DLC
California Mastitis Test (CMT)

ABSTRACT

The study was conducted to determine the effect of subclinical mastitis (SCM) and clinical mastitis (CM) on haemato-biochemical parameters and milk leukocyte count of crossbred cattle. Milk and blood samples were collected from 20 healthy, 223 SCM and 47 CM affected animals from Kolar and Chikkaballapur districts of Karnataka state, India. The SCM were diagnosed by California Mastitis Test (CMT) and electrical conductivity (EC) of milk. Blood and milk of mastitis infected crossbred cattle were analyzed for haemato-biochemical parameters and milk leukocyte count. Haematology showed significant increase in TLC in crossbred cows affected with mastitis. Significantly (P< 0.05) lower average values of TEC, Hb and PCV were observed in SCM infected animals, however no significant change were observed in values of CM infected than healthy animals. Differential leucocytic count (DLC) revealed higher granulocytes and lymphopenia in mastitis infected animals. Biochemical estimation revealed significantly (P< 0.05) higher average values of Ca, P, Na, Cl, and K in mastitis infected compared with healthy animals however, no significant (P> 0.05) change was observed in Mg and ALT levels. AST and TP values were significantly increased in SCM infected compared to healthy animals however, no significant change were observed in CM infected animals. Macrophage and...
lymphocyte count showed significant decrease, however the total leukocyte and neutrophil count in milk were significantly increased in mastitis affected animals. The changes in haematobiochemical parameters and milk leukocyte count are important indicators of the physiological or pathological state (mastitis) of the animal.

1 Introduction

Mastitis remains a serious concern to dairy farmers till date. Mastitis is an inflammation of the mammary gland of dairy cattle associated with physical, bacteriological and pathological alterations in milk and tissue of mammary gland. Blood & Radostits (1989) defined mastitis as a disease characterized by the presence of significantly increased leucocytes content in the milk from affected gland.

High yielding milch animals, especially crossbred and exotic breeds are more prone for mastitis with infection being higher in late lactation in comparison to the first. Crossbreeding of cattle for better milk production is also a primary cause for mastitis due to changes in position, size and rapid milk excretion from mammary gland causing stressful condition leading to udder infection (Gibbons et al., 1970).

Subclinical and clinical forms of mastitis occur in dairy cattle where the subclinical mastitis usually leads to the clinical form even though the association between both types is not clear in larger group of animals (Rolands & Booth, 1988). Subclinical mastitis is a neglected disease by dairy farmers even though it causes a huge economic loss to the dairy industry. Disruption of the blood-milk barrier in addition to decreased production and secretion from udder epithelial cells which causes a change in milk composition in mastitic animals. The evaluation of the haemato-biochemical changes and alterations in milk leukocyte content of mastitis affected crossbred cows was undertaken in the present study.

2 Materials and Methods

Blood samples were collected from jugular vein of 20 healthy, 223 SCM and 47 CM affected crossbred cattle from Kolar and Chikkaballapur districts of Karnataka state, India in heparinised mineral free (15-20ml) vials and disodium EDTA (2-3ml) vials. Blood samples were transported to the laboratory within one hour in a thermo flask with ice & then fresh blood was analyzed for Hb, PCV, TEC, TLC, ESR and DLC by using fully automated hematology analyzer (Mindray, BC-1800). The serum separated from blood was analyzed for ALT, AST, Ca, Cl, K, Mg, Na, P and TP by using fully automated biochemical analyzer (Thermo scientific KONELAB 20).

The milk samples collected were subjected for California Mastitis test (CMT), Somatic cell count (SCC) and electrical conductivity (EC) measurement. EC was determined by using Milk checker (Eisai Co. Ltd. and Oriental instruments Ltd., Tokyo. Japan) and a value more than 6.5 mS/cm were considered as positive for SCM (Swarup et al., 1989). Milk samples for differential leukocyte count and somatic cell count were collected under aseptic conditions in sterile containers. Milk total somatic cell and differential leukocyte count were estimated according to general principle of Prescott and Breed method as detailed by Schalm et al. (1971) and a value > 5.00 Lakhs/ml of milk was taken as criteria to declare the milk or animal as subclinically mastitic or infected. The data obtained from the study was analyzed by one way analysis of variance (ANOVA) test using Graph Pad Prism version 5 for windows.

3 Results and Discussion

Haematology of animals revealed significantly (P< 0.05) higher average values of ESR and TLC in mastitis infected than healthy animals. Significantly (P< 0.05) lower average values of TEC, Hb and PCV were observed in SCM infected animals, however no significant change were observed in values of CM infected than healthy animals. TLC revealed significantly higher granulocytes and lymphopenia in mastitis infected animals (Table 1). Biochemical estimation revealed significantly (P< 0.05) higher average values of Ca, P, Na, Cl, and K in mastitis infected compared with healthy animals however, no significant (P> 0.05) change was observed in Mg and ALT levels. AST and TP values were significantly increased in SCM infected compared to healthy animals however, no significant change were observed in CM infected animals (Table 2). The total milk leukocytes and neutrophils were significantly higher, while lymphocytes and macrophages population were significantly lower in mastitis infected animals (Table 3). Significant increase in EC of milk from SCM and CM infected animals were observed in comparison to healthy animals.

Hb, TEC and PCV level of SCM cows showed significant decrease in comparison to healthy animals. These observations are in accordance with Zaki et al. (2010) those who recorded significant reduction in RBC, Hb and PCV values leading to anaemia in animals affected with mastitis. No significant changes were observed in Hb and TEC level of CM affected animals as opposed to healthy cows. No significant trends in PCV and Hb in mastitic cases were observed by Sischo et al. (1997) which is in line with the findings of this study.
Higher leukocyte and granulocyte count was recorded in the present study in clinical as well as subclinical mastitis affected animals. However lymphocyte count was observed to be significantly lower in mastitic cases. Zaki et al. (2004) in serum of mastitic cows. However, reduced TP values in mastitic cases were observed by Zaki et al. (2008). This may be attributed to the decreased albumin levels after the immune response to the udder infection (Singh, 2000). Serum calcium level of the SCM and CM infected animals were significantly (P< 0.05) higher than the healthy animals which is similar to our findings. Singh et al. (2010) observed a significant rise was observed in CM infected animals. Higher levels of globulin and total protein was reported by Dwivedi et al. (2004) in serum of mastitic cows. However, reduced TP values in mastitic cases were observed by Zaki et al. (2008). This may be attributed to the decreased albumin levels after the immune response to the udder infection (Singh, 2000). Serum calcium level of the SCM and CM infected animals were significantly (P< 0.05) higher than the healthy animals which is attributed to the reduced milk production in affected animals which causes decreased Ca excretion in milk (Wegner & Stull, 1978). Singh et al. (2014) reported higher plasma levels of Ca to the present study Zaki et al. (2010) observed a reduction in the Ca values in the infected animals.

Table 1 Haematological parameters of control and mastitic crossbred cows.

| Sl. No. | Parameter                  | Control (n=20) | Mastitis (n=47) |
|--------|---------------------------|---------------|-----------------|
| 1      | Hb g/Dl                   | 10.50±0.29a   | 9.03±0.01b      |
| 2      | PCV %                     | 31.07±0.44a   | 28.05±0.16b     |
| 3      | TEC x10³/µL               | 7.22±0.17b    | 6.91±0.04b      |
| 4      | TLC x10³/µL               | 6.86±0.22a    | 10.13±0.11b     |
| 5      | Granulocyte (%)           | 35.74±0.77a   | 65.16±0.21b     |
| 6      | Lymphocyte (%)            | 60.52±0.65a   | 37.2±0.28a      |
| 7      | Monocyte (%)              | 3.75±0.42a    | 4.12±0.12a      |
| 8      | ESR mm/2hrs               | 1.15±0.02a    | 1.97±0.02b      |

Mean ±SE values given for each treatments, Means marked with different letters are significantly differ (P< 0.05) in a row.

Table 2 Biochemical parameters of control and crossbred cows.

| Sl. No. | Parameter          | Control (n=20) | Mastitis (n=47) |
|--------|--------------------|---------------|-----------------|
| 1      | ALT U/L            | 10.02±0.37a   | 10.11±0.21b     |
| 2      | AST U/L            | 75.41±2.28a   | 120.29±1.08b    |
| 3      | TP g/dL            | 7.22±0.14a    | 7.80±0.03b      |
| 4      | Ca mg/dL           | 9.37±0.25a    | 13.04±0.08b     |
| 5      | P mg/dL            | 6.49±0.12a    | 4.85±0.04b      |
| 6      | Mg mg/dL           | 2.18±0.11a    | 2.26±0.03b      |
| 7      | CI mEq/L           | 99.20±1.30a   | 88.62±0.32b     |

| 6      | OTHERS %           | 2.43±0.22a    | 11.03±0.21b     |

Mean ±SE values given for each treatments, Means marked with different letters are significantly differ (P< 0.05) in a row.
Average value of phosphorous of the healthy animals were significantly ($P < 0.05$) higher than the SCM and CM infected animals which could be attributed to its higher secretion in milk, due to injury to the udder wall resulting in increased loss in milk which is in accordance with the observation of Dwivedi et al. (2004) and Siddique et al. (2015).

In the present study no significant change in magnesium levels were recorded in mastitis affected animals which was in agreement with the findings of Dwivedi et al. (2004) and Yildiz & Kaygusuzolu (2005). However, higher levels in serum Mg of buffaloes suffering from acute mastitis were reported by Singh (1999) and decreased serum Mg levels were recorded by Siddique et al. (2015).

Sodium, chloride and Potassium levels of the SCM and CM infected animals were significantly ($P < 0.05$) higher than the healthy animals. An increased level of sodium and potassium in serum of mastitic cases were observed which was in line with the findings of Atroshi et al. (1996). This was attributed to the reduced milk yield during mastitis which elevates the level of sodium, potassium and chloride in blood due to minimal loss from the mastitis affected animal. Increased levels of plasma K in buffaloes suffering from mastitis was also reported by Singh (1999). The highly significant increases detected in AST values of SCM are in line with the reports of Bayumi et al. (2005) and Chandrasekaran et al. (2015) which could be due to stressful conditions.

The total milk leukocytes (Figure 1 & 2) and granulocytes were significantly higher, while lymphocytes and macrophages population were significantly lower in mastitis infected animals indicating mammary gland infection. One of the most ideal biomarkers in mastitis is milk leukocyte count. In the present study, a higher level of milk leukocytes is indicative of the immune response caused by the microorganisms in the mastitis affected mammary gland (Djabri et al., 2002; Gargouri et al., 2008). These results are in line with the findings of Hussain et al., 2012 and Hussain et al., 2013. The colonization of mammary glands by pathogenic micro-organisms results in
a series of events which leads to major alterations of milk compositions secreted from cells. Therefore CMT (Figure 4) is a suitable measure for use on large scale monitoring programs.

Significant increase in EC of milk from SCM and CM (Figure 3) infected animals were observed compared to healthy animals. This is in accordance with the reports of Sripad et al. (2013). The increase in EC milk of mastitis animals could be due to elevated levels of ions such as sodium, potassium, calcium and chloride during mammary gland inflammation.

In conclusion, the changes in haemato-biochemical parameters and milk leukocyte count can be used as important indicators of the physiological or pathological state (mastitis) of the animal. In addition, we conclude that CMT, EC and SCC is ideal for early detection of subclinically infected quarters and aids in the selection of dairy animals for either segregation or therapy.
