Quivers and the cohomology of homogeneous vector bundles

Giorgio Ottaviani  Elena Rubei

Abstract

We describe the cohomology groups of a homogeneous vector bundle $E$ on any Hermitian symmetric variety $X = G/P$ of ADE type as the cohomology of a complex explicitly described. The main tool is the equivalence between the category of homogeneous bundles and the category of representations of a certain quiver $Q_X$ with relations, whose vertices are the dominant weights of the reductive part of $P$. This equivalence was found in some cases by Bondal, Kapranov and Hille and we find the appropriate relations on any Hermitian symmetric variety.

1 Introduction

The Borel-Weil-Bott theorem computes the cohomology groups of an irreducible homogeneous bundle on a rational homogeneous variety $X$. In this paper we compute the cohomology groups of any homogeneous bundle (including the reducible ones) on a symmetric Hermitian variety of ADE type. This class of varieties includes grassmannians, quadrics of even dimension, spinor varieties, two exceptional cases and products among all of them.

In order to compute the cohomology groups (see Thm. 6.11) we have to describe the homogeneous bundles as representations of a certain quiver $Q_X$. The moduli spaces of such representations give moduli spaces of homogeneous bundles, that are introduced in §7 and seem to have an intrinsic interest.

We describe now with some detail the background of this paper.

Let $X = G/P$ be a rational homogeneous variety. It is known that the category of $G$-homogeneous bundles on $X$ is equivalent to the category $P\text{-mod}$ of representations of $P$, and also to the category $P\text{-mod}$ where $P = \text{Lie} P$ (see for example [B-K]). Since $P$ is not reductive, its representations are difficult to describe. In fact if $E$ is a homogeneous bundle, it has a filtration $0 \subset E_1 \subset \ldots \subset E_k = E$ where $E_i/E_{i-1}$ is irreducible, but the filtration does not split in general.

Let $P = R \cdot N$ be the Levi decomposition, where $R$ is reductive and $N$ is nilpotent. At the level of Lie algebras this amounts to $P = \mathcal{R} \oplus \mathcal{N}$ as vector spaces. Considering $E$ as $R$-module (and hence as $\mathcal{R}$-module) we get the graded bundle $gr E = \bigoplus_i E_i/E_{i-1}$.
The nilpotent radical $\mathcal{N}$ is an $\mathcal{R}$-module itself, with the adjoint action, corresponding to the bundle $\Omega^1_X$. The action of $\mathcal{P}$ over $E$ induces a $G$-equivariant map

$$\theta: \Omega^1_X \otimes gr\,E \rightarrow gr\,E$$

Our first result is that, when $X$ is a Hermitian symmetric variety, a morphism of $\mathcal{R}$-modules $\theta: \Omega^1_X \otimes F \rightarrow F$ is induced by a $\mathcal{P}$-action if and only if $\theta \wedge \theta = 0$ (see Thm. 3.1).

In analogy with [Simp], we call a completely reducible bundle $F$ endowed with such $\theta$ satisfying $\theta \wedge \theta = 0$ a (homogeneous) Higgs bundle. So the category of $G$-homogeneous bundles turns out to be equivalent to the category of Higgs bundles. In the pair $(F, \theta)$, $F$ encodes the discrete part and $\theta$ encodes the continuous part.

By using Bott theorem we can prove that $\text{Hom}(gr\,E \otimes \Omega^1_X, gr\,E)^G$ is isomorphic to $\text{Ext}^1(gr\,E, gr\,E)^G$ (see Thm. 4.3). In this setting a reformulation of Thm. 3.1 implies that the set of $\mathcal{P}$-modules $E$ such that $gr\,E = F$ is in natural bijection with the set of $e \in \text{Ext}^1(F, F)^G$ such that $m(e) = 0$ where $m$ is the quadratic Yoneda morphism $\text{Ext}^1(F, F)^G \rightarrow \text{Ext}^2(F, F)^G$.

Bondal and Kapranov had the remarkable idea that quivers are the appropriate tool to manage $\mathcal{P}$-modules, indeed we state our results in the framework of quivers.

A quiver $Q_X$ is associated to any rational homogeneous variety $X$. The points of $Q_X$ are the dominant weights of $\mathcal{R}$ and the arrows correspond to the weights of $\mathcal{N}$ in the action (*). Bondal, Kapranov [B-K] and Hille [Hi2] proved that the category of $G$-homogeneous bundles on $X$ is equivalent to the category of representations of $Q_X$ with certain relations to be determined (see also [King]). Hille in [Hi2] proved that the relations in $Q_X$ are quadratic if $X$ is Hermitian symmetric and found that the relations of the quiver constructed in [B-K], although essentially corrected, were not properly stated in the case of the Grassmannian of lines in $\mathbb{P}^3$ (see Example 5.11). Then Hille showed that in $Q_{\mathbb{P}^n}$ the relations correspond to the commutativity of all square diagrams. If $X$ is Hermitian symmetric we see that the relations are consequences of the condition $\theta \wedge \theta = 0$. This allows one to extend Hille’s result to $Q_{\mathbb{P}^n}$ (see Cor. 8.5).

The second part of the paper is devoted to the computation of the cohomology. The Borel-Weil-Bott theorem computes the cohomology groups of an irreducible bundle $E$ on $X$. In particular it says that $H^*(E)$ is an irreducible $G$-module. It follows that for any $G$-homogeneous bundle $E$ there is a spectral sequence constructed by the filtration $gr\,E$ abutting to the cohomology groups of $E$. The main problem is that the maps occurring in the spectral sequence, although they are equivariant, are difficult to control. In fact most of the main open problems about rational homogeneous varieties, like the computation of syzygies of their projective embeddings, reduce to the computation of cohomology groups of certain homogeneous bundles (see the recent book [We]).

Assume now that $X$ is Hermitian symmetric of ADE type. Thanks to the Borel-Weil-Bott theorem, and to the results of Kostant in [Ko], we can divide the points of $Q_X$ into several chambers, separated by the hyperplanes containing the singular weights, that we call Bott chambers. We consider the segments connecting any point of $Q_X$ with its mirror images in the adjacent Bott chambers, and we define certain
linear maps $c_i:H^i(grE) \to H^{i+1}(grE)$, by composing the maps associated to the representation of $Q_X$ corresponding to $E$, along these segments. We get a sequence

$$
\ldots \to H^i(grE) \xrightarrow{c_i} H^{i+1}(grE) \xrightarrow{c_{i+1}} \ldots
$$

Our main result (Thm. [6.11]) is that this sequence is a complex and its cohomology (as $G$-module) is the usual cohomology $H^i(X,E)$.

The proof of this result is obtained by comparing the maps $c_i$ with the boundary maps. In the case of projective spaces the computation of $c_i$ can be done quite easily. It is worth remarking that the derived category of homogeneous bundles was described by Kapranov in the last section of [Ka]. The quivers allow one to refine that approach.

It turns out from our proof that the cohomology modules $H^i(E)$ are equipped with a natural filtration

$$0 \subset H^i[1](E) \subset H^i[2](E) \subset \ldots \subset H^i[N](E) = H^i(E)$$

The last part of the paper deals with moduli spaces. There is a notion of semistability of representations of quivers introduced in [King] (see also [Mig]) which is suitable to construct moduli spaces according to Mumford GIT. This notion of semistability turns out to be equivalent to the Mumford-Takemoto semistability of the bundle and we get moduli spaces of $G$-homogeneous semistable bundles with fixed $grE$. More precisely, the choice of an $\mathcal{R}$-module $F$ is equivalent to the choice of a dimension vector $\alpha$ as in [King]. All semistable $P$-modules $E$ such that $grE = F$ are parametrized by a projective moduli space $M_X(\alpha)$. The properties of such moduli spaces probably deserve further study.

Finally we want to mention that some applications of this approach to the case of homogeneous bundles on $P^2$ appear in [O-R].

We thank Laurent Manivel for several helpful comments, and Piotr Pragacz, who advised us to consider the Olver maps in order to make the relations explicit.

## 2 Notation and Preliminaries

In all the paper let $G$ be a semisimple complex Lie group. We fix a Cartan subalgebra $\mathcal{H}$ in $\text{Lie}G$. Let $\Delta = \{\alpha_1, \ldots, \alpha_n\}$ be a fundamental system of simple roots for $\text{Lie}G$. A positive root is a linear combination with nonnegative integral coefficients of the simple roots. The Killing product allows one to identify $\mathcal{H}$ with $\mathcal{H}^\vee$ and thus to define the
Killing product also on $\mathcal{H}^\vee$. Let $\{\lambda_1, \ldots, \lambda_n\}$ be the *fundamental weights* corresponding to $\{\alpha_1, \ldots, \alpha_n\}$, i.e. the elements of $\mathcal{H}^\vee$ such that $\frac{\langle \lambda, \alpha_i \rangle}{\langle \alpha_i, \alpha_i \rangle} = \delta_{ij}$ where $\langle \cdot, \cdot \rangle$ is the Killing product. Let $Z$ be the lattice generated by the fundamental weights. The elements in $Z$ that are linear combination with nonnegative coefficients of the fundamental weights are called the dominant weights for $G$, and they are the maximal weights of the irreducible representations of $\text{Lie}G$. In the ADE case all roots have length $\sqrt{2}$.

For any $W$ representation of $G$ we denote by $W^G$ its invariant part, that is the subspace of $W$ where $G$ acts trivially. If $V$ is an irreducible representation, we denote $W^V := \text{Hom}(V, W)^G \otimes V$.

If $\lambda \in Z$ we denote by $V_\lambda$ the irreducible representation of $G$ with highest weight $\lambda$. In the case $G = \text{SL}(n+1)$ to any $\lambda$ is associated a Young diagram. Precisely if we have $\lambda = \sum_{i=1}^n n_i \lambda_i$, then we set $a_i = \sum_{j \geq i} n_j$ and we get the Young diagram with $a_i$ boxes in the $i$-th row. We use the notation where the first row is the top row. The $n$-uple $a = (a_1, \ldots, a_n)$ is a partition of $\sum a_i$ and it is customary to denote $V_\lambda$ as $S^a V$. In particular $S^2 V = S\text{ym}^2 V$ and $S^{1,1} V = \wedge^2 V$.

Let $X = G/P$ be a rational homogeneous variety, where $P$ is a parabolic subgroup ([Ko], [F-H]). We fix a splitting $\text{Lie}P = \text{Lie}R \oplus \text{Lie}N = \mathcal{R} \oplus \mathcal{N}$, where $\mathcal{R}$ is reductive and $\mathcal{N}$ is the nilpotent radical. A representation of $P$ is completely reducible iff it is trivial on $\mathcal{N}$ (see [Ise] or [Ot]). In this case the representations are determined by their restriction on $\mathcal{R}$.

**Homogeneous vector bundles** The group $G$ is a principal bundle over $X = G/P$ with fiber $P$. Denote by $z$ the point of $X$ which is fixed by $P$, corresponding to the lateral class $P \in G/P$. Any $G$-homogeneous vector bundle $E$ with fiber $E(z)$ over $z$ is induced by this principal bundle via a representation $\rho: P \to \text{GL}(E(z))$. We denote $E = E_{[\rho]}$. Equivalently, $E_{[\rho]}$ can be defined as the quotient $G \times_P E(z)$ of $G \times E(z)$ via the equivalence relation $\sim$ where $(g, v) \sim (g', v')$ iff there exists $p \in P$ such that $g = g'p$ and $v = \rho(p^{-1})v'$.

We denote by $E_\lambda$ the homogeneous bundle corresponding to the irreducible representation of $P$ with maximal weight $\lambda$. Here $\lambda$ belongs to the fundamental Weyl chamber of the reductive part of $P$ (see the beginning os §4).

**Hermitian symmetric varieties** We recall that the tangent bundle of $X$ is defined by the adjoint representation over $\text{Lie}G/\text{Lie}P$. According to Kostant, we say $X$ is a Hermitian symmetric variety if the above adjoint representation is trivial on $\mathcal{N}$. This is equivalent to ask $[\mathcal{N}, \mathcal{N}] = 0$. The Hermitian symmetric varieties were classified by Cartan and their list is well known. They are product of irreducible ones. The irreducible ones are grassmannians, quadrics, spinor varieties, maximal lagrangian grassmannians and two varieties of exceptional type of dimension 16 and 27 (see Thm. 5.12 for the precise list). For a modern treatment see [Ko] or [L-M]. According to the corresponding Dynkin diagram, an irreducible Hermitian symmetric variety is called of type ADE if $G = \text{SL}(m), \text{Spin}(2m), E_6$ or $E_7$. Only odd quadrics and maximal lagrangian grassmannians are left, which are called of type BC. A Hermitian symmetric variety is called of type ADE if it is the product of irreducible Hermitian symmetric varieties of type ADE. Hermitian symmetric varieties of ADE type have two interesting features that we want to underline. The first one is that when $X \subset P(V)$
is a minimal homogeneous embedding, then $V$ has a weight structure which make it isomorphic to the cohomology group $H^*(X, \mathcal{C})$. The second one is that the degree of Schubert cycles can be computed easily from the Hasse quiver, as in next paragraph. The reason why we have to restrict to the ADE type in the computation of cohomology is explained in Lemma 6.4 and Lemma 6.5. In all the irreducible cases we have $Pic(X) = \mathbb{Z}$. Thus on irreducible Hermitian symmetric varieties the first Chern class $c_1(E)$ of a bundle $E$ can be identified with an integer, and the slope is by definition $\mu(E) = c_1(E)/rk(E) \in \mathbb{Q}$. On any Hermitian symmetric variety $X = X_1 \times \ldots \times X_r$ where $X_i$ are irreducible there are several possible choices of slopes. With obvious notations, if $c_1(E) = (c_1^1, \ldots, c_1^r) \in \mathbb{Z}^r$ and $a = (a_1, \ldots, a_r) \in \mathbb{Q}^r$ then we define $\mu_a(E) = \sum c_1^{i}a_i/rk(E) \in \mathbb{Q}$.

It is easy to check (see e.g. [Ram] 5.2) that $\mu_a(E\bigoplus_{n_\lambda}) = \sum n_i\mu_a(E_\lambda)$.

The Hasse quiver Quivers will be recalled in §5. For this paragraph it is enough to know that a quiver is just an oriented graph. If $X$ is a rational homogeneous variety, the cohomology $H^*(X, \mathbb{Z})$ can be organized in a quiver in the following way. Consider the action of a Borel subgroup $B \subset P$ on $X$. Then it is well known that $X$ is divided in a finite union of orbits, their closures are called the Schubert cells and form an additive basis $H^*(X, \mathbb{Z})$. The vertices of the Hasse quiver $\mathcal{H}_X$ are the Schubert cells, we draw an arrow between $X_\lambda \in H^{2p}(X, \mathbb{Z})$ and $X_\mu \in H^{2p+2}(X, \mathbb{Z})$ if $X_\mu \supset X_\lambda$. If $X$ is a Hermitian symmetric variety the additive basis of $H^{2p}(X, \mathbb{Z})$ corresponds to the direct summands of $\Omega^p$. If $X$ is Hermitian symmetric, the degrees of the Schubert cycles in the homogeneous minimal embedding are computed as the number of paths in the Hasse quiver which starts from the corresponding vertex. We learned this fact from L. Manivel (see [LM]).

The filtration of a homogeneous bundle and the functor $gr$ Let $E$ be a homogeneous bundle on an irreducible Hermitian symmetric variety.

We define $grE = \bigoplus_i E_i/E_{i-1}$ for any filtration $0 \subset E_1 \subset \ldots \subset E_k = E$ such that $E_i/E_{i-1}$ is completely reducible. The graded bundle $grE$ does not depend on the filtration, in fact it is given by the restriction of the representation giving $E$ to the reductive part $R$ of $P$.

For example the Euler sequence on $P = P(V)$ tells us that $gr(O(1)_P \otimes V) = O_P \oplus TP$.

The functor $E \mapsto grE$ from $P$-mod to $R$-mod (which in the literature is often denoted as $Ind_P^G$) is exact. It is easy to check the formulas

$$(grE)^* = gr(E^*) \quad gr(E \oplus F) = grE \oplus grF \quad gr(E \otimes F) = grE \otimes grF$$

The spectral sequence abutting to the cohomology The Borel-Weil-Bott theorem describes the cohomology of the irreducible homogeneous bundles $E$. It says that $H^*(E)$ is an irreducible $G$-module. For any homogeneous bundle and for any filtration there is a spectral sequence abutting to the cohomology of the bundle. Precisely, if $grE = \bigoplus_{k=1}^\infty A_k$ as before, we have $E_{p,q}^1 = H^{p+q}(A_{k-p})$ abutting to $E_{p,q}^\infty$ where $H^*(E) = \bigoplus_{p+q=\infty} E_{p,q}$. Thm. 6.11 will give a more efficient way to compute $H^*(E)$.

Yoneda product We recall the Yoneda product on $Ext$ according to [Ex] exer. A3.27. For any homogeneous bundles $E$, $F$ and $K$ there is an equivariant Yoneda
product
\[ \text{Ext}^i(E, F) \otimes \text{Ext}^j(F, K) \to \text{Ext}^{i+j}(E, K) \]
and this product is associative. In particular in the case \( E = F = K \) and \( i = j = 1 \) we get a (non symmetric) bilinear map, whose symmetric part induces a quadratic morphism
\[ \text{Ext}^1(E, E) \to \text{Ext}^2(E, E) \]
In particular, since it preserves the invariant part, it gives
\[ m: \text{Ext}^1(E, E)^G \to \text{Ext}^2(E, E)^G \]

**Tensor product of two irreducible representations** Let \( \lambda \) and \( \nu \) two weights in the fundamental Weyl chamber of a Lie algebra \( K \). The tensor product of the corresponding representations \( V_\lambda \otimes V_\nu \) can be expressed as a sum \( \oplus c_{\lambda\nu\kappa} V_\kappa \) where \( c_{\lambda\nu\kappa} \) are integers (counting the multiplicities). When \( K = \text{LieSL}(n) \) the integers \( c_{\lambda\nu\kappa} \) can be computed by the so called Littlewood-Richardson rule (see [F-H]). A more conceptual algorithm was later conjectured by Weyman and proved by Littelmann in [L]: this algorithm holds for an arbitrary simple Lie groups. Let \( \nu_1 = \nu, \nu_2, \ldots, \nu_k \) be all the weights of \( V_\nu \). Littelmann proves that
\[ V_\lambda \otimes V_\nu = \oplus_{i \in I} V_{\lambda + \nu_i} \tag{1} \]
where \( I \) is a subset of \( \{1, \ldots, k\} \) such that the weights \( \nu_i \) for \( i \in I \) correspond exactly to the standard Young tableaux of the form corresponding to \( \nu \) which are \( \lambda \)-dominant (see [L] for the precise definitions). A particular interesting case is when \( \lambda + \nu_i \) are all dominant for \( i = 1, \ldots, k \), this is true when \( \lambda \gg 0 \). In this case we have the whole decomposition
\[ V_\lambda \otimes V_\nu = \oplus_{i=1}^k V_{\lambda + \nu_i} \]
(see also [F-H] exer. 25.33). Formula (1) above applied to vector bundles gives
\[ E_\lambda \otimes E_\nu = \oplus_{i \in I} E_{\lambda + \nu_i} \]
where all the direct summand in the right side have the same slope (see [Ram] or [Ot]).

### 3 P-mod and the category of Higgs bundles

Let \( X \) be a Hermitian symmetric variety. We recall that \( \mathcal{N} \) is an \( \mathcal{R} \)-module with the adjoint action. Our starting point is the following

**Theorem 3.1** (i) Given a \( \mathcal{P} \)-module \( E \) on \( X \), the action of \( \mathcal{N} \) over \( E \) induces a morphism of \( \mathcal{R} \)-modules
\[ \theta: \mathcal{N} \otimes \text{gr} E \to \text{gr} E \]
such that \( \theta \wedge \theta = 0 \) in \( \text{Hom}(\wedge^2 \mathcal{N} \otimes \text{gr} E, \text{gr} E) \)

(ii) Conversely given an \( \mathcal{R} \)-module \( F \) on \( X \) and a morphism of \( \mathcal{R} \)-modules
\[ \theta: \mathcal{N} \otimes F \to F \]
such that \( \theta \wedge \theta = 0 \) then \( \theta \) extends uniquely to an action of \( \mathcal{P} \) over \( F \), giving a bundle \( E \) such that \( \text{gr} E = F \).
Proof (i) For every \( r \in \mathcal{R}, \ n \in \mathcal{N}, \ f \in F \), since \( E \) is a \( \mathcal{P} \)-module we have

\[
    r \cdot (n \cdot f) = n \cdot (r \cdot f) + [r,n] \cdot f
\]

that is

\[
    r \cdot (\theta(n \otimes f)) = \theta(n \otimes (r \cdot f)) + \theta([r,n] \otimes f) = \theta(r \cdot (n \otimes f))
\]

so that \( \theta \) is \( \mathcal{R} \)-equivariant. Moreover for any \( n_1, n_2 \in \mathcal{N} \)

\[
    \theta \wedge \theta \left( (n_1 \wedge n_2) \otimes f \right) = n_1 \cdot (n_2 \cdot f) - n_2 \cdot (n_1 \cdot f) = [n_1, n_2] \cdot f = 0
\]

because \( [\mathcal{N}, \mathcal{N}] = 0 \) and this is equivalent to \( \theta \wedge \theta = 0 \).

(ii) We have for any \( r + n \in \mathcal{R} \oplus \mathcal{N} = \mathcal{P} \)

\[
    (r + n) \cdot f := r \cdot f + \theta(n \otimes f)
\]

and we have to prove that for any \( p_1, p_2 \in \mathcal{P} = \mathcal{R} \oplus \mathcal{N} \) we have

\[
    [p_1, p_2] \cdot f = p_1 \cdot (p_2 \cdot f) - p_2 \cdot (p_1 \cdot f) \tag{2}
\]

We distinguish three cases.

If \( p_1, p_2 \in \mathcal{R} \) then (2) is true because \( F \) is an \( \mathcal{R} \)-module.

If \( p_1, p_2 \in \mathcal{N} \) then \([p_1, p_2] = 0 \) and (2) is true because \( \theta \wedge \theta = 0 \).

If \( p_1 \in \mathcal{R}, \ p_2 \in \mathcal{N} \) we have \([p_1, p_2] \in \mathcal{N} \) and

\[
    [p_1, p_2] \cdot f + p_2 \cdot (p_1 \cdot f) = \theta(p_1 \cdot (p_2 \otimes f)) = p_1 \theta(p_2 \otimes f) = p_1 \cdot (p_2 \cdot f)
\]

because \( \theta \) is \( \mathcal{R} \)-equivariant.

\[\square\]

Thm. 3.1 allows one to construct a \( \mathcal{P} \)-module in two steps: the first step is to give the \( \mathcal{R} \)-module \( F \), which encodes the discrete part, the second step is to give \( \theta \), which encodes the continuous part. This will be made precise in §7 about moduli spaces. At present it is convenient to reformulate Thm. 3.1 in terms of vector bundles.

We have seen in the introduction that on a Hermitian symmetric variety the \( \mathcal{P} \)-module \( \mathcal{N} \) corresponds to \( \Omega^1_X \). Since \( [\mathcal{N}, \mathcal{N}] = 0 \), \( \Omega^1_X \) is completely reducible. Let \( E \) be a \( G \)-homogeneous bundle \( E \). The action of \( \mathcal{N} \) over the \( \mathcal{R} \)-module \( \text{gr} E \) induces by Thm. 3.1 an \( \mathcal{R} \)-equivariant morphism of completely reducible representations \( \mathcal{N} \otimes \text{gr} E \rightarrow \text{gr} E \), hence we get a \( G \)-equivariant morphism \( \theta \in \text{Hom}(\text{gr} E, \text{gr} E \otimes T_X)^G \) such that \( \theta \wedge \theta = 0 \). To any \( E \) we can associate the pair \((\text{gr} E, \theta)\). Such pairs are analogous to what is called in \([\text{Simp}]\) a Higgs bundle. The pairs \((\text{gr} E, \theta)\) are the natural extension of Higgs bundles for rational homogeneous varieties, where \( T_X \) is globally generated, so we maintain the terminology of Higgs bundles also in this case.

More precisely, we have

**Definition 3.2** Let \( X \) be a Hermitian symmetric variety. A Higgs bundle on \( X \) is a pair \((F, \theta)\) where \( F \) is an \( \mathcal{R} \)-module and \( \theta: F \rightarrow F \otimes T_X \) is \( G \)-equivariant and satisfies \( \theta \wedge \theta = 0 \).

Higgs bundles form an abelian category, where a morphism between two Higgs bundles \((F_1, \theta_1)\) and \((F_2, \theta_2)\) is a \( G \)-equivariant morphism \( f: F_1 \rightarrow F_2 \) such that \((f \otimes id)\theta_1 = \theta_2 f\). Hence Thm. 3.1 can be reformulated in the following way:
Theorem 3.3 Let $X = G/P$ be a Hermitian symmetric variety. There is an equivalence of categories between

(i) $G$-homogeneous bundles over $X$
(ii) Higgs bundles $(F, \theta)$ over $X$

Remark On any rational homogeneous variety, the category of $G$-homogeneous bundle is equivalent to the category of pairs $(F, \theta)$ where $F$ is an $R$-module and $\theta: F \rightarrow F \otimes T_X$ is $G$-equivariant and satisfies certain relations.

4 The Borel-Weil-Bott theorem

It is well known that the hyperplanes orthogonal to the roots of $G$ divide $\mathcal{H}^\vee$ into regions called Weyl chambers. The fundamental Weyl chamber $D$ of $G$ is

$$D = \{ \sum x_i \lambda_i | x_i \geq 0 \}$$

and it contains exactly the dominant weights. The Weyl group $W$ acts in simple transitive way as a group of isometries on the Weyl chambers. Following [Ko] we denote $g = \sum \lambda_i$. Any homogeneous variety with $\text{Pic} = \mathbb{Z}$ is the quotient $X = G/P(\alpha_j)$ for some $j$, where the Lie algebra of $P(\alpha_j)$ is spanned by the Cartan subalgebra, by the eigenspaces of the negative roots and by the eigenspaces of the positive roots $\alpha = \sum n_i \alpha_i$ such that $n_i \geq 0$ for any $i$ and $n_j = 0$.

The reductive part of $P(\alpha_j)$ has its own fundamental Weyl chamber $D_1 \supset D$ defined by

$$D_1 = \{ \sum x_i \lambda_i | x_i \geq 0 \quad \text{for} \quad i \neq j \}$$

$D_1$ contains exactly the maximal weights of the irreducible representations of $P(\alpha_j)$. Let

$$W^1 = \{ w \in W | wD \subset D_1 \}$$

(see [Ko] Remark 5.13). The cardinality of $W^1$ divides the order of $W$.

Let $H_\phi$ be the hyperplane orthogonal to the root $\phi$ and $r_\phi$ be the reflection with respect to $H_\phi$. It is well known that the reflections $r_\alpha$ generate the Weyl group.

Let $Y_\phi = H_\phi - g$.

Let $\xi_1, \ldots, \xi_m$ be the weights of the representation giving the bundle $\Omega^1_X$, where $m = \dim X$. Let $s_j$ for $j = 1, \ldots, m$ be the reflection through $Y_{\xi_j}$; note that for any weight $\lambda$

$$s_j(\lambda) = r_{\xi_j}(\lambda + g) - g$$

thus $s_j$ and $r_{\xi_j}$ are conjugate elements in $\text{Iso}(\mathcal{H}^\vee)$. It follows that if $w = r_{\xi_1} \cdots r_{\xi_p}$ then $w(\lambda + g) - g = s_1 \cdots s_p(\lambda)$.

An element $\nu \in Z$ is called regular if $(\nu, \phi) \neq 0$ for any root $\phi$, otherwise it is called singular. Observe that $\nu$ is singular iff $\nu \in H_\phi$ for some root $\phi$.

Denote (see [Ko] Remark 6.4)

$$D_1^0 = \{ \xi \in D_1 | g + \xi \text{ is regular} \}$$
$D_1^0$ consists in the subset of $D_1$ obtained removing exactly the $Y_{\xi_i}$. Hence a convenient composition of $s_i$ brings $D$ into the several "chambers" in which $D_1^0$ is divided, which we call Bott chambers (do not confuse them with the usual Weyl chambers). The Bott chambers are obtained by performing a slight "separation" on the Weyl chambers, see the following picture in the case of $P^2 = SL(3)/P(\alpha_1)$ where the three Bott chambers are shadowed.

Now for any $w \in W$ the length $l(w)$ is defined as the minimum number of reflections $r_\alpha$ (with $\alpha$ root) needed to obtain $w$. Any Bott chamber has its own length. Two Bott chambers are said to be adjacent if they have a common hyperplane in their boundary. The lengths of two Bott chambers are consecutive integers.

We state the Bott Theorem (compare with [Ko] theorem 5.14):

Theorem 4.1 (Bott) If $\lambda \in D_1$, then $\exists! w \in W$ s.t. $w^{-1} \in W^1$ and $w(\lambda + g) \in D$.

(i) If $w(\lambda + g)$ belongs to the interior of $D$ then setting $\nu = w(\lambda + g) - g$ we have $H^l(w)(E_\lambda) = V_\nu$ and $H^j(E_\lambda) = 0$ for $j \neq l(w)$.

In particular if $\lambda \in D$ (thus $w$ is the identity) then $H^0(E_\lambda) = V_\lambda$ and $H^i(E_\lambda) = 0$ for $i > 0$.

(ii) If $w(\lambda + g)$ belongs to the boundary of $D$ then $H^j(E_\lambda) = 0 \forall j$.

We recall the result of Kostant ([Ko] Corollary 8.2):

$$\#\{w \in W^1 | l(w) = i\} = \dim H^{2i}(X, C)$$

in particular

$$\#W^1 = \chi(X, C) \quad (4)$$
We explain now the relation of the previous result with the Bott theorem. By Hodge-Deligne theory $H^2i(X, \mathcal{C})$ is isomorphic to $H^2i(X, \Omega^1_X) = H^2i(X, \Omega^1)^G$. Moreover for any irreducible Hermitian symmetric varieties the bundle $\Omega^1$ is irreducible and $\Omega^i$ splits as a sum of direct summands and the number of these summands is equal to $\dim H^{2i}(X, \mathcal{C})$. Moreover on $X = X_1 \times \ldots \times X_r$ with projections $p_i$ we have $\Omega^1_{X_i} = \oplus p_i^* \Omega^1_{X_i}$. The vertices $\lambda$ of the Bott chambers correspond exactly to the direct summands of $\Omega^i$ for some $i$. Indeed for any such a vertex $\lambda$ there exists $w$ as in the Bott theorem (thus $w^{-1} \in W^1$) such that $w(\lambda + g) - g = 0$ (i.e. $\lambda = w^{-1}(g) - g$) and $l(w) = i$.

We note the following consequences of the results of Bott and Kostant

**Theorem 4.3** Let $X = G/P$ be a Hermitian symmetric variety.

(i) There is a natural isomorphism $\text{Hom}(E_\lambda \otimes \Omega^1_X, E_\nu) \rightarrow \text{Ext}^i(E_\lambda, E_\nu)^G \forall \lambda, \nu \in D_1$. Both spaces are isomorphic to $\mathbb{C}$ or to 0 for $i = 1$.

(ii) If $X$ is irreducible and $\text{Ext}^i(E_\lambda, E_\nu)^G \neq 0$ then $\mu(E_\nu) = \mu(E_\lambda) + i \mu(\Omega^1)$.

(iii) If $X = X_1 \times \ldots \times X_r$, product of irreducible ones, and $\text{Ext}^i(E_\lambda, E_\nu)^G \neq 0$ define $a_i = \frac{1}{\mu(\Omega^1_{X_i})}$. Then with this choice for any $i$ we have $\mu_a(\Omega^1_X) = \mu_a(p_i^* \Omega^1_{X_i}) = 1$ (see §2) and we get $\mu_a(E_\nu) = \mu_a(E_\lambda) + i$.

**Proof:** (i) By Cor. 4.2 only the last statement needs an explanation. In fact all the irreducible components of $E_\lambda \otimes \Omega^1_X$ have multiplicity one. Indeed look at (ii) and observe that eigenspaces of the roots of $G$ have dimension 1.

(ii) All direct summands of $E_\lambda \otimes \Omega^1_X$ have the same $\mu$ equal to $\mu(E_\lambda \otimes \Omega^1_X) = \mu(E_\lambda) + i \mu(\Omega^1_X)$.

(iii) follows immediately as in (ii). 

**Remark** For $i \geq 2$ there are some irreducible components of $E_\lambda \otimes \Omega^1_X$ which appear with multiplicity $\geq 2$. For example in the Grassmannian $Gr(\mathbb{P}^4, \mathbb{P}^5) = SL(4)/P(\alpha_2)$, let $T$ be the tangent bundle. We have that $\text{Ext}^2(T, T(-2))^G$ contains $H^2(\Omega^2) = \mathbb{C}^2$, and correspondingly $T \otimes \Omega^2$ contains two copies of $T(-2)$. Indeed $\Omega^2$ splits into two irreducible summands and there is a copy of $T(-2)$ for each of these summands. In the case of quadrics $Q_n$ with $n \geq 5$, the list of weights of the irreducible $\Omega^2$ contains a weight of multiplicity $[\frac{n-1}{2}]$, in this case for $\lambda \gg 0$ the tensor product $E_\lambda \otimes \Omega^2$ contains a direct summand with multiplicity $[\frac{n-1}{2}]$. In the case $X = \mathbb{P}^n$ all irreducible summands of $E_\lambda \otimes \Omega^2$ appear with multiplicity one by the formula (P-II (6.9)), indeed in this case all the weights of $\Omega^2$ are distinct.
Corollary 4.4 If $E$ is an irreducible bundle on a Hermitian symmetric variety then $\text{Ext}^i(E, E)^G = 0$ for $i > 0$.

Proof Apply Thm. 4.3 for $\lambda = \nu$. \qed

Corollary 4.5 For every $i < \dim X$ and $\lambda \in D_1$ there are $\lambda'$ and $s_j$ such that $\lambda' = s_j(\lambda)$ and $H^i(E_\lambda) = H^{i+1}(E_{\lambda'})$ or $H^i(E_\lambda) = H^{i-1}(E_{\lambda'})$. In particular $\lambda$ and $\lambda'$ differ by a multiple of $\xi_j$. There is exactly one of such $\lambda'$ in every Bott chamber having a common boundary with the chamber containing $E_\lambda$.

Proof Consider the vertex $\lambda_0$ of the Bott chamber containing $\lambda$. Then consider all the $s_j$ such that $s_j(\lambda_0)$ is the maximal weight of a summand of $\Omega^{i+1}$. Such $s_j$’s work. \qed

Remark $\lambda'$ and $s_j$ of the previous corollary are unique in the case of $\mathbb{P}^n$, but they are not unique for general Grassmannians.

In the following tables we list all the vertices of the Bott chambers in the cases $\mathbb{P}^4$ and $Gr(1, 4)$. The 4-ple $(x_1, x_2, x_3, x_4)$ denotes the weight $\sum x_i \lambda_i$. An arrow labelled with the root $\beta$ means the reflection

$$\cdot \mapsto r_{\beta}(\cdot + g) - g$$

So the arrow labelled with $-\xi_j$ means the reflection $s_j$. For example $(-2, 1, 0, 0) = r_{\alpha_1} ((0, 0, 0, 0) + g) - g = s_1(0, 0, 0, 0)$. To check the tables it can be useful Lemma 4.7.

$\mathbb{P}^4$

- $(0, 0, 0, 0)
- (-2, 1, 0, 0)
- (-3, 0, 1, 0)
- (-4, 0, 0, 1)
- (-5, 0, 0, 0)$

$Gr(1, 4)$

- $(0, 0, 0, 0, 0, 0)$
- $(1, 0, 0, 0, 0, 0)$
- $(2, 1, 0, 0, 0, 0)$
- $(3, 2, 0, 0, 0, 0)$
- $(4, 3, 0, 0, 0, 0)$
- $(5, 4, 0, 0, 0, 0)$
Proposition 4.6 (Bott on $\mathbb{P}^n$) Let $X = \mathbb{P}^n = SL(n+1)/P(\alpha_1)$

(i) if $\lambda$ is any weight and $\exists i \in \mathbb{N}$ s.t. $\nu := r_{\alpha_1} \ldots r_{\alpha_i}(\lambda + g) - g \in D$ then $H^j(E_{\lambda}) = V_{\nu}$ and $H^j(E_{\lambda}) = 0$ for $j \neq i$.

In particular, if $\lambda \in D$ then $H^0(E_{\lambda}) = V_{\lambda}$ and $H^i(E_{\lambda}) = 0$ for $i > 0$.

(ii) in the remaining cases $H^i(E_{\lambda}) = 0 \ \forall j$

Proof It is sufficient, by Thm. 4.1, to prove that $W^1 = \{ r_{\alpha_1} \ldots r_{\alpha_i} | i \in \{1 \ldots n\} \} \cup \{1\}$. It is well known that $r_{\alpha_i}(\lambda_j)$ is equal to $\lambda_j$ if $j \neq i$, and to $\lambda_j - \lambda_j + \lambda_j$ if $j = i$ (with the convention that $\lambda_0 = \lambda_{n+1} = 0$). It holds that

$$r_{\alpha_1} \ldots r_{\alpha_i} \left( \sum_{j=1}^{n} p_j \lambda_j \right) = \left( - \sum_{j=1}^{i} p_j \right) \lambda_1 + \sum_{j=1}^{i} p_j \lambda_j + \sum_{j=i+1}^{n} p_j \lambda_j$$

(to check it prove that $r_{\alpha_1} \ldots r_{\alpha_i}(\lambda_j)$ is equal to $\lambda_j$ if $j > i$ and it is equal to $r_{\alpha_1} \ldots r_{\alpha_i}(\lambda_j) = -\lambda_1 + \lambda_i$ if $j \leq i$).

Hence the elements $r_{\alpha_1} \ldots r_{\alpha_i}$ belong to $W^1$ for $i = 1$ to $n$, so these elements, together with the identity, fill $W^1$ by \[4.1\]. The last remark is that $(r_{\alpha_1} \ldots r_{\alpha_i})^{-1} = r_{\alpha_i} \ldots r_{\alpha_1}$.

The point (iv) of the following lemma gives an alternative way to express point (i) of the Bott theorem.
Lemma 4.7  On \( P^n \) we have for \( i = 1 \ldots n \)

\[
(i) \quad 
\xi_i = -\alpha_1 + \ldots - \alpha_i \\
(ii) \quad 
\alpha_1 + \ldots + \alpha_{i+1} = (r_{\alpha_1} \ldots r_{\alpha_i}) (\alpha_{i+1}) \\
(iii) \quad r_{\xi_{i+1}} = (r_{\alpha_i} \ldots r_{\alpha_i})^{-1} r_{\alpha_{i+1}} (r_{\alpha_i} \ldots r_{\alpha_i}) \\
(iv) \quad r_{\xi_1} \ldots r_{\xi_i} = r_{\alpha_1} \ldots r_{\alpha_i}
\]

Proof Straightforward (for (iii) observe that by (ii) \( r_{\alpha_1} + \ldots + \alpha_{i+1} = r_{\alpha_1} \ldots r_{\alpha_i} (\alpha_{i+1}) \)). \( \square \)

Corollary 4.8  On \( P^n \) if \( \lambda = s_{i+1}(\lambda') \) then \( H^i(E_{\lambda}) = H^{i+1}(E_{\lambda'}) \). The converse holds if \( H^i(E_{\lambda}) \neq 0 \).

In particular \( \lambda \) and \( \lambda' \) differ by a multiple of \( \alpha_1 + \ldots + \alpha_{i+1} \). Precisely if \( \lambda = \sum_1^n p_j \lambda_j \) then \( \lambda' = -\sum_1^{i+1} (p_j + 1) (\alpha_1 + \ldots + \alpha_{i+1}) \).

Proof By Prop. 4.6 only the converse needs to be proved. If \( H^{i+1}(E_{\lambda'}) = H^i(E_{\lambda}) \neq 0 \) then by the Bott theorem \( h(\lambda + g) = r_{\alpha_1} h(\lambda' + g) \) where \( h = r_{\alpha_1} \ldots r_{\alpha_i} \) and this implies that \( h(\lambda + g) - h(\lambda' + g) \) is parallel to \( \alpha_{i+1} \), that is \( \lambda - \lambda' \) is parallel to \( h^{-1} \alpha_{i+1} = \alpha_1 + \ldots + \alpha_{i+1} \) (by Lemma 4.7 (ii)). Moreover the last formula holds because \( (\lambda + g, \xi_{i+1}) = -\sum_1^{i+1} (p_j + 1) \).

\( \square \)

5  The Quiver and its Relations

For a quick introduction to theory of quivers and their representations we refer to [King]. More details about quivers with relations can be found in [G-R] or in [H-1].

Definition 5.1  A quiver is an oriented graph \( Q \) with the set \( Q_0 \) of points and the set \( Q_1 \) of arrows. There are two maps \( h, t : Q_1 \to Q_0 \) which indicate respectively the head (sink) and the tail (source) of each arrow.

A path in \( Q \) is a formal composition of arrows \( \beta_m \ldots \beta_1 \) where the tail of an arrow is the head of the previous one. Paths can be summed and composed in natural way, defining the path algebra \( CQ \). It is graded by pairs in \( Q_0 \).

A relation in \( Q \) is a linear form \( \lambda_1 c_1 + \ldots + \lambda_m c_m \) where \( c_i \) are paths in \( Q \) with a common tail and a common head and \( \lambda_i \in C \).

A representation of a quiver \( Q = (Q_0, Q_1) \) is the couple of a set of vector spaces \( \{X_i\}_{i \in Q_0} \) and of a set of linear maps \( \{\varphi_\beta\}_{\beta \in Q_1} \) where \( \varphi_\beta : X_i \to X_j \) if \( \beta \) is an arrow from \( i \) to \( j \).

Let \( \mathcal{R} \) be a homogeneous ideal in the path algebra. A representation of a quiver \( Q \) with relations \( \mathcal{R} \) is a representation of the quiver s.t.

\[
\sum_j \lambda_j \varphi_{1j} \ldots \varphi_{mj} = 0
\]

for every \( \sum_j \lambda_j \beta_{1j} \ldots \beta_{mj} \in \mathcal{R} \).

Let \( (X_i, \varphi_\beta)_{i \in Q_0, \beta \in Q_1} \) and \( (Y_i, \psi_\beta)_{i \in Q_0, \beta \in Q_1} \) be two representations of the quiver \( Q = (Q_0, Q_1) \). A morphism \( f \) from \( (X_i, \varphi_\beta)_{i \in Q_0, \beta \in Q_1} \) to \( (Y_i, \psi_\beta)_{i \in Q_0, \beta \in Q_1} \) is a set
of linear maps $f_i : X_i \to Y_i$, $i \in Q_0$ s.t. for every $\beta \in Q_1$, $\beta$ arrow from $i$ to $j$, the following diagram is commutative:

$$
\begin{array}{ccc}
X_i & \xrightarrow{f_i} & Y_i \\
\varphi_\beta \downarrow & & \downarrow \psi_\beta \\
X_j & \xrightarrow{f_j} & Y_j
\end{array}
$$

It is well known (and easy to be proved) that the category of representations of $Q$ with relations $R$ is equivalent to the category of $CQ/R$-modules.

A quiver $Q$ is called levelled if there exists a function $s : Q_0 \to Q$ such that for any arrow $i \to j$ we have $s(i) = s(j) + 1$.

Let $X = G/P$ be a Hermitian symmetric variety. In order to describe all $G$-homogeneous bundles on $X$ we define a quiver $Q_X$.

**Definition 5.2** Let $Q_X$ be the following quiver. The points of $Q_X$ are the irreducible representations of $R$, which we identify with irreducible $G$-homogeneous bundles over $X = G/P$, or with the corresponding elements in $H^\vee$. Let $E_\lambda$ and $E_\mu$ be irreducible representations with maximal weights $\lambda, \mu \in D_1$. There is an arrow in $Q_X$ from $E_\lambda$ to $E_\mu$ iff $\text{Ext}^1(E_\lambda, E_\mu)^G \neq 0$. The ideal of relations in $Q_X$ will be defined in Def. 5.7.

Observe that if $\text{Ext}^1(E_\lambda, E_\mu)^G \neq 0$ then this group is isomorphic to $C$, by Thm. 4.3.

**Corollary 5.3** If there is an arrow from $E_\lambda$ to $E_\mu$ then $\mu(E_\mu) = \mu(E_\lambda) + \mu(\Omega^1)$. In particular the quiver is levelled (see Def. 5.1) by $\mu_a$ of Thm. 4.3 (iii) (see [Hi1], [Hi2]).

**Proof** By Thm. 4.3.

**Corollary 5.4** The arrows (modulo translation) between elements of the quiver can be identified with the weights of $\Omega^1$ (which are negative roots).

**Proof** From (1) it follows $E_\lambda \otimes \Omega^1 \subset \oplus E_{\lambda + \xi_i}$, then we conclude by Thm. 4.3.

We postpone the description of the relations in the quiver after we have defined the representation associated to a bundle.

**Definition 5.5** We associate to a $G$-homogeneous bundle $E$ the following representation of $Q_X$. Let $grE = \oplus E_\lambda \otimes V_\lambda$, where $V_\lambda = C^k$ and $k$ is the number of times $E_\lambda$ occurs.

To the point $\lambda$ we associate the vector space $V_\lambda$.

For any $\lambda \in Q_0$ let us fix a maximal vector $v_\lambda \in E_\lambda$. For any $\xi_i$ root of $N$ let us fix an eigenvector $n_i \in N$. We have

$$
\text{Ext}^1(grE_\lambda, grE_\mu) = \oplus E_{\lambda, \mu} \text{Hom}(V_\lambda, V_\mu) \otimes \text{Ext}^1(E_\lambda, E_\mu)
$$

We know that $\text{Ext}^1(E_\lambda, E_\mu)^G = \text{Hom}(E_\lambda \otimes \Omega^1, E_\mu)^G$ is equal to $C$ or to $0$, and when it is equal to $C$ then $\mu - \lambda = \xi_j$ for some $j$. We fix the generator $m_{\mu \lambda}$ of $\text{Hom}(E_\lambda \otimes \text{Ext}^1(E_\lambda, E_\mu)^G$.
$\Omega^1, E_\mu)^G$ that takes $v_\lambda \otimes v_j$ to $v_\mu$, indeed $E_\lambda \otimes \Omega^1$ contains a unique summand of multiplicity one isomorphic to $E_\mu$. This normalization appears already in \[B-K\] p. 48. Hence in order to define an element of $\text{Hom}(V_\lambda, V_\mu) \forall \lambda, \mu$ it is enough to give an element of $[E] \in \text{Ext}^1(\text{gr}E, \text{gr}E)^G$ and this is the element corresponding to $\theta$ of Thm. 3.1 (i) according to the isomorphism of Thm. 4.3.

The correspondence $E \mapsto [E]$ is functorial, indeed a $G$-equivariant map $E \rightarrow F$ induces first a morphism $\text{gr}E \rightarrow \text{gr}F$ and then a morphism of representations of $Q_X$ $[E] \rightarrow [F]$.

A direct consequence of Thm. 3.1 is

**Theorem 5.6** Let $G/P$ be a Hermitian symmetric variety.

(i) For any $G$-homogeneous bundle $E$ we have $m([E]) = 0$, where $m$ is the invariant Yoneda morphism recalled in §2

$$m: \text{Ext}^1(\text{gr}E, \text{gr}E)^G \rightarrow \text{Ext}^2(\text{gr}E, \text{gr}E)^G$$

(ii) Conversely for any $R$-module $F$ and any $e \in \text{Ext}^1(F, F)^G$ such that $m(e) = 0$ there exists a $G$-homogeneous bundle $E$ such that $\text{gr}E = F$ and $e = [E]$. 

**Remark** It is well known, although we do not need it, that for any bundle $F$ the usual Yoneda morphism $\text{Ext}^1(F, F) \rightarrow \text{Ext}^2(F, F)$ is the quadratic part of the Kuranishi morphism. In particular the invariant Yoneda morphism $\text{Ext}^1(F, F)^G \rightarrow \text{Ext}^2(F, F)^G$ is the invariant piece of the quadratic part of the Kuranishi morphism.

**Remark** We recall that the functor $E \mapsto \text{gr}E$ from $P - \text{mod}$ to $R - \text{mod}$ is exact. Our description of the quiver and Thm. 5.6 can be thought roughly as an additional structure on $R$-mod that allows one to invert the functor $\text{gr}$.

The theorem shows how to define relations in $Q_X$ in order to get an equivalence of categories. The relations have to reflect the vanishing $m(e) = 0$. We have to remark that since in Def. 5.5 we have fixed a normalization, the relations in $Q_X$ can be changed up to scalar multiplications of the maps involved (see Cor. 8.5).

**Definition 5.7** Write $e \in \text{Ext}^1(\text{gr}E, \text{gr}E)^G$ as

$$e = \sum g_{\mu\lambda}m_{\mu\lambda}$$

where $m_{\mu\lambda} \in \text{Ext}^1(E_\lambda, E_\mu)^G$ were fixed in Def. 5.3 and $g_{\mu\lambda} \in \text{Hom}(V_\lambda, V_\mu)$ come from the isomorphism (5). The equation $m(e) = 0$ becomes

$$\sum_{\nu, \lambda} \left( \sum_{\mu} (g_{\nu\mu}g_{\mu\lambda})(m_{\nu\mu} \wedge m_{\mu\lambda}) \right) = 0$$

where $m_{\nu\mu} \wedge m_{\mu\lambda} \in \text{Ext}^2(E_\lambda, E_\mu)^G$ is the Yoneda product of $m_{\nu\mu}$, $m_{\mu\lambda}$ and $g_{\nu\mu}g_{\mu\lambda} \in \text{Hom}(V_\lambda, V_\nu)$ are the composition maps. For any fixed $\lambda$ and $\nu$, the equation

$$\sum_{\mu} (g_{\nu\mu}g_{\mu\lambda})(m_{\nu\mu} \wedge m_{\mu\lambda}) = 0$$

(6)
gives a system of at most \( \dim \text{Ext}^2(E_\lambda, E_\mu)^G \) quadratic equations in the unknowns \( g_{\nu\mu} \) and \( g_{\mu\lambda} \).

We define the relations in \( Q_X \) as the ideal generated by all these quadratic equations for any pair \( \lambda \) and \( \nu \).

**Theorem 5.8** (i) For any homogeneous bundle \( E \) on \( X \) Hermitian symmetric variety, \([E]\) satisfies these relations, hence it is a representation of the quiver \( Q_X \) with relations.

(ii) Conversely given a representation \( e \) of the quiver \( Q_X \) with relations, there exists a homogeneous bundle \( E \) such that \( e = [E] \).

**Proof** By definition the relations are equivalent to \( \theta \wedge \theta = 0 \). Hence the statement is equivalent to Thm. 3.1 and to Thm. 5.6 (see also next Example 5.13). \( \square \)

The isomorphism class of \([E]\) lives in \( \text{Ext}^1(\text{gr}E, \text{gr}E)^G / \text{Aut}^G(\text{gr}E) \). We remark that in each case the isomorphism class of the bundle determines the isomorphism class of the representation of \( Q_X \) (by the functoriality). Hence Thm. 5.6 can be reformulated in the following way:

**Theorem 5.9** (Reformulation of Thm. 5.8) Let \( X = G/P \) be a Hermitian symmetric variety. There is an equivalence of categories among

(i) \( G \)-homogeneous bundles over \( X \).

(ii) finite dimensional representations of the quiver (with relations) \( Q_X \) (associating zero to all but a finite number of points of \( Q_X \)).

(iii) Higgs bundles \((F, \theta)\) over \( X \).

**Subquivers and quotient quivers** Since there is no danger of confusion, we denote by \( CQ_X \) the path algebra of the quiver with relations \( Q_X \), meaning that the algebra has been quotiented by the ideal of relations. There are two basic constructions for quiver representations that we will need.

**Definition 5.10** Let \( \text{gr}E = \oplus V_\lambda \otimes E_\lambda \) so that \( V = \oplus V_\lambda \) is a \( CQ_X \)-module. For any subspace \( V' \subset V \) the submodule generated by \( V' \) defines a homogeneous subbundle of \( E \). In case \( V' = V_{\lambda'} \) for some \( \lambda' \) we will call this subbundle the bundle defined by all arrows starting from \( \lambda' \).

Also \( (V' : CQ_X) := \{v \in V | fv \in V' \ \forall f \in CQ_X\} \) is a submodule and the quotient \( V/(V' : CQ_X) \) defines a homogeneous quotient of \( E \). Let \( \pi_{\lambda'} : V \to V_{\lambda'} \) be the projection; in case \( V' = \ker \pi_{\lambda'} \) we have \( V/(V' : CQ_X) = V/\{v \in V | \pi_{\lambda'}fv = 0 \ \forall f \in CQ_X\} \) and we will call this quotient bundle the bundle defined by all arrows arriving in \( \lambda' \).

**Example 5.11** (compare with [Hi2]) Let \( P^3 = P(V) \). The bundle \( E = \lambda^2 V \) on \( X = \text{Gr}(P^1, P^3) \) has \( \text{gr}E = O(-1) \oplus \Omega^1(1) \oplus O(1) \). The corresponding representation of the quiver associates to

\[
\begin{array}{c}
\mathcal{O}(1) \\
\mathcal{O}(-1) & \leftarrow & \Omega^1(1)
\end{array}
\]
the diagram of linear maps

\[ \begin{align*}
\mathbb{C} & \xrightarrow{\theta_1} \mathbb{C} \\
\mathbb{C} & \xrightarrow{\theta_2} \mathbb{C}
\end{align*} \]

Equivalently \( \theta \) splits into the two summands

\[ \theta_1: \mathcal{O}(1) \otimes \Omega^1 \to \Omega^1(1) \]

and

\[ \theta_2: \Omega^1(1) \otimes \Omega^1 \to \mathcal{O}(-1) \]

and satisfies \( \theta \wedge \theta = 0 \) because

\[ \text{Ext}^2(\mathcal{O}(1), \mathcal{O}(-1))^G = \text{Hom}(\mathcal{O}(1) \otimes \Omega^2, \mathcal{O}(-1))^G = 0 \]

In fact in \( \mathcal{Q}_X \) the commutativity of the diagram

\[ \begin{align*}
0 & \quad \leftarrow \quad \mathcal{O}(1) \\
\mathcal{O}(-1) & \quad \leftarrow \quad \Omega^1(1)
\end{align*} \]

is not a relation.

**Theorem 5.12** Let \( X \) be an irreducible Hermitian symmetric variety. The number of connected components of \( \mathcal{Q}_X \) is given by the following table

| Grassmannians | Odd Quadrics | Even Quadrics | Spinor Varieties |
|---------------|--------------|---------------|------------------|
| \( SL(n+1)/P(\alpha_{n+1}) \) | \( \text{Spin}(2n+1)/P(\alpha_1) \) | \( \text{Spin}(2n+2)/P(\alpha_1) \) | \( \text{Spin}(2n+1)/P(\alpha_{n+1}) \) |
| \( Gr(P^n, P^n) \) | \( Q_{2n-1} \) \( n \geq 2 \) | \( Q_{2n} \) \( n \geq 2 \) | \( \frac{1}{2} Gr(P^n, Q_{2n}) \) \( n \geq 3 \) |
| \( n+1 \) | \( 2 \) | \( 4 \) | \( 4 \) |

| Lagrangian Grassmannians | Cayley Plane | \( X_{27} \) |
|-------------------------|-------------|--------------|
| \( Gr_n(P^{n-1}, P^{2n-1}) \) | \( E_6/P(\alpha_1) \) | \( E_7/P(\alpha_1) \) |
| \( n \geq 2 \) | \( 3 \) | \( 2 \) |

**Proof** The number of connected components is equal to the index of the lattice \( \langle \xi_1, \ldots, \xi_m \rangle_{\mathbb{Z}} \) in \( \langle \lambda_1, \ldots, \lambda_n \rangle_{\mathbb{Z}} \). It is easy to check in any case that

\[ \langle \xi_1, \ldots, \xi_m \rangle_{\mathbb{Z}} = \langle \alpha_1, \ldots, \alpha_n \rangle_{\mathbb{Z}} \]

by the shape of the roots (the list in the exceptional cases is in [Snow]). Hence the number of connected components is given in any case by the determinant of the corresponding Cartan matrix, and these are well known (see e.g. [F-H] exerc. 21.18).

Every homogeneous bundle \( E \) on \( X \) splits as \( E = \bigoplus E^{(i)} \) where the sum is over the connected components of \( \mathcal{Q}_X \), and \( gr(E^{(i)}) \) contains only irreducible bundles corresponding to points of the connected component labelled by \( i \). We analyze separately
each of the irreducible Hermitian symmetric varieties. The decomposition of \( E_\lambda \otimes \Omega^1 \) in the cases where \( G \) is of type \( A, D \) or \( E \) appears already in Prop. 2 of [B-K].

- When \( G = SL(\nu + 1) \) then \( X = G/P(\alpha_{\nu+1}) \) is the Grassmannian \( Gr(P^{k}, P^{n}) \). In this case all the roots \( \Omega_{X}^{1} \) are \( \beta_{ij} = -\sum_{i=1}^{\nu} \alpha_{i} \) for \( 1 \leq i \leq k + 1 \leq j \leq \nu \). If \( U \) and \( Q \) are the universal and the quotient bundle, it is well known that \( \Omega^{1} = U \otimes Q^{*}, \Omega^{2} = [\text{Sym}^{2}U \otimes \wedge^{2}Q^{*}] \oplus [\wedge^{2}U \otimes \text{Sym}^{2}Q^{*}] \).

Here \( \mu(\Omega^{1}) = -\frac{n+1}{(k+1)(n-k)} \). Every irreducible bundle on \( X \) can be described by \( E = S^{\alpha}U \otimes S^{\beta}Q^{*}(t) \) for some partitions \( \alpha, \beta \) and for some \( t \in \mathbb{Z} \). The \( \nu + 1 \) connected components are distinguished by the class of \( (|\alpha|, |\beta|) \in \mathbb{Z}_{2} \times \mathbb{Z}_{2} \) modulo the lattice \( \langle (-1, 1), (k + 1, n - k) \rangle \mathbb{Z} \). If \( G.C.D. (n + 1, (k + 1)(n - k)) = 1 \) the components are distinguished more easily by \( (k + 1)(n - k) \mu(E) = 0, 1, \ldots, n(\mod \ n + 1) \).

- When \( k = 0 \) we get \( X = P^{n} \). Due to the importance of this case in the applications we stress our attention on it. We saw before in Lemma 15 the corresponding roots \( \xi_{1}, \ldots, \xi_{n} \). We have the simple formulas (of course some summands can be zero)

\[
E_{\lambda} \otimes \Omega^{1} = \oplus_{i=1}^{n} E_{\lambda + \xi_{i}} \\
E_{\lambda} \otimes \Omega^{2} = \oplus_{1 \leq i < j \leq n} E_{\lambda + \xi_{i} + \xi_{j}}
\]

In Cor. 3.3 we will see that the relations in the quiver \( Q_{P^{n}} \) can be summed up by saying that for any weight \( \lambda \in D_{1} \) and any \( 1 \leq i < j \leq n \) all diagrams

\[
\begin{array}{cc}
E_{\lambda + \xi_{i}} & \leftarrow \ E_{\lambda} \\
\downarrow & \downarrow \\
E_{\lambda + \xi_{i} + \xi_{j}} & \leftrightarrow E_{\lambda + \xi_{j}}
\end{array}
\]

have to be commutative. This fits with [B-K]. The quiver \( Q_{P^{n}} \) is isomorphic to the half-space of \( \mathbb{Z}^{n} \) defined by the inequalities \( x_{1} \geq x_{2} \geq \ldots \geq x_{n} \) for \( (x_{1}, \ldots, x_{n}) \in \mathbb{Z}^{n} \) with arrows following the standard basis (with the directions reversed). Here \( \mu(\Omega^{1}) = -\frac{n+1}{n} \).

The \( n + 1 \) connected components are distinguished by \( n \mu(E) = 0, 1, \ldots, n(\mod \ n + 1) \) for an irreducible \( E \).

- In the case of odd dimensional quadrics \( Spin(2n + 1)/P(\alpha_{1}) = Q_{2n-1} \subset P^{2n} \) we have that \( \Omega^{1} \) has maximal weight \( -\alpha_{1} = 2\lambda_{2} - 2\lambda_{1} \) for \( 2 < 2 \) and has maximal weight \( -\alpha_{1} = \lambda_{2} - 2\lambda_{1} \) for \( n \geq 3 \), while \( \Omega^{2} \) has maximal weight \( 2\lambda_{2} - 3\lambda_{1} \) for \( n = 3, 2\lambda_{3} - 3\lambda_{1} \) for \( n \geq 4 \). Denote again by \( \xi_{1}, \ldots, \xi_{m} \) \( (m = 2n - 1) \) the roots of \( \Omega^{1} \). We have

\[
E_{\lambda} \otimes \Omega^{1} = \oplus_{i=1}^{m} E_{\lambda + \xi_{i}}
\]

while \( E_{\lambda} \otimes \Omega^{2} \) is contained in \( \oplus_{1 \leq i < j \leq m} E_{\lambda + \xi_{i} + \xi_{j}} \) and can be determined according to \( \lambda \) by the explicit algorithm in [L]. When \( \lambda \gg 0 \) then we have the equality. Here \( \mu(\Omega^{1}) = -1 \) and \( \mu(S) = -\frac{1}{2} \) for the spinor bundle. The two connected components are distinguished by \( 2\mu(E) = 0, 1(\mod \ 2) \) for an irreducible \( E \).

- In the case of even dimensional quadrics \( Spin(2n + 2)/P(\alpha_{1}) = Q_{2n} \subset P^{2n+1} \) \( (\lambda_{n} \) and \( \lambda_{n+1} \) correspond to the two spinor bundles) we have that \( \Omega^{1} \) has maximal weight \( \lambda_{2} + \lambda_{3} - 2\lambda_{1} \) for \( n = 2 \) and \( \lambda_{2} - 2\lambda_{1} \) for \( n \geq 3 \), while \( \Omega^{2} \) splits with two maximal weights \( 2\lambda_{2} - 3\lambda_{1} \) and \( 2\lambda_{3} - 3\lambda_{1} \) for \( n = 2 \) (this is the grassmannian of lines in \( P^{3} \) already considered), and it has maximal weight \( \lambda_{3} + \lambda_{4} - 3\lambda_{1} \) for \( n = 3 \) and \( \lambda_{3} - 3\lambda_{1} \) for
\( n \geq 4 \). Here \( \mu(\Omega^1) = -1 \) and \( \mu(S) = -\frac{1}{2} \) for the two spinor bundles. The knowledge of \( \mu \) is not enough to distinguish the several components. If \( E = E_{\sum p_i \lambda_i} \) the four components are distinguished by \([ (p_n, p_{n+1}) ] \in \mathbb{Z}_2 \times \mathbb{Z}_2 \).

- In the case of spinor variety \( \text{Spin}(2n+2)/P(\alpha_{n+1}) \) we have the universal bundle \( U \) of rank \( n+1 \) and it is well known that \( \Omega^1 = \wedge^2 U \) and \( \Omega^2 = \wedge^2(\wedge^2 U) = S^{2,1,1} U \). Let \( m = \binom{n+1}{2} \) and let \( \xi_1, \ldots, \xi_m \) be the roots of \( \Omega^1 \). Then it is easy to check that

\[
E_\lambda \otimes \Omega^1 = \oplus_{i=1}^{m} E_{\lambda + \xi_i}
\]

while \( E_\lambda \otimes \Omega^2 \) is contained in \( \oplus_{1 \leq i < j \leq m} E_{\lambda + \xi_i + \xi_j} \) that can be determined according to \( \lambda \) by the classical Littlewood-Richardson rule (because the semisimple part of \( P(\alpha_{n+1}) \) is \( SL(n+1) \)). When \( \lambda \gg 0 \) then we have the equality. Here \( \mu(\Omega^1) = -\frac{4}{n+1} \). If \( \text{G.C.D.}(4,n+1)=1 \) then the four connected components are distinguished by \((n+1) \mu(E) = 0, 1, 2, 3 (\text{mod} \ 4) \). Otherwise the knowledge of \( \mu \) is not enough to distinguish the several components. Every irreducible bundle on \( X \) can be described by \( E = S^{\alpha} U \otimes \mathcal{O}(t) \) for some partition \( \alpha \) and some integer \( t \). The four connected components are distinguished by the class of \((|\alpha|, t) \in \mathbb{Z}_2 \times \mathbb{Z}_2 \).

- In the case of lagrangian maximal grassmannians \( Sp(2n)/P(\alpha_n) \) we have the universal bundle \( U \) of rank \( n \) and it is well known that \( \Omega^1 = \text{Sym}^2 U \) and \( \Omega^2 = \wedge^2(\text{Sym}^2 U) = S^3 U \). Let \( m = \binom{n+1}{2} \) and let \( \xi_1, \ldots, \xi_m \) be the roots of \( \Omega^1 \). In this case \( E_\lambda \otimes \Omega^1 \) is contained in \( \oplus_{i=1}^{m} E_{\lambda + \xi_i} \) and the inclusion can be strict. Indeed also this computation can be done by using the classical Littlewood-Richardson rule. Note that we can write the \( \xi_i \) as \( \gamma_j + \gamma_k \) where \( \gamma_j \) are the weights of \( U \). A fortiori \( E_\lambda \otimes \Omega^2 \) is contained in \( \oplus_{1 \leq i < j \leq n} E_{\lambda + \xi_i + \xi_j} \) and it can be determined according to \( \lambda \) by the classical Littlewood-Richardson rule. Here \( \mu(\Omega^1) = -\frac{2}{n} \). The two connected components are distinguished by \( n \mu(E) = 0, 1 (\text{mod} \ 2) \) for an irreducible \( E \).

- In the case of the Cayley plane \( E_6/P(\alpha_1) = \mathbb{O} \mathbb{P}^2, (\mathbb{M}, \mathbb{M}) \) the semisimple part of \( P(\alpha_1) \) is \( \text{Spin}(10) \). \( E_{\lambda_2} \) is a twist of one of the two spinor bundles and \( \Omega^1 = E_{\lambda_2}(-2) \).

Hence \( \Omega^2 = E_{\lambda_2}(-3) \) is irreducible. Here \( \mu(\Omega^1) = -\frac{3}{4} \). The three connected components are distinguished by \( 4 \mu(E) = 0, 1, 2 (\text{mod} \ 3) \) for an irreducible \( E \). The Cayley plane has an intrinsic interest because it is a Severi variety.

- Also the 27-dimensional case \( E_7/P(\alpha_1) \) has \( \Omega^1 = E_{\lambda_3}(-2) \) and \( \Omega^2 = E_{\lambda_3}(-3) \) both irreducible. Here \( \mu(\Omega^1) = -\frac{3}{8} \). The two connected components are distinguished by \( 3 \mu(E) = 0, 1 (\text{mod} \ 2) \) for an irreducible \( E \).

The case of the projective plane \( \mathbb{P}^2 \) allows an explicit description of some interest. Let \( (x, y) \in \mathcal{N} \simeq \mathbb{C}^2 \). Consider the linear maps given by matrices with coefficients in \( \wedge^* \mathcal{N} \)

\[
C_k = \frac{1}{k+1} \begin{bmatrix}
  x & y \\
  \vdots & \ddots \\
  x & y
\end{bmatrix}
\]

of size \( k \times (k+1) \)
Now it is easy to check that

\[ C_k \wedge C_{k+1} = 0 \quad B_{k+1} \wedge B_k = 0 \quad C_{k+1} \wedge B_{k+1} + B_k \wedge C_k = 0 \quad (7) \]

The interpretation in terms of representations is the following. The parabolic subgroup \( P(\alpha_1) \subset SL(3) \) has the form

\[
P(\alpha_1) = \left\{ \begin{bmatrix} e & x & y \\ 0 & a_{11} & a_{12} \\ 0 & a_{21} & a_{22} \end{bmatrix} \, | \, e \det A = 1 \right\}
\]

The irreducible representation of \( P(\alpha_1) \) corresponding to \( Sym^p Q(t) \) is defined by \( Sym^p A - eI \). Consider the derivative

\[ P = \text{Lie}P(\alpha_1) \rightarrow \text{gl}(Sym^p \mathbb{C}^2) \]

and call it (with a slight abuse of notation) \( Sym^p A - teI \). The extension \( w \in Ext^1(Sym^k Q, Sym^{k-1} Q(-1))^G = \mathbb{C} \) defines a bundle with representation

\[
\begin{bmatrix}
Sym^{k-1} A + eI & wC_k \\
0 & Sym^k A
\end{bmatrix}
\]

where \( w \) is a scalar multiple, and \( w = 0 \) iff the extension splits.

Analogously, the extension \( w \in Ext^1(Sym^k Q(2), Sym^{k+1} Q)^G = \mathbb{C} \) defines a bundle with representation

\[
\begin{bmatrix}
Sym^{k+1} A & wB_k \\
0 & Sym^k A - 2eI
\end{bmatrix}
\]

where \( w \) is a scalar multiple, which is zero iff the extension splits. By Thm. 3.1 several extensions as in \( \text{(8)} \) and \( \text{(9)} \) fit together to give a representation \( \rho \) of \( P \) if and only if \( \rho|_N \wedge \rho|_N = 0 \) (see the next Example 5.13). We remark that \( \text{(7)} \) are equivalent to the fact that the only relations in \( Q_{p^2} \) are the commutativity ones (see Cor. 8.5) in all the square diagrams and the relation \( a_2b_1 = 0 \) in the diagrams

\[
\begin{array}{ccc}
\mathcal{O}(t) & \rightarrow & b_1 \\
\mathcal{O}(t-3) & \twoheadleftarrow & Q(t-2)
\end{array}
\]

for any \( t \in \mathbb{Z} \). These last relations can be seen as the commutativity in the diagrams

\[
\begin{array}{ccc}
0 & \leftarrow & \mathcal{O}(t) \\
\downarrow & \leftarrow & \mathcal{O}(t) \\
\mathcal{O}(t-3) & \twoheadleftarrow & Q(t-2)
\end{array}
\]
Example 5.13 We describe explicitly the homogeneous bundle on $\mathbb{P}^2 = \mathbb{P}(V)$ corresponding to the representation that associates to

$$
\begin{array}{ccc}
O & \leftarrow & Q(1) \\
\downarrow & & \downarrow \\
Q(-2) & \leftarrow & \text{Sym}^2 Q(-1)
\end{array}
$$

the diagram of linear maps

$$
\begin{array}{ccc}
C^a & \xrightarrow{\gamma_1} & C^b \\
\downarrow{\beta_1} & & \downarrow{\beta_2} \\
C^c & \xrightarrow{\gamma_2} & C^d
\end{array}
$$

where $a$, $b$, $c$, $d$ are positive integers. We get

$$
\rho \begin{bmatrix}
e & x & y \\
0 & a_{11} & a_{12} \\
0 & a_{21} & a_{22}
\end{bmatrix} = \begin{bmatrix}
A^c + 2eI & \gamma_2 \otimes C_2 & \beta_1 \otimes B_1 & 0 \\
0 & (\text{Sym}^2 A)^d + eI & 0 & \beta_2 \otimes B_2 \\
0 & 0 & 0 & \gamma_1 \otimes C_1 \\
0 & 0 & 0 & A^b - eI
\end{bmatrix}
$$

and this is a $P$-module iff (by Thm. 3.1)

$$
\begin{bmatrix}
0 & \gamma_2 \otimes C_2 & \beta_1 \otimes B_1 & 0 \\
0 & 0 & \beta_2 \otimes B_2 \\
0 & 0 & \gamma_1 \otimes C_1 \\
0 & 0 & 0 & 0
\end{bmatrix} \wedge
\begin{bmatrix}
0 & \gamma_2 \otimes C_2 & \beta_1 \otimes B_1 & 0 \\
0 & 0 & \beta_2 \otimes B_2 \\
0 & 0 & \gamma_1 \otimes C_1 \\
0 & 0 & 0 & 0
\end{bmatrix} = 0
$$

which is equivalent by (7) to

$$
\gamma_2 \cdot \beta_2 - \beta_1 \cdot \gamma_1 = 0
$$

confirming the commutativity relations. In the special case $a = b = c = d = 1$ and all the maps given by the identity this bundle is $\text{ad}V$.

The isomorphism classes of representations are equivalent to the orbits in $m^{-1}(0)$ with respect to the $\text{Aut}_G(\text{gr}E)$-action.

6 Computation of Cohomology

In all this section $X$ is a Hermitian symmetric variety of ADE type.

We want to describe now how to compute the cohomology of a homogeneous bundle $E$ on $X$ from the representation of the quiver.

We need the following easy lemma.

Lemma 6.1 [C-E] lemma XV 1.1

Let the following diagram be commutative

$$
\begin{array}{ccc}
C & \xrightarrow{\phi} & A' \\
\downarrow{\psi} & & \downarrow{\eta} \\
A & \xrightarrow{\psi} & A''
\end{array}
$$
and let the row be exact. Then

\[ Im \phi' / Im \phi \simeq Im \psi \]

Let

\[ 0 = E_0 \subset E_1 \subset E_2 \subset \ldots \subset E_r = E \]

be a filtration of a vector bundle (not necessarily homogeneous).

Let now

\[ Z_j^p := Ker \left( H^j(E_{p+1}/E_p) \xrightarrow{\partial} H^{j+1}(E_p) \right) \]

\[ B_j^p := Im \left( H^{j-1}(E/E_{p+1}) \xrightarrow{\partial} H^{j}(E_{p+1}/E_p) \right) \]

where the maps are the boundary maps of the two obvious exact sequences.

The following proposition follows from the discussion at the beginning of chapter XV of [C-E]. For the convenience of the reader we sketch the proof.

**Theorem 6.2** \( B_j^p \subset Z_j^p \) and

\[ H^j(E) \simeq \bigoplus_{p=0}^{r-1} Z_j^p / B_j^p \]

**Proof** We have the commutative diagram

\[
\begin{array}{ccc}
H^j(E_{p+1}) & \xrightarrow{\phi} & H^j(E/E_p) \\
\downarrow{\phi} & & \downarrow{\eta} \\
H^{j-1}(E/E_{p+1}) & \xrightarrow{\phi'} & H^j(E_{p+1}/E_p)
\end{array}
\]

hence \( B_j^p \subset Z_j^p \) and from Lemma 6.1 we get

\[ Im \left( H^j(E_{p+1}) \xrightarrow{\phi'} H^j(E/E_p) \right) \simeq Im \phi / Im \phi' = Im \phi / Ker \eta = Z_j^p / B_j^p \] (10)

Consider also the diagram

\[
\begin{array}{ccc}
H^j(E_{p+1}) & \xrightarrow{\phi} & H^j(E/E_p) \\
\downarrow{\phi} & & \downarrow{\eta} \\
H^j(E) & \xrightarrow{\phi_p} & H^j(E/E_p)
\end{array}
\]

we get again from Lemma 6.1

\[ Im \left( H^j(E_{p+1}) \xrightarrow{\psi} H^j(E/E_p) \right) \simeq Im(\phi_p) / Im(\phi_{p-1}) \] (11)

and since we have the graduation

\[ H^j(E) \simeq \bigoplus_p Im(\phi_p) / Im(\phi_{p-1}) \]

we get the result. \( \Box \)
We return now to the case of homogeneous bundles.

We need a short digression about homogeneous bundles whose quiver representation has support on an $A_n$-type quiver, that is $gr E = \oplus V_\lambda \otimes E_\lambda$ and $V_\lambda$ is zero outside a path connecting the vertices $\{\lambda + p\xi_j | 0 \leq p \leq k\}$.

The following theorem is well known since the former work on quivers by P. Gabriel (see [G-R]).

**Theorem 6.3** Every representation of the $A_m$-quiver is the direct sum of irreducible representations with dimension vector

$$(0,0,\ldots,0,1,1,\ldots,1,0,\ldots,0)$$

where the nontrivial linear maps are isomorphisms.

The reader can enjoy to deduce the previous theorem as a consequence of Thm. 5.9 for $X = \mathbb{P}^1$ and the Segre-Grothendieck theorem, which says that every bundle on $\mathbb{P}^1$ splits as the sum of line bundles.

**Proposition 6.4** Let $E_\lambda$ and $E_\mu$ be in two adjacent Bott chambers with $H^i(E_\lambda) \simeq H^{i+1}(E_\mu) \simeq W$, then $\mu - \lambda = k_\xi_j$ for some integer $k$ and some root $\xi_j$ of $\Omega^1$. We have

$$\dim \text{Hom} \left( E_\lambda \otimes \text{Sym}^k \Omega^1, E_\mu \right)^G = 1$$

**Proof** By (1) it is enough to show that there are no other weights among $\{a_1 \xi_{i_1} + \ldots + a_h \xi_{i_h} | \sum a_i = k\}$ which are equal to $\mu - \lambda$. With the ADE assumption, $\xi_j$ is a vertex of the convex polytope containing the weights of $\Omega^1$, because all the roots have the same length. Hence $k_\xi_j$ is a vertex of the convex polytope containing the weights of $\text{Sym}^k \Omega^1$. \qed

**Proposition 6.5** Let $\xi_j$ be a weight of $\Omega^1$.

$$\text{Ext}^2(E_\lambda, E_{\lambda+2\xi_j})^G = \text{Hom}(E_\lambda \otimes \Omega^2, E_{\lambda+2\xi_j})^G = 0$$

**Proof** Since $\xi_j$ is a vertex of the convex polytope containing the weights of $\Omega^1$, there are no distinct weights $\xi_p$, $\xi_q$ of $\Omega^1$ such that $\xi_j = \frac{1}{2}(\xi_p + \xi_q)$. Then apply Thm. 4.3 \qed

**Remark** Without the ADE assumption the above two propositions are false. For example if $X = Q_3$, the weights of $\Omega^1$ are $\alpha_1$, $\alpha_1 + \alpha_2$, $\alpha_1 + 2\alpha_2$. $\alpha_1 + \alpha_2$ is shorter, indeed $2(\alpha_1 + \alpha_2)$ coincides the sum of the two vertices $(\alpha_1) + (\alpha_1 + 2\alpha_2)$. In particular $\dim \text{Hom}(\text{Sym}^2 \Omega^1, E_{2(\alpha_1+\alpha_2)})^G = 2$ and $\dim \text{Ext}^2(\mathcal{O}, E_{2(\alpha_1+\alpha_2)})^G = 1$. Hence there is no indecomposable homogeneous bundle $E$ with support $A_2$ such that $gr E = \oplus_{i=0}^2 E_{i(\alpha_1+\alpha_2)}$.

With the assumption of the two previous propositions, note that the distinguished elements in $\text{Hom} \left( E_{\lambda+p\xi_j} \otimes \Omega^1, E_{\lambda+(p+1)\xi_j} \right)^G$ which were chosen in Def. 5.5 give a
distinguished element in $\text{Hom} \left( E_\lambda \otimes \text{Sym}^k \Omega^1, E_\mu \right)^G$, which is one dimensional by Prop. 6.4. These elements allow one to define extensions of the form
\[ 0 \longrightarrow E_{\lambda+(p+1)\xi_j} \longrightarrow Z_p \longrightarrow E_{\lambda+p\xi_j} \longrightarrow 0 \]
which fit together (by Thm. 5.6(ii), since the corresponding $\text{Ext}^2$ vanish by Prop. 6.5) giving a bundle $P'$ with $\text{gr}E = \oplus_{p=0}^{k-1}E_{\lambda+p\xi_j}$ and two exact sequences (this argument is similar to the one in [Dem])
\[ 0 \longrightarrow Z' \longrightarrow P' \longrightarrow E_\lambda \longrightarrow 0 \tag{12} \]
\[ 0 \longrightarrow E_\mu \longrightarrow Z' \longrightarrow Z'/E_\mu \longrightarrow 0 \tag{13} \]

**Theorem 6.6**
\[ H^j(P') = 0 \quad \forall j \]

We need a short preparation in order to prove Thm. 6.6. Let $\lambda'$ (resp. $\mu'$) be the vertex of the Bott chamber containing $\lambda$ (resp. $\mu$). Let $A$ be the unique indecomposable bundle in the extension
\[ 0 \longrightarrow E_{\mu'} \longrightarrow A \longrightarrow E_{\lambda'} \longrightarrow 0 \]

**Proposition 6.7**
\[ H^i(A) = 0 \quad \forall i \]

**Proof** The boundary map $H^i(E_{\lambda'}) \longrightarrow H^{i+1}(E_{\mu'})$ can be seen as the cup product of class of the Schubert cell corresponding to $E_{\lambda'}$ as subbundle of $\Omega^i$ (by Hodge theory) with the hyperplane class in $H^1(\Omega^1)$ and it is nonzero by [Hi] Coroll. V 3.2. \(\square\)

**Proposition 6.8** $\text{gr}(E_{\mu'} \otimes W)$ contains only $E_{\mu}$ as direct summand with $H^* \simeq W$.

**Proof** Let $E_\alpha$ be the irreducible bundle such that $H^0(E_\alpha) = W$. The weights of $W$ as $G$-module lie in a convex polytope $P_W$ whose vertices are the reflections of $\alpha$ through the hyperplanes $H_\phi$ (for any root $\phi$ of $G$) which separate the Weyl chambers of $G$ (see [F-H] pag. 204). The weights of $E_{\mu'} \otimes W$ lie inside $P_W + \mu'$.

Let $\tilde{P}_W$ be the convex polytope whose vertices are the reflections of $g + \alpha$ through the hyperplanes $H_\phi$. Note that $P_W$ is strictly contained in $\tilde{P}_W$ and there is a natural bijective correspondence $f$ between the vertices of $P_W$ and the vertices of $\tilde{P}_W$ such that if $\beta \gamma$ is an edge of $\tilde{P}_W$ of length $d \sqrt{2}$ then $f(\beta)f(\gamma)$ is a parallel edge of $\tilde{P}_W$ of length $(d+1)\sqrt{2}$. Precisely the corresponding vertices $\beta$ and $\beta$ respectively of $\tilde{P}_W$ and $P_W$ differ by $w_\beta(g)$ for a composition of reflections $w_\beta$ defined by $\beta = w_\beta(\alpha)$. The point of $P_W$ of least distance from $\tilde{\beta}$ is $\beta$.

We have that $\mu' = w(g) - g$ for some $w$. Let $\overline{\mu} = w(\alpha)$, then $w = w_\overline{\mu}$. Then $\mu = w_\overline{\mu}(\alpha + g) - g = \overline{\mu} + \mu'$ is a vertex of $P_W + \mu'$, hence it is a maximal weight of $E_{\mu'} \otimes W$. 

24
By Bott theorem all the weights \( \nu \) such that \( H^i(E_\nu) = W \) for some \( i \) are obtained from \( \alpha \) after reflecting through the hyperplanes which separate the Bott chambers of \( G \). All these weights are some of the vertices of \( \tilde{P}_W - g \).

It is enough to show that the vertices of \( \tilde{P}_W - g \) meet \( P_W + \mu' \) only in the point \( \mu \).

The distance of \( \tilde{\beta} - g \) from \( P_W - g + (\mu' + g) = P_W - g + w_\mu(g) \) vanishes only when \( \tilde{\beta} - w_\mu(g) \in P_W \) and this happens if \( w_\beta(g) = w_\mu(g) \) (since the point of least distance between \( \tilde{\beta} \) and \( P_W \) is \( \tilde{\beta} - w_\beta(g) \)); thus \( \beta = \mu \). Then \( \tilde{\beta} - g = \beta + w_\beta(g) - g = \beta + w_\mu(g) - g = \mu + \mu' = \mu \).

**Proof of Thm. 6.6** Let now \( K \) be the submodule in \( A \otimes W \) generated by the direct summands isomorphic to \( E_\lambda \) (it can be shown that there is only one but we do not need this fact). We have the exact sequence

\[
0 \to K \to A \otimes W \to Q \to 0 \]

By Prop. 6.8 we have that \( H^j(K)^W \) and \( H^j(Q)^W \) are nonzero at most for \( j = i \) or \( j = i + 1 \).

We claim that \( grK \) contains all the direct summands isomorphic to \( E_\mu \); otherwise \( E_\mu \subset grQ \), and we would have \( H^{i+1}(Q)^W \neq 0 \), hence by Prop. 6.7 \( H^{i+2}(K)^W \neq 0 \) which is a contradiction. Hence we get \( H^j(Q)^W = 0 \) \( \forall j \) and it follows

\[
H^j(K)^W = 0 \quad \forall j
\]

At last, let \( S' \) be the quotient of \( K \) obtained restricting the quiver representation to the path joining the vertices corresponding to \( E_\lambda \) and \( E_\mu \).

We have

\[
0 \to K' \to K \to S' \to 0
\]

Now \( H^j(grK')^W = 0 \) \( \forall j \), hence \( H^j(K')^W = 0 \) \( \forall j \) and it follows \( H^j(S')^W = 0 \) \( \forall j \). Decompose \( S' \) into its irreducible components (see Thm. 6.3), we get that \( S' \) is isomorphic to the direct sum of several copies of \( P' \), by the definition of \( K \).

From the sequence (12) and Thm. 6.6 we have the isomorphism

\[
H^j(E_\lambda) \xrightarrow{\partial} H^{j+1}(Z')^W
\]

and from (13) an isomorphism

\[
H^{j+1}(E_\mu) \xrightarrow{\cong} H^{j+1}(Z')
\]

hence we get a distinguished isomorphism

\[
j_{\mu \lambda}: H^j(E_\lambda) \to H^{j+1}(E_\mu)
\]  \hspace{1cm} (14)

**Lemma 6.9** Let \( E_\lambda \) and \( E_\mu \) be in two adjacent Bott chambers with \( H^{j-1}(E_\lambda) \simeq H^{j}(E_\mu) \simeq W \). Denote by \( P \) the homogeneous bundle corresponding to the \( A_n \)-type, starting from \( E_\lambda \) and arriving in \( E_\mu \), with the same representation quiver maps as for \( E \) (it exists by Thm. 6.7 (ii) again, by the same argument as before). Then the boundary map

\[
W \otimes V_\lambda = H^{j-1}(P/V_\mu E_\mu)^W \xrightarrow{\partial} H^j(V_\mu E_\mu) = W \otimes V_\mu
\]
is the tensor product of the distinguished isomorphism in \((14)\) and the composition of the maps of the quiver representation.

**Proof** We first prove the theorem for \(P\) irreducible. We may assume \(\dim V_{\lambda+p\xi_j} = 1\) for \(0 \leq p \leq k\) and \(\lambda + k\xi_j = \mu\), moreover \(P\) defines nonzero elements in the one dimensional spaces

\[
\text{Hom} \left( V_{\lambda+p\xi_j} \otimes E_{\lambda+p\xi_j} \otimes \Omega^1, V_{\lambda+(p+1)\xi_j} \otimes E_{\lambda+(p+1)\xi_j} \right)^G =
\]

\[
= \text{Hom}(V_{\lambda+p\xi_j}, V_{\lambda+(p+1)\xi_j}) \otimes \text{Hom} \left( E_{\lambda+p\xi_j} \otimes \Omega^1, E_{\lambda+(p+1)\xi_j} \right)^G
\]

There is a natural isomorphism between

\[
\bigotimes_{i=0}^{k-1} \text{Hom} \left( V_{\lambda+p\xi_j} \otimes E_{\lambda+p\xi_j} \otimes \Omega^1, V_{\lambda+(p+1)\xi_j} \otimes E_{\lambda+(p+1)\xi_j} \right)^G
\]

and

\[
\text{Hom} \left( V_{\lambda} \otimes E_{\lambda} \otimes \text{Sym}^k \Omega^1, V_{\mu} \otimes E_{\mu} \right)^G = \text{Hom}(V_{\lambda}, V_{\mu}) \otimes \text{Hom} \left( E_{\lambda} \otimes \text{Sym}^k \Omega^1, E_{\mu} \right)^G
\]

where in \(\text{Hom}(V_{\lambda}, V_{\mu})\) we perform the composition of the quiver representation maps.

It is clear that the element obtained in \(\text{Hom}(V_{\lambda}, V_{\mu}) \otimes \text{Hom} \left( E_{\lambda} \otimes \text{Sym}^k \Omega^1, E_{\mu} \right)^G\) is enough to reconstruct \(P\).

Now we consider the two exact sequences

\[
0 \rightarrow Z \rightarrow P \rightarrow V_{\lambda} \otimes E_{\lambda} \rightarrow 0
\]

\[
0 \rightarrow V_{\mu} \otimes E_{\mu} \rightarrow Z \rightarrow P' \rightarrow 0
\]

From the first sequence we have

\[
H^j(E_{\lambda} \otimes V_{\lambda}) \otimes \partial_j H^{j+1}(Z)^W
\]

and from the second one an isomorphism (by Thm. 5.6)

\[
H^{j+1}(E_{\mu} \otimes V_{\mu}) \rightarrow H^{j+1}(Z)
\]

hence we get a map

\[
c_{\mu\lambda} : H^j(E_{\lambda} \otimes V_{\lambda}) \rightarrow H^{j+1}(E_{\mu} \otimes V_{\mu})
\]

which by the construction is the tensor product of the distinguished isomorphism \(j_{\mu\lambda}\) constructed in \((14)\) and the composition of the maps of the quiver representation, as we wanted.

In general we have \(P = \oplus P_i\) where \(P_i\) are irreducible by Thm. 6.3. Moreover we have \(V_{\lambda} = \oplus V_{\lambda}^i, V_{\mu} = \oplus V_{\mu}^i\) where every \(V_{\lambda}^i\) and \(V_{\mu}^i\) has dimension one or zero and for each \(i\) the morphism \(W \otimes V_{\lambda}^i = H^{j-1}(P_i/V_{\lambda}^i E_{\mu}) \rightarrow H^j(V_{\mu}^i E_{\mu}) = W \otimes V_{\mu}^i\) coincides again with the tensor product of the distinguished isomorphism \(j_{\mu\lambda}\) constructed in \((14)\) and the composition of the maps of the quiver representation.

We construct now maps \(H^j(gr E) \rightarrow H^{j+1}(gr E)\) by patching together the maps \(c_{\mu\lambda}\) already constructed in \((15)\), that is
**Definition 6.10**

\[ c_j := \sum c_{\mu \lambda} \]

where the sum is all over pairs \( \lambda, \mu \) in two adjacent Bott chambers and \( H^j(E_\lambda) \simeq H^{j+1}(E_\mu) \).

Although separately the isomorphism \( j_{\mu \lambda} \) in [14] and the composition of the quiver representations maps depend on the choices made in Def. [5.5] it is easy to check that their tensor product does not depend on these choices (the scalar multiple that one has to change cancel together). Moreover the construction in Def. [6.10] is functorial, that is given \( E \longrightarrow F \) we get a morphism \( H^*(grE) \longrightarrow H^*(grF) \). We see now that \( H^*(grE) \) is a complex and it gives a way to compute the cohomology.

In the case of \( \mathbb{P}^n \) this construction can be made more explicit. We have maps given by \( g_{\lambda, i}: W_\lambda \rightarrow W_{\lambda + \alpha_1 + \cdots + \alpha_i + 1} = W_\lambda' \). Let \( \lambda = \sum_{i=1}^{n} p_i \lambda_i \). Let \( p_1(\lambda) = -\sum_{j=1}^{i+1}(p_j + 1) \). Composing the maps \( W_{\lambda + j(\alpha_1 + \cdots + \alpha_i + 1)} \rightarrow W_{\lambda + (j+1)(\alpha_1 + \cdots + \alpha_i + 1)} \) for \( i \) fixed and \( j = 0, \ldots, p_i - 1 \) we get \( W_\lambda \rightarrow W_{\lambda + p_i(\lambda)(\alpha_1 + \cdots + \alpha_i + 1)} \) and we get \( W_\lambda \xrightarrow{g_{\lambda, i}} W_\lambda' \) where \( H^j(E_\lambda) = H^{j+1}(E_\lambda') \) and \( g_{\lambda, i} = \prod_{j=1}^{p_i(\lambda)} g_{\lambda + (j-1)(\alpha_1 + \cdots + \alpha_i + 1), i} \). The corresponding maps \( c_0, c_1 \) in the case of \( \mathbb{P}^2 \) are shown in the following picture.

**Remark** We warn the reader that the use of the distinguished isomorphism [14] is not a formal and superfluous addition, but it determines the correct signs which are necessary in subsequent computations. For example, assume we have \( \lambda, \mu, \nu \) in three consecutive adjacent Bott chambers such that \( H^j(E_\lambda) \simeq H^{j+1}(E_\mu) \simeq H^{j+2}(E_\nu) \), and \( \lambda, \mu', \nu \) in the same situation (at most two \( \mu \)'s exist between \( \lambda \) and \( \nu \)), it may be shown as an application of the well known relation in [C-E] III prop. 4.1 that we have the anticommutativity relation

\[ j_{\nu \mu} j_{\mu \lambda} = - j_{\nu \mu'} j_{\mu' \lambda} \]

The next theorem implies in this case that

\[ c_{\nu \mu} c_{\mu \lambda} = - c_{\nu \mu'} c_{\mu' \lambda} \]

hence it follows by the construction of \( c_{\mu \lambda} \) that the corresponding composition of quiver representation maps is commutative for the square

\[
\begin{array}{ccc}
\lambda & \longrightarrow & \mu \\
\downarrow & & \downarrow \\
\mu' & \longrightarrow & \nu
\end{array}
\]

27
taken from the Hasse quiver. In the last section about Olver maps we give more informations in the case of Grassmannians.

**Theorem 6.11** \((H^*(grE), c_*)\) is a complex and its cohomology is given by

\[
\frac{\text{Ker } c_i}{\text{Im } c_{i-1}} = H^i(E)
\]

**Proof** Let \(W\) be any irreducible \(G\)-module and let \(n = \dim X\). It is enough to compute that

\[
H^j(E)^W = \frac{\text{Ker } \left( H^i(grE)^W \xrightarrow{c_i} H^{i+1}(grE)^W \right)}{\text{Im } \left( H^{i-1}(grE)^W \xrightarrow{c_{i-1}} H^i(grE)^W \right)}
\]

We consider the filtration of \(E\) defined in the following way. \(E_1\) is defined by taking all arrows starting from any \(F \in \text{gr}E\) such that \(H^n(F)^W \neq 0\) (see Def. 5.10). \(E_2\) is defined taking all arrows starting from any \(F \in \text{gr}E\) such that \(H^n(F)^W \neq 0\). In general \(E_i\) is defined taking all arrows starting from any \(F \in \text{gr}E\) such that

\[
\oplus_{j=0}^{i-1} H^{n-j}(F)^W \neq 0
\]

We get

\[
H^j(grE_{i+1}/E_i)^W = \begin{cases} 
H^{n-i}(grE)^W & \text{if } j = n - i \\
0 & \text{if } j \neq n - i
\end{cases}
\]

hence by the spectral sequence

\[
H^j(E_{i+1}/E_i)^W = \begin{cases} 
H^{n-i}(grE)^W & \text{if } j = n - i \\
0 & \text{if } j \neq n - i
\end{cases}
\]

We have the commutative diagram

\[
\begin{array}{ccc}
H^{i-1}(E_{n-i+2}/E_{n-i+1})^W & \xrightarrow{\partial} & H^i(E_{n-i+1}/E_{n-i})^W \xrightarrow{\partial} \ldots \xrightarrow{\partial} H^i(E_{n-i})^W \\
\xrightarrow{f} & \xrightarrow{\partial} & \ldots \xrightarrow{\partial} \xrightarrow{g} H^i(grE_{n-i})^W \\
H^{i-1}(E/E_{n-i+1})^W & \xrightarrow{\partial} & H^i(E_{n-i+1}/E_{n-i})^W \xrightarrow{\partial} \ldots \xrightarrow{\partial} H^i(E_{n-i})^W \\
\end{array}
\]

where \(f\) is the projection given by the spectral sequence \(H^i(grE/E_{n-i+1})^W = 0\) and \(g\) is injective (because \(H^i(grE_{n-i})^W = 0\)). Moreover we remark that the central term is

\[
H^i(E_{n-i+1}/E_{n-i})^W = H^i(grE)^W
\]
It follows from this diagram and Thm. 6.2 that

\[ H^i(E)^W = Z_i^{n-i}/B_i^{n-i} = Ker \left( H^i(E_{n-i+1}/E_{n-i})^W \xrightarrow{\partial} H^{i+1}(E_{n-i}/E_{n-i-1})^W \right) \]

\[ \text{Im}(H^{i-1}(E_{n-i+2}/E_{n-i+1})^W) \xrightarrow{\partial} H^i(E_{n-i+1}/E_{n-i})^W \]

Now it is enough to show that the boundary map

\[ H^{i-1}(E_{n-i+2}/E_{n-i+1})^W \xrightarrow{\partial} H^i(E_{n-i+1}/E_{n-i})^W \]

induced by the exact sequence

\[ 0 \rightarrow E_{n-i+1}/E_{n-i} \rightarrow E_{n-i+2}/E_{n-i} \rightarrow E_{n-i+2}/E_{n-i+1} \rightarrow 0 \]

is the composition of the quiver representation maps tensored with \( j_{\mu} \lambda \) in (14).

Lemma 6.3 tells that this is true in the particular case of quiver representations with support \( A_m \), and we will bring back to that case. Pick \( V_{\lambda} \otimes E_{\lambda} \subset \text{gr}E_{n-i+2}/E_{n-i+1} \) and \( V_{\mu} \otimes \text{gr}E_{\mu} \subset E_{n-i+1}/E_{n-i} \) such that \( W \simeq H^{i-1}(E_{\lambda}) \simeq H^i(E_{\mu}) \).

We have to show that the composition

\[ H^{i-1}(V_{\lambda} \otimes E_{\lambda}) \xrightarrow{L} H^{i-1}(E_{n-i+2}/E_{n-i+1})^W \xrightarrow{\partial} H^i(E_{n-i+1}/E_{n-i})^W \rightarrow H^i(V_{\mu} \otimes E_{\mu}) \]

is obtained by composing the maps appearing in the quiver representation from \( V_{\lambda} \) to \( V_{\mu} \).

Consider the commutative diagram

\[
\begin{array}{cccccccc}
0 & \rightarrow & K \cap (E_{n-i+1}/E_{n-i}) & \rightarrow & E_{n-i+1}/E_{n-i} & \rightarrow & Q' & \rightarrow & 0 \\
0 & \rightarrow & K & \rightarrow & E_{n-i+2}/E_{n-i} & \rightarrow & Q & \rightarrow & 0 \\
& & E_{n-i+2}/E_{n-i+1} & \rightarrow & Q'' & \\
& & 0 & \rightarrow & 0 & \\
\end{array}
\]

where \( Q \) is the quotient of \( E_{n-i+2}/E_{n-i} \), obtained by taking all arrows arriving in \( E_{\mu} \) (see Def. 5.10) and the other bundles are defined from the diagram itself.

This diagram induces the diagram

\[
\begin{array}{cccccccc}
H^i(V_{\lambda} \otimes E_{\lambda}) & \xrightarrow{\partial} & H^i(E_{n-i+2}/E_{n-i+1})^W & \rightarrow & H^i(Q'')^W \\
& & \xrightarrow{\partial} & & \xrightarrow{\partial} & & \\
H^{i+1}(K \cap (E_{n-i+1}/E_{n-i}))^W & \xrightarrow{f} & H^{i+1}(E_{n-i+1}/E_{n-i})^W & \rightarrow & H^{i+1}(Q')^W \\
& & \xrightarrow{h} & & \xrightarrow{h} & & \\
H^{i+1}(V_{\mu} \otimes E_{\mu}) & \\
\end{array}
\]

29
The composition $hf$ is zero because $E_\mu$ is not a vertex of $K$, then the map $h$ lifts to

$$
\begin{align*}
\text{Diagram 1:} & \\
H^i(V_\lambda \otimes E_\lambda) & \xrightarrow{r} H^i(Q''_W) = H^i(V_\lambda \otimes E_\lambda) \\
H^i(E_{n-i+2}/E_{n-i+1})^W & \xrightarrow{\partial} H^i(Q''_W) \\
H^{i+1}(E_{n-i+1}/E_{n-i})^W & \xrightarrow{h} H^{i+1}(Q')^W \\
H^{i+1}(V_\mu \otimes E_\mu) & \xrightarrow{g} H^{i+1}(Q')^W
\end{align*}
$$

The last step is to construct the subbundle $P$ of $Q$ taking all arrows starting from $\lambda$ (see Def. 5.10), hence $P$ is as in the assumptions of Lemma 6.9. We get the commutative diagram

$$
\begin{align*}
\text{Diagram 2:} & \\
H^i(P/P \cap Q')^W & \simeq V_\lambda \otimes W \xrightarrow{r} H^i(Q''_W) \\
H^{i+1}(V_\mu \otimes E_\mu)^W & \xrightarrow{k} H^{i+1}(Q')^W \\
H^{i+1}(V_\mu \otimes E_\mu) & \xrightarrow{g} H^{i+1}(Q')^W
\end{align*}
$$

where $k$ and $r$ are induced by the inclusions. By the construction of $Q$ we have $H^{i+1}(grQ')^W = H^{i+1}(V_\mu \otimes E_\mu)$, hence it follows $H^{i+1}(Q')^W = H^{i+1}(V_\mu \otimes E_\mu)$ where the equality is given by $g$ and the composition $gk$ is the identity.

By Lemma 6.9 the map $\partial$ in the first column of the last diagram is the composition of the quiver representation maps tensored with $j_{\mu\lambda}$ in (14), then by chasing in the two above diagrams the claim is proved and the proof is complete.

**Remark** The fact that $(H^*(grE), c)$ is a complex should be in principle a consequence of the relation $\theta \wedge \theta = 0$. Conversely Thm. 6.11 shows that the relation $\theta \wedge \theta = 0$, which is quite difficult to be handed directly, has simpler consequences. The reader will find some informations more on this topic in the last section about Olver maps.

**Remark** The computation of cohomology allows an interpretation involving the Hasse quiver $H_X$ (see section 2). $H_X$ is obviously levelled according to Def. 5.11. Let $\lambda \rightarrow \mu \rightarrow \nu$ any composition of arrows in $H_X$. We define quadratic relations in $H_X$ asking that the sum of all the composition of two arrows between $\lambda$ and $\nu$ is zero, for all $\lambda$ and $\nu$. Now given a homogeneous bundle $E$ and an irreducible $G$-module $W$ we define a representation of $H_X$ in the following way. Let $grE = \oplus V_\lambda E_\lambda$. Given the vertex $\mu$ in $H_X$, there is a unique $\lambda$ in the Bott chamber with vertex $\mu$ such that $H^*(E_\lambda) \simeq W$. Then we associate to this vertex the $G$-module $W \otimes V_\lambda$. The maps $c_i$ of the complex $H^*(grE)$ give the maps of this representation. The direct sum of all these representations for any irreducible $G$-module give a representation of $H_X$, which satisfies the relations we have defined just because $H^*(grE)$ is a complex.
So we have constructed a functor from representations of \( \mathcal{Q}_X \) (in finite dimensional vector spaces) to representations of \( \mathcal{H}_X \) (in finite dimensional \( G \)-modules). This functor is not injective on the objects because the singular weights give zero contribution. It is easy to see that this functor is neither surjective, so that the representations which are in the image of the functor make an interesting subcategory.

We have that for any homogeneous bundle \( E \) (on \( X \) Hermitian symmetric variety) the Yoneda product with \([E] \in \text{Ext}^1(\text{gr}E, \text{gr}E)^G\) defines a complex

\[
\cdots \to H^i(\text{gr}E)^{c_i[1]} \to H^{i+1}(\text{gr}E) \to \cdots
\]

It is a complex because \( m([E]) = 0 \). We get a functor from \( P\text{-mod} \) to the (abelian) category \( \text{Kom}(G\text{-mod}) \) of complexes of \( G \)-modules

\[
E \mapsto H^*(\text{gr}E)
\]

It is straightforward to check, by using the properties of the Yoneda product, that it is an exact functor. So it is natural to ask about the cohomology of the above complex. It turns out that, in the ADE case, it gives only the first step of a filtration of the cohomology \( H^*(E) \). In fact, for any integer \( n \), we can consider the map \( H^i(\text{gr}E)^{c_i[n]} \to H^{i+1}(\text{gr}E) \) which consider the summands of \( c_i \) which are compositions of at most \( n \) arrows. The \( n = 1 \) case is given by the Yoneda product, while when \( n \) is big enough we get the whole \( c_i \). Correspondingly we have a filtration

\[
0 \subset H^i[1](E) \subset H^i[2](E) \subset \ldots \subset H^i(E)
\]

**Remark** The hypercohomology module of the complex

\[
\text{gr}E \xrightarrow{\theta_1} \text{gr}E \otimes T_X \xrightarrow{\theta_2} \text{gr}E \otimes \wedge^2 T_X \xrightarrow{\theta_3} \cdots
\]

is another interesting invariant of \( E \) (compare with [Simp] page 24). The computation in the case \( E = K_X \) shows that this should be related to the filtration above if we twist by \( O(t) \) and sum over \( t \in \mathbb{Z} \).

### 7 Moduli and Stability

For simplicity we restrict in this section to the case when \( X \) is an irreducible Hermitian symmetric variety. We consider now the moduli problem of homogeneous bundles \( E \) on \( X \) with the same \( \text{gr}E \). Any \( \mathcal{R} \)-module \( F = \oplus V_\lambda \otimes E_\lambda \) corresponds to the dimension vector \( \alpha = (\alpha_\lambda) \in \mathbb{Z}^{(\mathcal{Q}_X)_0} \) where \( \alpha_\lambda = \dim V_\lambda \). The group

\[
GL(\alpha) := \prod_{\lambda \in (\mathcal{Q}_X)_0} GL(V_\lambda)
\]

acts over

\[
\mathcal{K}(\mathcal{Q}_X, \alpha) := \oplus_{a \in (\mathcal{Q}_X)_1,} \text{Hom}(V_{ta}, V_{ha})
\]
and over the closed subvariety

\[ V_X(\alpha) \subset K(Q_X, \alpha) \]

defined by the relations in \( Q_X \). The affine quotient \( \text{Spec}(\mathbb{C}[V_X(\alpha)]^{GL(\alpha)}) \) is a single point, represented by \( F \) itself. King ([King]) considers the characters of \( GL(\alpha) \) which are given by

\[ \chi_\sigma(g) = \prod_{\lambda \in (Q_X)_0} \det(g_\lambda)^{\sigma_\lambda} \]

for \( \sigma \in \mathbb{Z}^{(Q_X)_0} \) such that \( \sum_{\lambda} \sigma_\lambda \alpha_\lambda = 0 \). The element \( \sigma \) can also be interpreted as a homomorphism \( K_0(R\text{-mod}) \to \mathbb{Z} \) which from \( E_\lambda \) gives \( \sigma_\lambda \). A function \( f \in \mathbb{C}[V_X(\alpha)] \) is called a relative invariant of weight \( \sigma \) if \( f(g \cdot x) = \sigma(g)f(x) \), and the space of such relatively invariant functions is denoted by \( \mathbb{C}[V_X(\alpha)]^{GL(\alpha), \sigma} \).

There is a natural character, that it is convenient to denote by \( \mu(\alpha) \), defined by

\[ \mu(\alpha)_\lambda = c_1(F)rk(E_\lambda) - rk(F)c_1(E_\lambda) \]

Observe that \( \mu(\alpha)(F) = \sum _\lambda \alpha_\lambda \mu(\alpha)_\lambda = 0 \). For any subrepresentation \( E' \) of \( E \in M_X(\alpha) \) let \( grE' = \oplus V'_\lambda \otimes E_\lambda \) with \( \dim V'_\lambda = \alpha'_\lambda \), then

\[ \mu(\alpha)(E') = \sum _\lambda \alpha'_\lambda \mu(\alpha)_\lambda = rkE'rkF (\mu(F) - \mu(E')) \] (16)

Then we define

\[ M_X(\alpha) := \text{Proj}(\oplus_{n \geq 0} \mathbb{C}[V_X(\alpha)]^{GL(\alpha), n\mu(\alpha)}) \]

which is projective over \( \text{Spec}(\mathbb{C}[V_X(\alpha)]^{GL(\alpha)}) \), hence it is a projective variety. The moduli space \( M_X(\alpha) \) is the GIT quotient of the open set \( V_X(\alpha)^{ss} \) of \( \chi_\mu(\alpha) \)-semistable points ([King]). Different characters give moduli spaces which are birationally equivalent to \( M_X(\alpha) \).

We collect the known results about this topic in the following propositions. We saw that \( E \) is determined by \( \theta_E \in \text{Hom}(grE, grE \otimes T_X) \) such that \( \theta_E \wedge \theta_E = 0 \) (Thm. 3.1).

**Theorem 7.1** Let \( E \) be a homogeneous bundle on \( X \) irreducible Hermitian symmetric variety and let \( \alpha \) be the dimension vector corresponding to \( grE \). The following facts are equivalent

(i) for every \( G \)-invariant subbundle \( K \) we have \( \mu(K) \leq \mu(E) \) (**equivariant semistability**)

(ii) for every subbundle \( K \) such that \( \theta_E(grK) \subset grK \otimes T_X \) we have \( \mu(K) \leq \mu(E) \) (**Higgs semistability**)

(iii) the representation \([E]\) of \( Q_X \) is \( \chi_\mu(\alpha) \)-semistable according to [King], Def. 1.1. (**quiver semistability**)

(iv) \( E \) is a \( \chi_\mu(\alpha) \)-semistable point in \( V_X(\alpha) \) for the action of \( GL(\alpha) \) ([King], Def. 2.1) (**GIT semistability**)

(v) for every subsheaf \( K \) we have \( \mu(K) \leq \mu(E) \) (**Mumford-Takemoto semistability**, see [OSS]).
Proof (i) $\iff$ (ii) follows from the fact that $F \subset E$ is $G$-invariant iff $\theta_E(grF) \subset grF \otimes T_X$. (ii) $\iff$ (iii) is straightforward from Thm. 5.9 and the remark after it and (iii) $\iff$ (iv) is proved in [King], Prop. 3.1 and Thm. 4.1. (i) $\iff$ (v) is proved in [Migl] and independently in [Ro] (this last only in the case of $P^n$, but his proof extends in a straightforward way to any $G/P$, see [Ot]).

Remark Migliorini shows in [Migl] in the analytic setting that conditions (i) to (v) are equivalent to the existence of an approximate Hermite-Einstein metric, which can be chosen invariant for a maximal compact subgroup of $G$. He also relates the stability to the image of the moment map.

Theorem 7.2 Let $E$ be a homogeneous bundle on $X$ irreducible Hermitian symmetric variety and let $\alpha$ be the dimension vector corresponding to $grE$. The following facts are equivalent

(i) for every $G$-invariant proper subbundle $K$ we have $\mu(K) < \mu(E)$ (equivariant stability)

(ii) for every proper subbundle $K$ such that $\theta_E(grK) \subset grK \otimes T_X$ we have $\mu(K) < \mu(E)$ (Higgs stability)

(iii) the representation $[E]$ of $Q_X$ is $\mu(\alpha)$-stable according to [King], Def. 1.1.

(iv) $E$ is a $\chi_{\mu(\alpha)}$-stable point in $V_X(\alpha)$ for the action of $GL(\alpha)$ ([King], Def. 1.2)

(v) $E \simeq W \otimes E'$ where $W$ is an irreducible $G$-module and for every proper subsheaf $K \subset E'$ we have $\mu(K) \leq \mu(E')$ (Mumford-Takemoto stability of $E'$, see [OSS]).

Proof (i) $\iff$ (ii) $\iff$ (iii) $\iff$ (iv) are as above. (i) $\iff$ (v) is proved in [Fa].

Remark The equivalence (i)$\iff$ (v) holds in the two previous theorems over any rational homogeneous variety $X$ (for any slope $\mu_a$).

Remark Thm. 7.1 and Thm. 7.2 extend in a straightforward way to any $\sigma: K_0(R-mod) \to Z$ such that $\sigma(grE) = 0$ at the place of $\mu(\alpha)$.

Remark Thm. 7.2 shows that Mumford-Takemoto stability is a stronger condition than stability in $Q_X$. The Euler sequence on $P^n$ just explains this fact. Indeed $O \otimes V$ corresponds to a stable representation of $Q_{P^n}$, but it is not a Mumford-Takemoto stable bundle. The points in $M_X(\alpha)$ parametrize $S$-equivalent classes of semistable homogeneous bundles $E$ with the same $grE$ corresponding to $\alpha$. The closed orbits in $V_X(\alpha)^{ss}$ correspond to direct sums $\oplus_j W_j \otimes F_j$ where $W_j$ are irreducible $G$-modules and $F_j$ are Mumford-Takemoto stable homogeneous bundles.

When $E$ is a Mumford-Takemoto homogeneous stable bundle, we get $W = C$ in condition (v) and an open set containing the corresponding point in $M_X(\alpha)$ embeds in the corresponding Maruyama scheme of stable bundles (see the construction of families in §5 of [King]). The tangent space at this point is $H^1(EndE)^G$.

Observe that the irreducible bundles do not deform as homogeneous bundles and their corresponding moduli space in the sense above is a single point. (see Cor. 4.4).
Example 7.3  We describe an example of a homogeneous bundle on \( \mathbb{P}^2 \) with a continuous family of homogeneous deformations. This example appears already in [Hi1], ex. 1.8.7 and prop. 4.2.4.

Such example is \( E = \text{Sym}^2 Q(-1) \otimes S^2 V \) of rank 24. It is easy to compute that \( H^1(\text{End} E)^G = \mathbb{C} \). The corresponding representation of the quiver associates to

\[
\begin{array}{c}
\mathcal{O} \\
\downarrow \\
Q(-2) \\
\downarrow \\
\text{Sym}^2 Q(-1) \\
\downarrow \\
\text{Sym}^3 Q \\
\downarrow \\
\text{Sym}^3 Q(-3) \\
\downarrow \\
\text{Sym}^4 Q(-2)
\end{array}
\]

the diagram

\[
\begin{array}{c}
\mathbb{C} \\
\downarrow \begin{array}{c} f_1 \\ f_2 \end{array} \\
\mathbb{C}^2 \\
\downarrow \begin{array}{c} f_3 \\ f_4 \end{array} \\
\mathbb{C} \\
\downarrow \\
\mathbb{C}
\end{array}
\]

The 4 arrows starting or ending in the middle \( \mathbb{C}^2 \) determine 4 one dimensional spaces (two kernel and two images) which correspond to 4 marked points in \( \mathbb{P}^1 \). The cross-ratio of these 4 points describes the deformation. The generic deformation is Mumford-Takemoto stable. If we fix the dimension vector \( \alpha = (1, 1, 1, 2, 1, 1, 1) \) according to the diagram above, then

\[ M_{\mathbb{P}^2}(\alpha) = \mathbb{P}^1 \]

Indeed the character \( \mu(\alpha) \) is \( 72(0, -1, 1, 0, -2, 2, 0) \). We can divide by 72 and the coordinate ring

\[ \bigoplus_{n \geq 0} \mathbb{C}[V_X(\alpha)]^{GL(\alpha), n\mu(\alpha)} \]

is generated by

\[ S = (f_4 f_1)(f_3 f_2)^2 \quad \text{and} \quad T = (f_4 f_2)(f_3 f_2)(f_3 f_1) \]

(both correspond to \( n = 1 \)). If we do not divide by 72 then the two generators are \( S^{72} \) and \( T^{72} \).

There are three distinguished points. The first one (corresponding to \( S = 0 \)) when \( \text{Im} f_1 = \text{Ker} f_4 \). In this case there are three different orbits where the \( S \)-equivalence class contains \( \mathcal{O} \) as direct summand. The second one (corresponding to \( S = T \)) when \( \text{Im} f_1 = \text{Im} f_2 \) or when \( \text{Ker} f_3 = \text{Ker} f_4 \). In this case there are three different orbits where the \( S \)-equivalence class contains \( \text{Sym}^2 Q(-1) \) as direct summand. The third one (corresponding to \( T = 0 \)) when \( \text{Im} f_1 = \text{Ker} f_3 \) or when \( \text{Im} f_2 = \text{Ker} f_4 \). Also in this case there are three different orbits where the \( S \)-equivalence class contains \( \text{ad} V \) as direct summand. Observe that \( \text{Im} f_2 = \text{Ker} f_3 \) gives a nonstable situation where the middle row \( \mathbb{C} \overset{f_1}{\rightarrow} \text{Im} f_2 \overset{f_3}{\rightarrow} \mathbb{C} \) destabilizes.

34
There are other two particular points in $M_{\mathbb{P}^1}(\alpha)$ which correspond respectively to $\text{Sym}^2 Q(-1) \otimes S^2 V$ and to $\text{ad} C$ where $C$ is the rank 5 exceptional bundle defined by the sequence

$$0 \rightarrow Q(-1) \rightarrow C \rightarrow \text{Sym}^2 Q \rightarrow 0$$

**Remark** It seems an interesting open questions to understand when $M_X(\alpha)$ is nonempty or irreducible.

8 Olver maps and explicit relations for Grassmannians

The aim of this section is to make explicit in the case of Grassmannians the relations coming from $\theta \wedge \theta = 0$ and the corresponding complex $H^*(\text{gr} E)$.

We restrict to the case $G = \text{SL}(V)$. Let $a$ (resp. $a', a''$) be the Young diagram associated to $\lambda$ (resp. $\lambda', \lambda''$), so that $S^a V$ is the representation with maximal weight $\lambda$. We have that $a'$ is obtained adding one box to $a$ and we have the Pieri maps $S^{a'} V \otimes V \rightarrow S^a V$. These maps are defined up to a nonzero scalar multiple. Olver gave in the unpublished preprint [Ol] a nice description of these maps. This description was used in [D], then a proof appeared in [M-O], in the more general setting of skew Young diagrams.

It is well known that $S^a V$ can be obtained as a quotient of $\text{Sym}^a V := \text{Sym}^{a_1} V \otimes \ldots \otimes \text{Sym}^{a_n} V$ (see [DC-E-P] or [F-H]), namely there is the quotient map (D 2.6)

$$\rho_a: \text{Sym}^a V \rightarrow S^a V$$

Olver’s idea is to consider the Pieri maps at the level of $\text{Sym}^a V$ and then factor through the quotient.

We follow here [D], where a different notation is used, in particular $\text{Sym}^a V$ in [D] is ours $\text{Sym}^a V$. We refer to [D] for the definition of the linear map $\chi_a': \text{Sym}^{a'} V \rightarrow \text{Sym}^a V \otimes V$. This is called an Olver map.

**Theorem 8.1 (Olver, [D] thm. 2.14)** Consider the diagram

$$
\begin{array}{ccc}
\text{Sym}^{a'} V & \xrightarrow{\chi_a'} & \text{Sym}^a V \otimes V \\
\downarrow{\rho_a'} & & \downarrow{\rho_a \otimes 1} \\
S^{a'} V & \quad & S^a V \otimes V
\end{array}
$$

Then $\chi_a'(\ker \rho_a') \subseteq \ker(\rho_a \otimes 1)$ and $\chi_a'$ induces the nonzero $\text{SL}(V)$-equivariant

$$\psi_a': S^{a'} V \rightarrow S^a V \otimes V$$

making the above diagram commutative.

A tableau on the Young diagram $a$ is a numbering of the boxes with the integers between 1 and $n+1$. A tableau is called *standard* if the rows are weakly increasing from the left to the right and the columns are strictly increasing from the top to the bottom. The *content* of a tableau $T$ is the function $C_T: \{1, \ldots, n\} \rightarrow \mathbb{N}$ such that
$C_T(p)$ is the number of times $p$ occurs in $T$. After a basis $e_1, \ldots, e_{n+1}$ of $V$ has been fixed, to any tableau $T$ is associated in the natural way a tensor $T^S$ in $\text{Sym}^aV$ by symmetrizing the basis vectors labelled by each row. The eigenvectors for the action of the diagonal subgroup of $SL(V)$ over $\mathcal{S}^aV$ correspond to $\rho_a(T^S)$ with $T$ chosen among the standard tableau. They form a basis of $\mathcal{S}^aV$.

Let $K^a$ be the tableau obtained by filling the $i$-th row with entries equal to $i$ (it is called canonical in [DC-E-P]); $K^a$ is the only standard tableau among those with the same content. The projection $\rho_a(K^{aS})$ is a maximal eigenvector for $\mathcal{S}^aV$ and we denote it by $\kappa^a$. Let $a'$ be obtained from $a$ by adding a box to the $i$-th row and let $a''$ be obtained from $a'$ by adding a box to the $j$-th row. Consider the map $\chi^a_{a''}: \text{Sym}^{a''}V \rightarrow \text{Sym}^aV \otimes V \otimes V$ defined as the composition

\[
\text{Sym}^{a''}V \xrightarrow{\chi^a_{a''}} \text{Sym}^aV \otimes V \xrightarrow{\chi^a} \text{Sym}^aV \otimes V \otimes V
\]

$\chi^a_{a''}$ also induces the nonzero $SL(V)$-equivariant morphism

\[
\psi^a_{a''}: \mathcal{S}^{a''}V \rightarrow \mathcal{S}^aV \otimes V \otimes V
\]

Let $K^a_{i,j}$ be the tableau on $a'$ obtained by adding a box filled with $j$ at the $i$-th row of $K^a$. We denote by $\kappa^a_{i,j}$ the element $\rho_a(K^a_{i,j})$

**Proposition 8.2** (i) If $i > j$ then

\[
\psi^a_{a'}(\kappa^a) = (a_j + 1)\kappa^a' \otimes e_j + \sum_{h \neq j, i} \tau_h \otimes e_h
\]

for some $\tau_h$.

(ii) If $i = j$ then

\[
\psi^a_{a'}(\kappa^a) = (a_j + 2)\kappa^a' \otimes e_j + \sum_{h \neq j} \tau_h \otimes e_h
\]

for some $\tau_h$.

(iii) If $i < j$ then

\[
\psi^a_{a'}(\kappa^a) = \left(\frac{(a_j + 1)(a_i + 1)}{a_i - a_j + j - i} \kappa_{i,j}' + \tau\right) \otimes e_i + (a_j + 1)\kappa^a' \otimes e_j + \sum_{h \neq i, j} \tau_h \otimes e_h
\]

for some $\tau$, $\tau_h$, where $\psi^a_{a'}(\tau)$ has zero coefficient in $e_j \otimes \kappa^a$.

**Proof** In (i) and (ii) the summand $\kappa^a' \otimes e_j$ is obtained with $J = (0, j)$ (see [D2.12]). In (iii) the summand $\kappa_{i,j}' \otimes e_i$ is obtained with $J = (0, i, j)$ while the summand $\kappa^a' \otimes e_j$ is obtained with $J = (0, j)$.

**Corollary 8.3** (i) If $i > j$ then

\[
\psi^a_{a'}(\kappa^a) = (a_i + 1)(a_j + 1)\kappa^a \otimes e_i \otimes e_j +
\]
... (linear combination of other basis vectors different from \( \kappa^a \otimes e_j \otimes e_i \))

(ii) If \( i = j \) then

\[
\psi^{a''}_{a}(\kappa^a) = (a_j + 1)(a_j + 2) \kappa^a \otimes e_j \otimes e_j + \ldots \text{(linear combination of other basis vectors)}
\]

(iii) If \( i < j \) then

\[
\psi^{a''}_{a}(\kappa^a) = (a_i + 1)(a_j + 1) \kappa^a \otimes \left( e_i \otimes e_j - \frac{1}{a_i - a_j + j - i} e_j \otimes e_i \right) + \ldots
\]

... (linear combination of other basis vectors)

**Remark** The case (i) of Cor. 8.3 does not appear if \( i = j + 1 \) and \( a_i = a_j \), in such a case \( a'' \) is obtained from \( a \) by adding two boxes to the same column, and the only possibility is to add first the highest box and then the lowest one.

Now consider a bundle \( E_\lambda = S^\alpha U \otimes S^\beta Q^s(t) \) (as in section 5) in the Grassmannian \( \text{Gr}(P^k, P^n) \) where \( \lambda = \sum_{i=1}^n c_i \lambda_i \). Let \( p, q \in \mathbb{N} \).

Let

\[
n_{p,q} := - \sum_{i=(p-1)}^{q-1} \alpha_{k+1+i} \\
\lambda_{p,q} := \lambda + n_{p,q} \\
\lambda_q := \lambda_{1,q} = \lambda - \sum_{i=0}^{q-1} \alpha_{k+1+i}
\]

We denote the corresponding morphism as

\[
m_{\lambda,p,q} : E_\lambda \otimes \Omega^1 \rightarrow E_{\lambda_{p,q}}
\]

normalized according to Def. 5.5.

Then \( E_{\lambda,p,q} = S^\alpha U \otimes S^\beta Q^s(t) \) where \( \alpha' \) is obtained from \( \alpha \) by adding a box to row \( p \) and \( \beta' \) is obtained from \( \beta \) by adding a box to row \( q \).

In the following proposition we make the relations (see Def. 5.7) explicit for \( Q_{\text{Gr}(P^k, P^n)} \).

We consider \( E_{\lambda'} = S^\alpha U \otimes S^\beta Q^s(t) \) where \( \alpha'' \) is obtained from \( \alpha \) by adding two box to rows \( p_1, p_2 \) and \( \beta'' \) is obtained from \( \beta \) by adding two boxes to rows \( q_1, q_2 \). If \( p_1 = p_2 \) and \( q_1 = q_2 \) then \( \text{Ext}^2(E_\lambda, E_{\lambda''})^G = 0 \). By the symmetry we may assume \( p_1 \leq p_2, q_1 < q_2 \). Let

\[
\tilde{p} := \sum_{i=p_1}^{p_2-1} c_{k+1-i} + p_2 - p_1 = \alpha_{p_1} - \alpha_{p_2} + p_2 - p_1
\]

\[
\tilde{q} := \sum_{i=q_1}^{q_2-1} c_{k+1+i} + q_2 - q_1 = \beta_{q_1} - \beta_{q_2} + q_2 - q_1
\]

Note that \( \tilde{p} = 1 \) if and only if \( p_2 = p_1 + 1 \) and \( c_{k+1-p_1} = 0 \). In the same way \( \tilde{q} = 1 \) if and only if \( q_2 = q_1 + 1 \) and \( c_{k+1+q_1} = 0 \).
Proposition 8.4 (Explicit relations for $Q_{Gr}(P^k, P^n)$)

(i) If $p_1 < p_2$, we have the subcases

(i1) $\tilde{p} \neq 1$, $\tilde{q} \neq 1$; in this case we have the two equations

$$g_{\lambda_{p_1,q_1},p_2,q_2} g_{\lambda,\lambda_{p_1,q_1}} \left( \frac{1}{q} - \frac{1}{p} \right) - g_{\lambda_{p_1,q_2},p_2,q_1} g_{\lambda,\lambda_{p_1,q_1}} + g_{\lambda_{p_1,q_1},p_2,q_2} g_{\lambda,\lambda_{p_1,q_1}} = 0$$

$$g_{\lambda_{p_1,q_1},p_2,q_2} g_{\lambda,\lambda_{p_1,q_1}} \left( \frac{1}{p} - 1 \right) +$$

$$-g_{\lambda_{p_1,q_2},p_2,q_1} g_{\lambda,\lambda_{p_1,q_1}} \left( \frac{1}{pq} - 1 \right) + g_{\lambda_{p_2,q_2},p_2,q_1} g_{\lambda,\lambda_{p_1,q_1}} = 0$$

(ii) $\tilde{p} = 1$ and $\tilde{q} \neq 1$; in this case $\lambda_{p_2,q_1}, \lambda_{p_2,q_2}$ do not exist and we have the single equation

$$g_{\lambda_{p_1,q_1},p_2,q_2} g_{\lambda,\lambda_{p_1,q_1}} \left( \frac{1}{q} - 1 \right) - g_{\lambda_{p_1,q_2},p_2,q_1} g_{\lambda,\lambda_{p_1,q_1}} = 0$$

(iii) $\tilde{p} \neq 1$ and $\tilde{q} = 1$; in this case $\lambda_{p_1,q_2}, \lambda_{p_2,q_2}$ do not exist and we have the single equation

$$g_{\lambda_{p_1,q_1},p_2,q_2} g_{\lambda,\lambda_{p_1,q_1}} \left( 1 - \frac{1}{p} \right) + g_{\lambda_{p_1,q_2},p_2,q_2} g_{\lambda,\lambda_{p_1,q_1}} = 0$$

(iv) $\tilde{p} = \tilde{q} = 1$; in this case only $\lambda_{p_1,q_1}$ survives and there are no equations at all. Hille counterexample (see Example 5.11) fits this case.

(ii) If $p_1 = p_2$ we have the subcases

(ii1) $\tilde{q} \neq 1$; in this case we have the equation

$$g_{\lambda_{p_1,q_1},p_2,q_2} g_{\lambda,\lambda_{p_1,q_1}} \left( \frac{1}{q} - \right) g_{\lambda_{p_1,q_2},p_2,q_1} g_{\lambda,\lambda_{p_1,q_1}} = 0$$

(ii2) $\tilde{q} = 1$; in this case we have the equation

$$g_{\lambda_{p_1,q_1},p_2,q_2} g_{\lambda,\lambda_{p_1,q_1}} = 0$$

Proof Let $p_1 < p_2$. Consider that

$$m_{\lambda_{p_1,q_1},p_2,q_2} \land m_{\lambda,\lambda_{p_1,q_1}} (n_{p_1,q_2} \land n_{p_2,q_1} \otimes v_\lambda) = m_{\lambda_{p_1,q_1},p_2,q_2} (n_{p_1,q_2} \otimes m_{\lambda,\lambda_{p_1,q_1}} (n_{p_2,q_1} \otimes v_\lambda)) +$$

$$-m_{\lambda_{p_1,q_1},p_2,q_2} (n_{p_2,q_1} \otimes m_{\lambda,\lambda_{p_1,q_1}} (n_{p_1,q_2} \otimes v_\lambda)) = \left( -\frac{1}{p} + \frac{1}{q} \right) v_\lambda$$

(the last equality by Cor. 8.3). In the same way if $\tilde{q} \neq 1$

$$m_{\lambda_{p_1,q_1},p_2,q_2} \land m_{\lambda,\lambda_{p_1,q_2}} (n_{p_1,q_2} \land n_{p_2,q_1} \otimes v_\lambda) = -v_\lambda$$

Moreover if $\tilde{p} \neq 1$

$$m_{\lambda_{p_2,q_1},p_2,q_2} \land m_{\lambda,\lambda_{p_2,q_1}} (n_{p_1,q_2} \land n_{p_2,q_1} \otimes v_\lambda) = v_\lambda$$

38
Besides

\[ m_{\lambda, p_2-q_2, p_1, q_1} \land m_{\lambda, p_2, q_2} (n_{p_1, q_2} \land n_{p_2, q_1} \otimes v_{\lambda}) = 0 \]

Now by computing the left side of the relation \( 6 \) on \( n_{p_1, q_1} \land n_{p_2, q_2} \otimes v_{\lambda} \) we get the first equation of (i1).

In the same way, computing the left side of the relation \( 6 \) on \( n_{p_1, q_1} \land n_{p_2, q_2} \otimes v_{\lambda} \) we get the second equation of (i1). The other subcases of (i) are particular cases of (i1). (ii) is analogous.

Remark The number of equations obtained in Prop. 8.4 measures exactly the dimension of \( \text{Ext}^2(E_{\lambda}, E_{\lambda}'')^G \), which can be 2, 1, or 0. An interesting consequence of Prop. 8.4 is that (with the assumptions in (i)) there is no indecomposable homogeneous bundle on \( \text{Gr}(P^k, P^n) \) such that its quiver representation has support equal to the parallelogram with vertices \( E_{\lambda}, E_{\lambda_{p_1, q_1}}, E_{\lambda_{p_2, q_1}}, E_{\lambda''} \). The first consequence is that on \( \text{Gr}(P^1, P^3) \) every homogeneous bundle \( E \) such that \( grE = \Omega^1 \oplus \Omega^2 \oplus \Omega^3 \) decomposes. On the other hand an indecomposable homogeneous bundle such that its quiver representation has support equal to the parallelogram with vertices \( E_{\lambda}, E_{\lambda_{p_1, q_1}}, E_{\lambda_{p_2, q_2}}, E_{\lambda''} \) exists if and only if \( \tilde{p} = \tilde{q} \). The first nontrivial example is, on the Grassmannian of lines in \( P^3 = P(V) \), the cohomology bundle \( E \) of the monad

\[ O(-2) \rightarrow S^{2,2}V \rightarrow O(2) \]

which has \( grE = O \oplus \Omega^1 \oplus \Omega^1(2) \oplus (\text{Sym}^2U \otimes \text{Sym}^2Q) \).

Corollary 8.5 (Explicit relations for \( Q_{P^n} \)) In the case of \( P^n \) the category of homogeneous bundles is equivalent to the category of representations of \( Q_{P^n} \) with the commutativity relations.

Proof Put \( p_1 = p_2 = 1 \) in Prop. 8.4 and get

\[ g_{\lambda, q_1, q_2} g_{\lambda, q_1} \left( \frac{1 + \tilde{q}}{\tilde{q}} \right) - g_{\lambda, q_2, q_2} g_{\lambda, q_2} = 0 \]

unless \( \tilde{q} = 1 \).

Denoting

\[ h_{\lambda, i} := (c_i + 1)(c_{i-1} + c_i + 2) \cdots (c_2 + \ldots + c_i + i - 1) f_{\lambda, i} \]

we get a functor from the quiver \( Q_{P^n} \) with the relations that we have defined to the same quiver but with the commutativity relations

\[ h_{\lambda, q_1, q_2} h_{\lambda, q_1} - h_{\lambda, q_2, q_1} h_{\lambda, q_2} = 0 \]

This functor gives the desired equivalence.
