtain:
\[
q^{N-5T-4} \left\{ q^{4-N}T^2(1 + q^4T^2)(q^{2-N} + q^NT) \left( q^{3-N} + q^{N-1}T \right) + q^{1-2N} \left( 1 + \frac{q^4}{T} + \frac{T^3}{T} \right) + T^3q^6 + T^5q^{10} \left( q^{2-N} + q^NT \right) + q^{7-3N}T^4 \right\} =
\]
\[
= \frac{1}{q^{2N+2T^4}} + \frac{1}{q^{4T^3}} + \frac{q^{4-2N}}{T^2} \left( q^{4-2N} + 1 + \frac{q^2}{T} \right) + \left( \frac{q^{2-2N}}{T} + \frac{q^{2-2N}}{T} \right) + \left( \frac{q^{8-2N}}{T} + q^4 + \frac{q^6}{T} + \frac{q^{2N+2}}{T} \right)
\]
If we neglected the terms in boxes, then elimination of all the underlined and overlined cohomologically trivial pairs would give:
\[
\frac{1}{q^{2N+2T^4}} + \frac{1}{q^{4T^3}} + \frac{1}{T} + (q^{2-2N} + q^{2N-2}) + q^4T + q^{2N+2}T^2
\]
This is, however, inconsistent with [50, 59]: in particular, does not reproduce properly the Jones-Khovanov polynomial at \( N = 2 \). To get the right answer we should take into account the boxed terms. Then the tilded pair can also be eliminated and we obtain a non-minimal answer
\[
A^q_{942} = \frac{1}{q^{2N+2T^4}} + \frac{1}{q^{4T^3}} + \frac{q^{2-2N}}{T^2} + \frac{2}{T} + (1 + q^{2N-2}) + q^4T + q^{2N+2}T^2
\]
\( a = q^N \), no additional reductions are needed. On one hand, we can not decide if addition of these items is indeed necessary – before we explicitly construct and investigate the morphisms (which should be the same for all link diagrams at once). On another hand, if the boxed items are not added, then the well established Jones-Khovanov polynomialat \( N = 2 \) is not reproduced – and it definitely should be a particular choice of KR polynomial in our construction. Thus we believe that they should be added – and then KR polynomial and superpolynomial are just the same – at least for \( 9_{42} \) and other examples in this paper. Still, at this level (without explicit morphisms) we refrain from a final judgement.

Anyhow, we can now immediately obtain the unreduced counterpart of (8.81) – with additional terms in boxes. Instead of (8.79) we now have:

\[
q^{N-5}T^{-4} \left\{ q^{4-N}T^2(1+q^4T^2) \left( q^{1-N} + q^{N+1}T \right) \left( q^{3-N} + q^{N-1}T \right) [N-1] + \\
+q^{1-2N} \left( 1 + \frac{q^4(T^2+T^3)}{T^2} + T^3q^6 + T^5q^{10} \right) \left( q^{1-N} + q^{N+1}T \right) [N-1] + q^{7-3N}T^4 \left[ N \right] \right\} = \\
= q^{1-N} \left\{ \frac{1}{q^{2N+3}T^4} + \frac{1}{q^2T^3} + \frac{q^{3-2N}}{T^2} + (q^{3-2N} + q^{-1} + q^3) \frac{1}{T} + (q^{1-N} + q^{N-1} + q^3 + q^{2N-1}) + \\
+q^{1-2N} \frac{T^2}{q^2T^3} + \frac{q^{1-N}T}{T} + \frac{q}{T} + q \right\} [N-1] =
\]

and

\[
\mathcal{P}^{942} = q^{1-N} + \left\{ \frac{1}{q^{2N+3}T^4} + \frac{1}{q^2T^3} + \frac{q^{1-2N}}{T^2} + \frac{2}{T} + (q + q^{2N-1}) + q^3T + q^{2N+3}T^2 \right\} [N-1] = \\
= \left[ N \right] + \left\{ \frac{q^{1-N} + q^{[N-1]}}{q^{2N+3}T^4} + \frac{q^{1-2N}}{T^2} + \frac{1}{qT} + q^3T \right\} (1 + q^{2N}T)[N-1] \quad (8.82)
\]

Somewhat remarkably, in this expression there are no longer pairs, which look cohomologically trivial: the item \( q \), which could be combined with \( q/T \), is naturally absorbed into \([N]\).

9 Beyond braids

Concise technique from the previous section has a lot of advantages. It overcomes explicit construction of spaces \( v \) and works directly with the primary polynomial \( \mathfrak{P}^L \). We remind that coefficients in front of powers of \( T \) in \( \mathfrak{P} \) are spaces in the KR complex, which are complicated sums over vertices of the hypercube, i.e. complicated (big) direct sums of the spaces \( v \). The potential drawback of this approach is that it requires a construction of differentials, which does not directly refer to elementary morphisms between the spaces \( v \), which act along the hypercube edges. We demonstrated above that differentials possess some recognizable properties, but it is unclear, whether these mnemonic rules can be finally promoted to a self-sufficient theory, not referring to morphisms at all.

Anyhow, whatever can be done directly with \( \mathfrak{P} \) has advantages, because this primary polynomial is as simply calculable, as HOMFLY. So far – including the previous section – we mostly relied upon braid representation, what is justified, because from [58, 68] we know an absolutely explicit and practically working construction for arbitrary braid (moreover, in [69] it is extended to colored polynomials – though we do not need them at present, they can be important for the study of colored KR polynomials, if they exist). Still, it often happens that simple knots/links are represented by rather complicated braids – and then it can make sense to use alternative constructions of \( \mathfrak{P} \). In what follows we discuss just two examples. The first will be the series of twist knots and antiparallel 2-strand braids – a very simple one, but with a braid representation, where the number of strands grows along the series, and this gets increasingly complicated. The second will be the skein relations – since we are dealing with the fundamental representation, they can be easily modified for evaluation of \( \mathfrak{P} \) instead of HOMFLY – and thus applied to the same extent as the usual skein relations are.
9.1 Twist knots

For detailed description of knot polynomials for twist knots see sec.5.2 of [73] and especially sec.5.7 of [1]. We borrow an introductory piece from [1] for a brief description.

Twist knots form one of the simplest 1-parametric families (see, for example, sec.5.2 of [73]), which includes unknot, trefoil and the figure-eight knot $4_1$. They are made out of the 2-strand braid, only – in variance with the torus knots – anti-parallel:

Here $k$ can be both positive and negative. If the number of crossing in the antiparallel braid is odd, this changes orientation at the two-vertex ”locking block”. The corresponding knot diagrams (after rotation by $90^\circ$) are:

The two pictures correspond respectively to the cases when the number $p$ of circles – and thus the number $p+2$ of vertices – is even and odd. The two cases are essentially different, already when all the vertices are black, i.e. at the main Seifert vertex of the hypercube, configurations are not the same:

Still, the number of cycles in both cases is $p + 1$, so that in both cases the hypercube vertex $b^{p+2}$ contributes $N^{p+1} \rightarrow [N]^{p+1}$. When some vertex is changed from black to white, one subtracts a contribution with a crossing at this vertex, what changes the number of cycles: for example, when there is just one white vertex, subtraction contains $p$ cycles, and the contribution of $b^{p+1}w$ vertex in the hypercube is $N^{p+1} - N^p \rightarrow [N]^p[N - 1]$.

When all vertices are of the same color then the knot is $(p + 1)_2$ for even $p$ and $(p + 2)_2$ for odd $p$. If the two vertices at the top (two ”horizontal” vertices) have the opposite color to the $p$ vertical ones, then the knot is $(p + 2)_1$ for even $p$ and $(p + 1)_1$ for odd $p$. When the two horizontal vertices are of different colors, we get an unknot. If some vertical vertices have different colors, what matters is their algebraic sum, $p \equiv z_b - z_w$. The
answer for HOMFLY polynomials of the twisted knots is well known, see, for example, sec.5.2 of [73]:

\[ H_k = 1 + F_k(A^2)\{Aq\} \{A/q\} = 1 + F_k \left( q^{2N} - q^2 - q^{-2} + q^{-2N} \right) \]  

(9.1)

with \( F_k(A^2) = -A^{k+1}\{A^k\}/\{A\} \). For \( k = 0 \) and \( F_0 = 0 \) we get unknot, for \( k = 1 \) and \( F_1 = -A^2 \) – the trefoil \( 3_1 \) and for \( k = -1 \) and \( F_{-1} = 1 \) – the figure eight knot \( 4_1 \). More generally, for positive \( k \) we get the knots \( (2k+1) \), while for negative \( k = -(2-2k) \) in the Rolfsen notation, see [79]. Note that trefoil \( 3_1 \) gets its right place in the series of twisted knots, if treated as \( 3_2 \).

| \( p \) | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | ... |
| --- | --- | --- | --- | --- | --- | --- | --- | --- | --- | --- |
| \( k \) | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 11 |
| \( m \) | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 10 |

We added to this table the lines with the values of \( k \), which appears in (9.1) and of the minimal number \( m \) of strands in the braid representation. We see that \( m \) grows linearly with \( p \) – this is what makes consideration of the family of twist knots orthogonal to that of the families with given \( m \), which we concentrated on in the present paper.

However, for twist knots we know the spaces \( v \) (they were found in paper\(^5\) [1] – and this is enough to apply the technique that we developed here. We denote by \( i \) the number of white vertices on the vertical, thus \( 0 \leq i \leq p \). There are \( C_p^i \) vertices of each type, and

\[
\begin{align*}
    v_i^{**} &= [N]^{p+1-i}[N-1]^i \\
    v_i^{*o} &= v_i^{o*} = [N]^{p-i}[N-1]^{i+1} \\
    v_i^{oo} &= [2][N]^{p-i}[N-1]^{i+1}
\end{align*}
\]  

(9.2)

for \( 0 \leq i \leq p-1 \) while for \( i = p \) dimensions are more complicated. Moreover, they are different, depending on the parity of \( p \): for odd \( p \)

\[
\begin{align*}
    v_p^{**} &= [N][N-1]^p \\
    v_p^{*o} &= v_p^{o*} = [N][N-1] \cdot Y_p \\
    v_p^{oo} &= [2][N][N-1] \cdot Y_p
\end{align*}
\]  

(9.3)

and for even \( p \)

\[
\begin{align*}
    v_p^{**} &= [N]^2[N-1] \cdot Y_{p-1} \\
    v_p^{*o} &= v_p^{o*} = [N][N-1]^2 \cdot Y_{p-1} \\
    v_p^{oo} &= [N][N-1]^p + [N][N-1][N-2] \cdot Y_{p-1}
\end{align*}
\]  

(9.4)

\(^5\)The second version of that paper is needed, the first version (and the journal one) were inadequate in the twisted-knot section 5.7.
where
\[ Y_{k+2} = [N - 1]^k[N - 2] + Y_k = [2] + \sum_{i=0}^{k+2} [N - 1]^{2i+1}[N - 2] \] (9.5)

These formulas provide primary polynomials and it is a straightforward exercise to extract from them the KR polynomials. In the following section we use this knowledge for a closely related family, which includes $6_2^1(v2)$ – the last 2-component link from the list of [43], that we have not yet described. In fact, a minor generalization is needed for $6_1^1(v1)$ – and we complete filling the list of [43] by making this example in s.9.3.

9.2 2-component links from two antiparallel strands

The knowledge of dimensions, relevant for twist knots allows one also to solve an even simpler problem: of 2-component knots from the series $(2p)^2_1$ with inverse orientation, i.e. $2_1^1$, $4_1^1(v1)$, $6_1^1(v2)$, . . . in notation of [43]. As ordinary braids they are increasingly complicated – the number of strands grows typically as $2p$, and the a posteriori very simple example of $6_1^1$ would require a 6-strand analysis. If we instead use the technique, just applied to twist knots, the story gets nearly trivial. Dimensions $v$ in this case can be just taken from the set $v_i^*$, with two factors of $[N]$ thrown away (and also we change $p$ for $2p$ to simplify some formulas).

The link diagram and associated pattern of $2p$ Seifert cycles, obtained when all the vertices are black, look as follows:

From this picture it is clear that the cycle diagram for, say, $p = 2$, is

\[
\begin{array}{cccccc}
3 & 2 & 1 & N^3(N-1) & N^2(N-1)^2 & N(N-1)^3 \\
3 & 2 & 1 & N^3(N-1) & N^2(N-1)^2 & N(N-1)^3 \\
4 & 2 & 2 & N^4 & N(N-1)(N^2 - 3N + 4) \\
3 & 2 & 1 & N^3(N-1) & N^2(N-1)^2 & N(N-1)^3 \\
3 & 2 & 1 & N^3(N-1) & N^2(N-1)^2 & N(N-1)^3 \\
3 & 2 & 1 & N^3(N-1) & N^2(N-1)^2 & N(N-1)^3 \\
\end{array}
\]

The right table lists the classical dimensions of vector spaces at the $2^{2p}$ vertices of the hypercube. As usual for antiparallel braids the pattern is absolutely regular with the single exception in the box. Accordingly the table
of quantum dimensions $v$ is

$$
[N] \times \left( \begin{array}{ccc}
[N]^2[N-1] & [N][N-1]^2 & [N-1]^3 \\
[N]^2[N-1] & [N][N-1]^2 & [N-1]^3 \\
[N]^2[N-1] & [N][N-1]^2 & [N-1]^3 \\
[N]^3 & [N][N-1]^2 & [N-1]^3 \\
\end{array} \right) \left[ N-1 \right] \cdot Y_1
$$

where we took the common factor $[N]$ away – so that these $v$ generate reduced primary polynomial, as everywhere in this paper. For arbitrary $p$ the two entries of the central line are $[N]^{2p-1}$ and $[N-1] \cdot Y_{2p-1}$.

Thus the primary polynomial for given $p$ is just

$$
\mathcal{P}_r^{(2p)(v1)} = q^{2p(N-1)} \left( \sum_{j=0}^{2p-1} C_{2p}^j [N]^{2p-j-1}[N-1]^j \cdot (qT)^j + [N-1]Y_{2p-1} \cdot (qT)^{2p} \right)
$$

(9.6)

where

$$
Y_{2p-1} = [2] + \sum_{j=0}^{p-2} [N-1]^{2j+1}[N-2]
$$

(9.7)

Minimization procedure, i.e. evaluation of cohomologies gets clear from several examples.

9.2.1 $p = 1$: the Hopf link $2_1^2$

$$
q^{2-2N}\mathcal{P}_r^{4(v1)} = [N] + 2qT[N-1] + [N-1] \cdot \left[ 2 \right] \cdot (qT)^2 = q^{1-N} + q[N-1](1 + 2T + T^2) + q^3[N-1]T^2
$$

(9.8)

The only tricks here are to reduce $[N]$ to $[N-1]$ via the usual $[N] = q[N-1] + q^{1-N}$ and divide the contribution from $Y_1$ into two pieces. This is the end of the story: we throw away the underlined cohomologically trivial piece and obtain the answer (5.20). Unreduced case requires this time just an additional multiplication by $[N]$, exactly like in (5.20). Thus, once again:

$$
\mathcal{P}_r^{22} = q^{N-1} \left( 1 + q^{N+2}N^2[N-1] \right)
$$

(9.9)

9.2.2 $p = 2$: the Solomon link in opposite orientation $4_1^2(v1)$

$$
q^{4-4N}\mathcal{P}_r^{4(v1)} = [N]^3 + 4qT[N]^2[N-1] + 6(qT)^2[N][N-1]^2 + 4(qT)^3[N-1]^3 + [N-1] \left( \left[ N-1 \right][N-2] + [2] \right) (qT)^4
$$

$$
= q^3[N-1]^3(1 + 4T + 6T^2 + 4T^3) + q^{3-N}[N-1]^3(3 + 8T + 6T^2) + q^{3-2N}[N-1](3 + 4T) + q^{3-N} + q^4T^4[N-1]Y_3 \sim q^3T^3[N-1]^3 + q^{3-N}T^2[N-1]^2 + q^{3-2N}T[N-1] + q^{3-N} + q^4T^4[N-1]^2
$$

So far we reduced all $[N]$ to $[N-1]$ and eliminated cohomologically trivial factors. Now we pick up two terms and reduce $[N-1]$ to $[N-2]$ with the help of $[N-1] = q[N-2] + q^{2-N}$:

$$
q^3T^3[N-1]^3 + q^4T^4[N-1]^2[N-2] = q^3T^3[N-1]^2 \left( [N-1] + q[N-2]T \right) \sim q^{5-N}T^3[N-1]^2
$$

(9.10)
Now we combine this new term with the next one:

$$q^{5-N}T^3[N-1]^2 + q^{3-N}T^2[N-1]^2 = q^{3-N}T^2(1 + q^2T)[N-1]^2 \sim$$

$$q^{3-N}T^2[N-1]\left(q^{2-N} + q^N T\right) = q^{5-2N}[N-1]T^2 + q^3T^3[N-1]$$

(9.11)

Now the first of these new terms is combined with the next one in the original expression:

$$q^{5-2N}[N-1]T^2 + q^{3-2N}T[N-1] \sim q^{3-2N}T\left(q^{2-N} + q^N T\right) = q^{5-3N}T + q^{3-N}T^2$$

(9.12)

while the second one — with a part of the remaining piece from \(Y_3\), by splitting \([2] = q + q^{-1}\):

$$q^3T^3[N-1] + q^4T^4[N-1] \cdot q^{-1} = q^3T^3[N-1](1 + T) \sim 0$$

(9.13)

What remains are the three items in boxes and one last fragment of \(Y_3\), associated with the piece of \([2]\), which was also boxed. Putting all the four pieces together, we get:

$$\mathcal{P}_5^{(v_1)} = q^{4N-4}\left(q^{3-3N} + q^{5-N}T + q^{3-N}T^2 + q^5T^4[N-1]\right) =$$

$$q^{N-1}\left(1 + q^2T + q^3N^2 + q^{3N+2}T^4[N-1]\right)$$

(9.14)

what reproduces (6.122) — in fact, by a considerably simpler computation. It is trivial to make the necessary corrections in unreduced case and get

$$\mathcal{P}_5^{(v_1)} = q^{4N-4}\left(q^{3-3N}[N] + (q^{4-3N}T + q^{4-N}T^2)[N-1] + q^5T^4[N][N-1]\right) =$$

$$q^{N-1}\left([N] + qT(1 + q^2N)T[N-1] + q^{3N+2}T^4[N][N-1]\right)$$

(9.15)

again in agreement with (6.122) and [43].

9.2.3 \(p = 3\): the 2-component link \(6^2_1(v_2)\) or \(L6a5\)

$$q^{6-6N}\mathcal{P}_5^{(v_1)} = [N]^{5} + 6qT[N]^{4}[N-1] + 15(qT)^2[N][N-1]^{2} + 20(qT)^3[N][N-1]^{3} +$$

$$+15(1 + 6T + 15T^2 + 20T^3 + 15T^4 + 6T^5) + q^{5-N}[N-1]^{4}(5 + 24T + 45T^2 + 40T^3 + 15T^4) +$$

$$+q^{5-2N}[N-1]^{3}(10 + 36T + 45T^2 + 20T^3) + q^{5-3N}[N-1]^{2}(10 + 24T + 15T^2) +$$

$$+q^{5-4N}[N-1](5 + 6T) + q^{5-3N} + q^{3}T^3[N-1]Y_5 \sim$$

$$\sim q^{5}T^{5}[N-1]^{5} + q^{5-N}T^{4}[N-1]^{4} + q^{5-2N}T^{3}[N-1]^{3} + q^{5-3N}T^{2}[N-1]^{2} + q^{5-4N}T[N-1] +$$

$$+q^{6}T^{6}\left([N-1]^{4}[N-2] + [N-1]^{2}[N-2] + [2][N-1]\right)$$

Now we pick up the first items from the last two lines:

$$q^{5}T^{5}[N-1]^{5} + q^{6}T^{6}[N-1]^{4}[N-2] = q^{5}T^{5}[N-1]^{4}\left([N-1] + qT[N-2]\right) \sim q^{7-N}T^{5}[N-1]^{4}$$

(9.16)

Combine this with the second item of the first line:

$$q^{7-N}T^{5}[N-1]^{4} + q^{5-N}T^{4}[N-1]^{4} = q^{5-N}T^{4}(1 + q^2T)[N-1]^{4} \sim$$

$$\sim q^{5-N}T^{4}[N-1]^{3}\left(q^{2-N} + q^{N}T\right) = q^{7-2N}T^{4}[N-1]^{3} + q^{6}T^{5}[N-1]^{3}$$

(9.17)

We get two terms, and their fate is different. The second is combined with the second term from \(Y_5\):

$$q^{5}T^{5}[N-1]^{3} + q^{6}T^{6}[N-1]^{2}[N-2] = q^{5}T^{5}[N-1]^{2}\left([N-1] + qT[N-2]\right) \sim q^{7-N}[N-1]^{2}T^{5}$$

(9.18)
while the first one is combined with the third from the first line to provide
\[ q^{7-2N}T^4|N-1|^3 + q^{5-2N}T^3|N-1|^3 = q^{5-2N}T^3(1 + q^2T)|N-1|^3 \sim \\
q^{5-3N}T^3|N-1|^2 \left( q^{2-N} + q^NT \right) = q^{7-3N}T^3|N-1|^2 + q^{5-N}|N-1|^2T^4 \]

(9.19)

Now we reached the next level, at which we have already four items – they are now all in different places, and for convenience we underlined all of them. Of course, they nicely match:
\[ q^{5-3N}T^2|N-1| + q^{7-N}|N-1|^2T^5 + q^{7-3N}T^3|N-1|^2 + q^{5-N}|N-1|^2T^4 = \\
= q^{5-3N}|N-1|^2(1 + q^2T) \left( q^2T^2 + q^2N^T \right) \sim \\
\sim q^{5-3N} \left( T^2 + q^2N^{-1}T \right) |N-1| \left( q^{2-N} + q^NT \right) = \left( q^{7-4N}T^2 + q^{5-2N}T^3 + q^{7-2N}T^4 + 2q^5T^5 \right) |N-1| \]

(9.20)

To this one should a couple of terms linear in \([N-1]\), underlined twice in original expression:
\[ \left( q^{7-4N}T^2 + q^{5-2N}T^3 + q^{7-2N}T^4 + 2q^5T^5 \right) |N-1| + q^{5-4N}T|N-1| + q^6T^6|N-1| = \\
= q^{5-4N}T|N-1| \left( 1 + q^2T + q^2N^T + q^{2N+2}T^3 + 2q^{4N}T^4 + q^{4N}T^5 \right) + q^7T^6|N-1| \sim \\
\sim q^{5-4N} \left( 1 + q^2N^T \right) |N-1| + \left( q^7T^6|N-1| \right) \sim q^{5-4N} \left( 1 + q^2N^T \right) \left( q^{2-N} + q^NT \right) + q^7T^6|N-1| \]

Collecting all the boxed terms we get:
\[ \mathcal{P}^{-1}_{61} = q^{6N}q^{-6} \left\{ q^{5-5N} + q^{5-4N} \left( 1 + q^2N^T \right) \left( q^{2-N} + q^NT \right) + q^7T^6|N-1| \right\} = \\
= q^{-1} \left\{ 1 + \left( q^N + q^{3N}T \right) \left( q^{2-N} + q^NT \right) + q^{5N+2}T^6|N-1| \right\} = \\
= q^{-1} \left\{ 1 + q^2T + q^2N^T + q^{2N+2}T^3 + q^{4N}T^4 + q^{5N+2}T^6|N-1| \right\} \]

(9.21)

and
\[ \mathcal{P}^{-1}_{62} = q^{N} \left\{ [N] + \left( q^N + q^{3N}T \right) \left( q^{1-N} + q^{N+1}T \right) |N-1| + q^{5N+2}T^6|N-1| \right\} = \\
= q^{-1} \left\{ [N] + \left( qT + q^{2N+1}T^2 + q^{2N+3}T^3 + q^{4N+1}T^4 \right) |N-1| + q^{5N+2}T^6|N-1| \right\} \]

(9.22)

These answers are in accordance with [43].

9.3 The 3-component link \(L6a5\) \((6_1^1(v1))\) of [43]

The link diagram \(L6a5\) is

Orientation of the central circle is clockwise, and counter-clockwise for the other four – so that the pattern of the main Seifert cycles (when all vertices are black) is like in the picture on the right.
Therefore the cycle diagram is

\( (5) \rightarrow 6 \times (4) \rightarrow 15 \times (3) \rightarrow 20 \times (2) \rightarrow 3 \times (3) + 12 \times (1) \rightarrow 6 \times (2) \rightarrow (3) \)

and classical dimensions at hypercube vertices –

\[
N^5 \rightarrow 6 \times N^4(N - 1) \rightarrow 15 \times N^3(N - 1)^2 \rightarrow 20 \times N^2(N - 1)^3 \rightarrow 3 \times N^2(N - 1)(N^2 - 3N + 4) + 12 \times N(N - 1)^4 \rightarrow 6 \times (N - 1)^2(N^2 - 3N + 4) \rightarrow N(N - 1)(N^3 - 5N^2 + 14N - 12)
\]

In the second line we easily recognize factors, which are classical values of \( Y_5 = [N - 1][N - 2] + [2] \), the factor in the third line is also straightforward to quantize:

\[
Z = [N - 1][N - 2]^2 + [2]^2[N - 1] + [2][N - 2]
\] (9.23)

Thus the primary reduced polynomial is

\[
q^{6-6N} \mathcal{P}_r = [N]^4 + 6[N]^3[N - 1] \cdot (qT) + 15[N]^2[N - 1]^2 \cdot (qT)^2 + 20[N][N - 1]^3 \cdot (qT)^3 +
\]

\[
+ 3(N)[N - 1]([N - 1][N - 2] + [2]) + 12[N - 1]^4 \cdot (qT)^4 + 6[N - 1]^2 ([N - 1][N - 2] + [2]) \cdot (qT)^5 +
\]

\[
+ [N - 1]([N - 1][N - 2]^2 + [2]^2[N - 1] + [2][N - 2]) \cdot (qT)^6
\] (9.24)

It is easy to check that this quantization rule indeed properly reproduces HOMFLY polynomial at \( T = -1 \), in particular, at \( N = 2 \) we obtain the right expression for Jones polynomial:

\[
q^{14} - q^{12} + 3q^{10} - q^8 + 3q^6 - 2q^4 + q^2
\] (9.25)

Evaluation of KR polynomial is now straightforward.

**Level 4.** Substitute all \([N]\) by \( q[N - 1] + q^{1-N} \) and \( T \)-reduce whatever possible in all the coefficients:

\[
q^4[N - 1]^4 \left( 1 + 6T + 15T^2 + 20T^3 + 12T^4 \right) + q^{4-N}[N - 1]^3 \left( 4 + 18T + 30T^2 + 20T^3 \right) +
\]

\[
+ q^{4-2N}[N - 1]^2 \left( 6 + 18T + 15T^2 \right) + q^{4-3N}[N - 1] \left( 4 + 6T \right) + q^{4-4N}
\]

\[
+ q^5T^4[N - 1]^3[N - 2] \left( 3 + 6T \right) + 3q^{5-N}T^4[N - 1]^2[N - 2] + q^{6}T^6[N - 1]^2[N - 2]^2 +
\]

\[
+ q^7T^4[N - 1]^2(3[2] + 6[2]T + [2]^2T^2) + q^8T^6[2][N - 1][N - 2] + 3q^{5-N}T^4[2][N - 1] \sim
\]

\[
\sim 2q^4T^4[N - 1]^4 + 3q^5T^5[N - 1]^3[N - 2] + q^{6}T^6[N - 1]^2[N - 2]^2 +
\]

\[
+ 4q^{4-N}T^3[N - 1]^3 + 3q^{5-N}T^4[N - 1]^2[N - 2] +
\]

\[
+ 3q^{4-2N}T^2[N - 1]^2 + q^{5-N}[2] \left( 3 + 6T \right) [N - 1]^2 + q^{6}T^6[2][N - 1][N - 2] +
\]

\[
+ 2q^{4-3N}T[N - 1] + 3q^{5-N}T^4[2][N - 1] + q^{4-4N}
\] (9.26)

In the first line substitute

\[
2[N - 1]^2 + 3qT[N - 1][N - 2] + q^2T^2[N - 2]^2 \sim q^{2-N}(2[N - 1] + qT[N - 2])
\] (9.27)

and add the result to the content of the second line:

\[
q^4T^4[N - 1]^2 \cdot q^{2-N}(2[N - 1] + qT[N - 2]) + 4q^{4-N}T^3[N - 1]^3 + 3q^{5-N}T^4[N - 1]^2[N - 2] =
\]

\[
= q^{4-N}T^3[N - 1]^2 \left( 4[N - 1] + 2q^2T[N - 1] + 3qT[N - 2] + q^3T^2[N - 2] \right)
\] (9.28)

Thus we eliminated everything at the level 4.

**Level 3:**
Now, in (9.28) substitute \([N-1]\) by \(q[N-2] + q^2 - N\) and again eliminate cohomologically trivial combinations:

\[
q^{4-N}T^3[N-1]^2 \left( q[N-2](4 + 3T) + q^3T[N-2](2 + T) + 4q^{2-N} + 2q^{3-N}T \right) \sim \\
\sim q^{4-N}T^3[N-1]^2 \left( 2q^{2-N} + (q[N-2] + 2q^{2-N})(1 + q^2T) \right) \sim \\
\sim 2q^{6-2N}T^3[N-1]^2 + q^{4-N}T^3[N-1](q[N-2] + 2q^{2-N})(q^2 - N + q^2T) \tag{9.29}
\]

where at the last step we substituted \((1 + q^2T)[N-1] \sim q^2 - N + q^2T\). The result belongs to levels 2 and 1: the primary polynomial is currently reduced to

\[
2q^{6-2N}T^3[N-1]^2 + q^{4-N}T^3[N-1](q[N-2] + 2q^{2-N}) \tag{9.30}
\]

\textbf{Level 2:}

In the first line we substitute one of the factors \([N-1]\) by \(q[N-2] + q^2 - N\), and obtain:

\[
q^{4-N}T + [N-1][N-2] \left( 3q^{5-2N}T^2(1 + q^2T) + q^5T^4(1 + 3q[2]T + q[2]T^2 + q^2[2]T^2) \right) + \\
+ [N-1] \left( 2q^{4-3N}T + 3q^{6-3N}T^2 + 4q^{8-3N}T^3 + 3q^{5-N}T^4[2] + 2q^{6-N}T^4 + 3q^{7-N}[2]T^5 + q^{8-N}[2]T^6 \right) \tag{9.31}
\]

In the underlined bracket we have:

\[
1 + 3q[2]T + q[2]T^2 + q^2[2]T^2 = (1 + T)(1 + 2T) + 3q^2T(1 + T) + q^4T^2 \sim q^4T^2 \tag{9.32}
\]

The remaining piece of the first line reduces to a contribution to the second line:

\[
[N-1][N-2] \cdot 3q^{5-2N}T^2(1 + q^2T) \sim 3q^{5-2N}T^2 \left( q^{3-N} + q^{N-1}T \right)[N-1] \tag{9.33}
\]

Thus at the first level we obtain

\[
q^{4-3N}T[N-1] \left( 2 + 3q^2T + 3q^4T + 4q^4T^2 \right) + q^{4-N}T^3[N-1] \left( 3 + (3q[2] + 2q^2T) + 3q^3[2]T^2 + q^4[2]T^3 \right) \tag{9.34}
\]

\textbf{Level 1:}

In the first bracket we have:

\[
2 + 3q^2T + 3q^4T + 4q^4T^2 \sim 2 + q^2T + q^4T^2 = (1 + q^2T)(2 + q^2T) \tag{9.35}
\]

and in the second one –

\[
3 + (3q[2] + 2q^2T) + 3q^3[2]T^2 + q^4[2]T^3 = \\
= 3(1 + T) + q^2T(3 + (2 + T)(1 + T) + 2q^4T(1 + T) + q^4T^2(1 + q^2T) \sim 3q^2T + q^4T^2(1 + q^2T) \tag{9.36}
\]

so that the full contribution from the first level to reduced KR polynomial is

\[
3q^{6-N}T^4[N-1] + \left( q^{4-3N}T(2 + q^2T) + q^{8-N}T^5 \right) \left( q^{3-N} + q^N T \right) \tag{9.37}
\]

and, adding the two boxed items, obtained at the previous steps, we finally obtain:

\[
P_{3}^{2(N+1)} = q^{6-N} \left\{ q^{4-4N} + \\
+ \left( q^{6-N}T(2 + q^2T) + q^{10-2N}T^5 \right) \left( 1 + q^{2N-2}T \right) + \left( q^{6-N}T^4[N-1] + q^9T^6[N-1][N-2] \right) \right\} = \tag{9.38}
\]

129
for reduced KR polynomial. As usual, to obtain unreduced KR polynomial, we substitute the underlined bracket by $q^{-1}(1 + q^{2\mathcal{N}})\mathcal{N} - 1]$, and multiply all other terms by $\mathcal{N}$:

$$
\mathcal{P}^{6(\text{e1})} = q^{6N-6} \left\{ \frac{1}{4} - 4N \mathcal{N} + (q^{5-4N}T(2 + q^2T) + q^{9-2N}T^5) \right\} (1 + q^{2\mathcal{N}})\mathcal{N} - 1] + 3q^{6N-6}T^4\mathcal{N} - 1] + q^{9T6}\mathcal{N} - 1]\mathcal{N} - 1] - 2]\right) =
$$

$$
= q^{2N-2}\mathcal{N} + (2q^{2N-1}T + \left( q^{2N+1} + 2q^{4N-1} \right) T^2 + q^{4N+1}T^3 + q^{4N+3}T^5 + q^{6N+3}T^6) \mathcal{N} - 1] + 3q^{5N}T^4\mathcal{N} - 1] + q^{6N+3}T^6\mathcal{N} - 1]\mathcal{N} - 1] - 2\right) (9.39)
$$

As usual, this is in agreement with the results of [43].

### 9.4 Skein relations for primary polynomials $\mathcal{P}$

Our main idea in this paper is to construct the primary polynomial just in the same way as the fundamental HOMFLY, only substituting $\mathcal{R}$-matrix and its inverse at black and white vertices of the link diagram by

$$
\mathcal{R} = q^{N-1} \left( I + q^{2}\mathcal{N} \pi \right) \quad \text{for} \quad \mathcal{R}
$$

and

$$
\mathcal{R}^- = q^{-N}T^{-1} \left( 2\mathcal{N} + q\mathcal{N} \right) \quad \text{for} \quad \mathcal{R}^-
$$

In order to simplify formulas we write just $I$ instead of more adequate $I \otimes I$. Operator $\pi$ here can be just considered as expressed through the ordinary $\mathcal{R}$-matrix:

$$
\pi = \frac{1}{2} I - q^{-N} \mathcal{R}
$$

and alternatively write

$$
\mathcal{R} = -T \cdot \mathcal{R} + q^{N-1}(1 + T) \cdot I, \quad \mathcal{R}^- = -\frac{1}{T} \cdot \mathcal{R}^{-1} + q^{1-N}(1 + T^{-1}) \cdot I
$$

The fundamental $\mathcal{R}$-matrix satisfies

$$
q^{-N} \mathcal{R} - q^{N} \mathcal{R}^{-1} = q^{1} - q
$$

and this implies skein relations for HOMFLY polynomials. Just in the same way one can get skein relations for the primary polynomials $\mathcal{P}$. Namely, since

$$
\frac{1}{Tq^{N}} \mathcal{R} - Tq^{N} \mathcal{R} = \left( \frac{1}{qT} - qT \right) \cdot I
$$

when calculating the primary polynomial $\mathcal{P}$ we can apply the following identity at any vertex of arbitrary link diagram.

$$
\frac{1}{Tq^{N}} \mathcal{R} - Tq^{N} \mathcal{R} = \left( \frac{1}{qT} - qT \right) \quad \uparrow \uparrow
$$

After that one can proceed, as one usually does with skein relations – iteratively reducing arbitrary link diagram to a collection of unknots, each of them finally substituted by $\mathcal{N}$.

The only thing one should be careful with is that $\mathcal{R}$ and $\mathcal{R}^-$ satisfy a different kind of Reidemeister relations: instead of the second one we have

$$
\mathcal{R} \cdot \mathcal{R}^- = I + \frac{(1 + T)(1 + q^{2}T)}{qT} \cdot \frac{q^{1-N} \mathcal{R} - q^{N-1} \mathcal{R}^-}{qT - \frac{1}{qT}}
$$

(9.47)
the first Reidemeister relation becomes:

\[
\begin{align*}
\begin{array}{c}
\text{Diagram 1} \\
\text{Diagram 2}
\end{array}
\end{align*}
\begin{align*}
= & \quad + \quad \frac{(1+T)(1+q^2T)}{qT(qT-1)} \times \left( q^{1-N} - q^{N-1} \right) \\
= & \quad \times \left( 1 + q^N [N-1](1+T) \right)
\end{align*}
\]

and instead the third one (the Yang-Baxter equation) we have:

\[
R_1 R_2 R_1 - R_2 R_1 R_2 = (T q^2 + 1)(R_1 - R_2)
\]

We will study these deformed skein relations in the subsequent publications.

10 Table of KR polynomials

In this section we collect the answers for KR polynomials. This is essentially the same table as in [43], only we always obtain answers for arbitrary \( N \) and they naturally come in peculiar form, not always seen in [43], thus we can not simply refer to that paper. For links, we present the names according to [79, 80] (the first column) in addition to Rolfsen names used in [43] (the second column). The numbers in figure brackets in the first column label links orientations: there are \( 2^{n-1} \) possible ones for an \( n \)-component link, i.e., 2 ones for a 2-component link and 4 for a 3-component link. However, for some of these orientations may turn topologically equivalent; all links that we consider possess at most two inequivalent orientations labeled as \( v_1 \) and \( v_2 \) in the second column\(^6\). For torus knots and links, we also present the alternative notation \([n, m]\).

\(^6\)Note, that all mutual orientations of Borromean rings are topologically equivalent – thus there is only one orientation, and only one ”version” in terms of [43]: which was named \( v_2 \) in that paper.

Relation to superpolynomials is via the rule (4.1). Remarkably, application of this rule converts somewhat different reduced and unreduced KR polynomials into superpolynomials, which differ by a factor of $[N]$ – exactly as it happens for HOMFLY. Since the rule (4.1) is easy to apply in both directions, this fact actually removes the need to evaluate unreduced KR polynomials ones reduced are known (and vice versa).
11 On properties of morphisms

In this section we briefly summarize what we implicitly learnt about the structure of cut-and-join morphisms, acting along the edges of hypercube.

The main new step in the present paper – as compared to [1] – is explicit construction of the graded vector spaces, standing at the hypercube vertices – we called them \( v \). The spaces of KR complexes are deducible combinations of these spaces (depending on the coloring of the link diagram, i.e. on the initial vertex of the hypercube). As graded spaces they can be represented as polynomials in \( q \), which we further represented as columns of our tables. Differential of KR complex is after that a linear mapping between adjacent columns, which decreases the power of \( q \) by one. Differentials are actually made from morphisms between the particular constituent spaces \( v \) – and if the morphisms are known, the differentials are known as well. The spaces \( v \) in unreduced and reduced cases differ by a common factor of \([N]\), but the difference between morphisms is a little more involved. Differentials are almost one-to-one maps, with some exceptions: elements in the columns which are either mapped to zero or are not the images of the one-to-one maps, belong to cohomologies of the differential. Cohomologies form the KR polynomial.

Coming one step back. in this paper we provided an explicit construction for columns, but differentials – and thus morphisms – are described only at mnemonic level. However, we confirmed a number of properties of the morphisms, advocated in [1].

1) Differentials and thus morphisms have a block form: they preserve decomposition of the spaces \( v \) into a \( m \)-linear \((m \text{ is the number of strands})\) combination of factors \([N − p]\) with \( p = 1, \ldots, m − 1 \) and entire \( N \)-dependence is concentrated in these factors. The fact that \( p \neq 1 \) reflects the slight deviation of morphisms from just elementary shift operations \( α_1 \) and \( β_1 \): the small tails of the spaces \([N − 1]\) are rearranged in a somewhat more complicated way – as was already depicted in [1].

This property allows to make our tables \( N \)-independent: polynomials in columns are further decomposed into poly-linear combinations of above factors and coefficients are smaller polynomials in \( q \), which do not depend on \( N \). At least technically this property provides a distinguished role to the alternated sums in lines: to a constituents of peculiar decomposition of Euler characteristic of the KR complex, i.e. of the HOMFLY polynomial. This decomposition looks like an analogue of decomposition in characters [56, 58], which captures the \( A \)-dependence of HOMFLY and superpolynomials. It is interesting that the decomposition basis for KR polynomials is related, but different – and this effectively eliminates the mysterious \( γ \)-factors [56], appearing in MacDonald decomposition of superpolynomials. Extremely interesting is also an obvious analogy with differential decomposition of [74] – if there is any, this could open a route for generalizations to colored polynomials.

2) Cohomologies possess a clear nested structure: in building them one can hierarchically eliminate the factors \([N − p]\) one after another (there are \( m \) such factors for unreduced and \( m − 1 \) for reduced polynomials, also for \( l \)-component links some ”minor” contributions begin to survive \( l \) steps before the end of reduction).

Technically this property was reflected in our chain of reductions of the tables – from initial one, dictated by decomposition into \( v \)-spaces and describing the primary polynomial \( \mathfrak{P}^C \), to a final one, describing KR polynomial \( \mathcal{P}^C \). This property confirms the suggestion of [1] that morphisms are naturally decomposed into shifts in various \( m \) \((m − 1)\) directions. Another outcome is that the difference between unreduced and reduced polynomials occurs only at the very last reduction – and this explains both the difference between the two and their otherwise-unexpected similarity.

To these two basic observations we add a number of ”smaller” ones, which can still be equally important.

3) Due to projector property \( P^2 = P \) the variety of spaces \( v \) is in fact not as big as the number of different link diagrams. It is in fact nicely ordered by the choice of the strand number \( m \). For example, all the 3-strand diagrams are described by just the 2-parameter set \( v_{n,k} \).

4) At each step of the reduction hierarchy cohomologies are concentrated ”near” one-dimensional diagonals of two-dimensional tables so that the cohomologies are made predominantly from some ”standard blocks”, like ”increasing sequences” and twin pairs with the same powers of \( q \) in adjacent lines \([N − k]\) and \([N − k − 1]\).

This fact seems closely related to the well-known fact, that superpolynomials are ”almost” obtained from HOMFLY by the change of variables, like \( A^2 \rightarrow A^2 T \).

5) In most cases, the cohomologies at each reduction step nearly saturate the alternated sums in lines, but some time extra ”cohomologically trivial” pairs should be added to guarantee the formation of proper twin pairs in adjacent lines.
6) There is usually a non-trivial cohomology in the third column (numeration starts from zero) – for all-black initial vertex this would be order $T^3$.

This rule should be easy to justify from analysis of morphisms: in the third column they still do not deviate too much from the naive shifts $\alpha_i$ and $\beta_i$ and thus can probably be analyzed in enough generality. At the same time, this property is crucial to explaining the breakdown of naive minimality of KR polynomials: in many cases this term has a counterpart with another power of $T$ and could naively be eliminated – but this is forbidden by the actual structure of the morphisms and differentials.

These mnemonic rules, though not fully formalized, provide a very strong support to existence of the KR calculus on the simple lines of [1]. The next three steps: full classification of the spaces $v_i$, explicit construction of morphisms between their combination at adjacent numbers of white vertices (there should be morphisms between $v_n$ and a direct sum of $n$ spaces $v_{n-1}$), and the proof of Reidemeister invariance, should now be within reach.

12 Conclusion

By definition, Khovanov polynomials is the Poincare polynomial of a complex, associated with Abelian quiver, which is made from a hypercube of resolutions of the given link/knot diagram. It is a natural $T$-deformation of HOMFLY polynomial, because the latter turns to be the Euler characteristic of the same complex, which arises from Poincare polynomial at $T = -1$. The hypercube appears in the story whenever the $R$ matrix is split in two parts – thus the choice of the splitting is the starting point of entire construction.

Original Khovanov construction at $N = 2$ uses the splitting associated with geometric resolution, and vector spaces over the vertices of the hypercube are naturally associated with the cycles of resolved link diagram, while morphisms are provided by cut and join operators (see [26] for original presentation and [27, 47] for detailed reviews). Khovanov-Rozansky (KR) construction [30] for arbitrary $N$ substitutes vector spaces by certain cyclic complexes, inspired by matrix-factorization theory, which is rather sophisticated technically (beyond the capacity of modern computers already in rather simple examples) – and the whole construction, while extremely elegant, becomes technically unfeasible. This makes the theory of superpolynomials (a further universalization of KR polynomials) more an artistic guesswork than a solidly based science.

In [1] it was suggested to deduce KR polynomials from a literal generalization of Khovanov construction, returning to the use of vector spaces, associated with cycles of resolved diagrams, without any reference to matrix factorization. Already in [1] it was demonstrated that this is practical approach, and in this paper we provided a lot more evidence to support this claim. Moreover, here we made explicit the underlying splitting of the $R$-matrix and reduce the story to the study of associated ”primary” $T$-deformation $\mathfrak{P}$ of HOMFLY. This stage is calculationally no more complicated than evaluation of ordinary HOMFLY. Afterwards $\mathfrak{P}$ should be substituted by its minimal positive residue $\mathcal{P}$ w.r.t. division over $T+1$ – and this $\mathcal{P}$ is the KR polynomial. The only problem with this approach is certain ambiguity in minimization procedure, and we formulated some mnemonic rules to fix it, at least partly. We are still far from providing a rigorous formulation of this construction, but already at this stage it appears quite powerful technically – providing a list of previously unfeasible examples, including series like 2-, 3- and 4-strand torus knots. All examples from the maximal existing regular list [43] are also reproduced.

At the same time our current presentation sheds certain light on the problem of colored KR polynomials. Fundamental representation is distinguished because the $R$-matrix and its inverse are expressed via a single non-trivial projector (onto representation $[11] \subset [1]^{\otimes 2}$). In colored case things are at least not so simple. It is even possible that a separate deformation parameter can be associated with each item $Q$ in decomposition of representation product $R \otimes R = \oplus Q$.

To conclude and to prevent misunderstanding, we repeat once again that the KR polynomials in this paper are not fully derived on the lines of [1]: most of them are actually chosen from a finite set of choices. Full derivation provides accurate description of morphisms, suggested in [1], and evaluation of their cohomologies – what requires additional work and is left for the future publications. In this paper we just showed what these morphisms should be in each particular case to provide the right answers – and it is made quite clear that they obey strict rules, what provides very strong evidence that they indeed exist. Thus this paper is an important step in sharpening and justification of the claims in [1] and, most important, in providing a working tool for evaluation of arbitrary KR polynomials in the fundamental representation.
