Abstract

The type III interferon (IFN) receptor is preferentially expressed by epithelial cells. It is made of two subunits: IFNLR1, which is specific to IFN-lambda (IFN-λ) and IL10RB, which is shared by other cytokine receptors. Human hepatocytes express IFNLR1 and respond to IFN-λ. In contrast, the IFN-λ response of the mouse liver is very weak and IFNLR1 expression is hardly detectable in this organ. Here we investigated the IFN-λ response at the cellular level in the mouse liver and we tested whether human and mouse hepatocytes truly differ in responsiveness to IFN-λ. When monitoring expression of the IFN-responsive Mx genes by immunohistofluorescence, we observed that the IFN-λ response in mouse livers was restricted to cholangiocytes, which form the bile ducts, and that mouse hepatocytes were indeed not responsive to IFN-λ. The lack of mouse hepatocyte response to IFN-λ was observed in different experimental settings, including the infection with a hepatotropic strain of influenza A virus which triggered a strong local production of IFN-λ. With the help of chimeric mice containing transplanted human hepatocytes, we show that hepatocytes of human origin readily responded to IFN-λ in a murine environment. Thus, our data suggest that human but not mouse hepatocytes are responsive to IFN-λ in vivo. The non-responsiveness is an intrinsic property of mouse hepatocytes and is not due to the mouse liver micro-environment.

Introduction

The type III interferon (IFN) family was discovered about 10 years ago by two independent groups [1,2]. Three type III IFN subtypes have been described, IFN-λ1, IFN-λ2 and IFN-λ3, also named IL29, IL28A and IL28B, respectively [1,2]. A fourth IFN-λ-coding sequence was found in some allelic variants [3]. In mice, only IFN-λ2 and IFN-λ3 are expressed since IFN-λ1 is a pseudogene [1,2,4]. Type III IFNs signal through a heterodimeric receptor composed of the IFN-λ-specific IFNLR1 chain and the IL10RB chain which is shared by other IL-10 cytokine family members [1,2,5]. Although type I and type III IFNs use distinct receptors, they both signal via the Jak-STAT pathway, leading to phosphorylation of STAT1 and STAT2 and to formation of the ISGF3 complex by association with IRF9. Consequently, type I and type III IFNs upregulate the same group of IFN-stimulated genes (ISGs), which code for proteins such as Mx or OAS that inhibit replication of viruses. IFN-λ expression is specific to IFN-λ receptors (IFNAR), which are made of the IFN-λ receptor composed of IFNAR1, which is specific to IFN-α/β, and IFNAR2, which is shared by other cytokine receptors. Human hepatocytes express IFNAR1 and respond to IFN-α/β. In contrast, the IFN-λ response of the mouse liver is very weak and IFNLR1 expression is hardly detectable in this organ. Here we investigated the IFN-λ response at the cellular level in the mouse liver and we tested whether human and mouse hepatocytes truly differ in responsiveness to IFN-λ. When monitoring expression of the IFN-responsive Mx genes by immunohistofluorescence, we observed that the IFN-λ response in mouse livers was restricted to cholangiocytes, which form the bile ducts, and that mouse hepatocytes were indeed not responsive to IFN-λ. The lack of mouse hepatocyte response to IFN-λ was observed in different experimental settings, including the infection with a hepatotropic strain of influenza A virus which triggered a strong local production of IFN-λ. With the help of chimeric mice containing transplanted human hepatocytes, we show that hepatocytes of human origin readily responded to IFN-λ in a murine environment. Thus, our data suggest that human but not mouse hepatocytes are responsive to IFN-λ in vivo. The non-responsiveness is an intrinsic property of mouse hepatocytes and is not due to the mouse liver micro-environment.

Abstract

The type III interferon (IFN) receptor is preferentially expressed by epithelial cells. It is made of two subunits: IFNLR1, which is specific to IFN-lambda (IFN-λ) and IL10RB, which is shared by other cytokine receptors. Human hepatocytes express IFNLR1 and respond to IFN-λ. In contrast, the IFN-λ response of the mouse liver is very weak and IFNLR1 expression is hardly detectable in this organ. Here we investigated the IFN-λ response at the cellular level in the mouse liver and we tested whether human and mouse hepatocytes truly differ in responsiveness to IFN-λ. When monitoring expression of the IFN-responsive Mx genes by immunohistofluorescence, we observed that the IFN-λ response in mouse livers was restricted to cholangiocytes, which form the bile ducts, and that mouse hepatocytes were indeed not responsive to IFN-λ. The lack of mouse hepatocyte response to IFN-λ was observed in different experimental settings, including the infection with a hepatotropic strain of influenza A virus which triggered a strong local production of IFN-λ. With the help of chimeric mice containing transplanted human hepatocytes, we show that hepatocytes of human origin readily responded to IFN-λ in a murine environment. Thus, our data suggest that human but not mouse hepatocytes are responsive to IFN-λ in vivo. The non-responsiveness is an intrinsic property of mouse hepatocytes and is not due to the mouse liver micro-environment.
response in the liver [14]. Consistent with these data, Pagliacetti and colleagues found that IFN-λ2 only weakly inhibited HBV replication when injected intravenously in HBV-transgenic mice, as compared to the inhibition observed with IFN-β or IFN-γ [15].

As a first approach to more thoroughly investigate the IFN-λ response in the mouse liver, we used mice carrying a functional Mx1 gene [16] that permit measuring IFN responses with high sensitivity at the single cell level [8,17]. Using this system, we found that although mouse hepatocytes can respond to IFN-λ, they do not respond to IFN-γ. Instead, we observed a strong IFN-λ response in cholangiocytes, the epithelial cells forming the bile ducts. Finally, using chimeric mice that were transplanted with human hepatocytes [18], we demonstrated that human but not mouse hepatocytes are responsive to IFN-λ under identical experimental conditions in vivo.

Materials and Methods

Animal Experiments

Ethics statement: Handling of mice (agreement LA1230472) and experimental procedures were conducted in accordance with the EEC directive 86/609/CEE and the related Belgian law of April 6th 2010. The study and protocol used in this study were approved by the ethics committee of the University of Louvain under the agreement # 2010/UCL/MD/031.

Six to 9 week-old C57BL/6 mice carrying a functional Mx1 gene (B6.A2G-Mx1, designated Mx-wt) were from the breeding colony at the University of Freiburg, Germany. B6.A2G-Mx1 mice either lacking a functional type I IFN receptor (designated Mx-IIFNAR10/0), a functional type III IFN receptor (designated Mx-IIFNLRI0/0) or both (designated Mx-IIFNAR10/0 IIFNLRI0/0) were described previously [13]. 12 to 13 week-old chimeric human liver-uPA-SCID mice were generated in the animal facility of the Faculty of Medicine and Health Sciences at the Ghent University. Briefly, 2-week old transgenic SCID mice overexpressing the albumin promoter were xenografted with about 1 million primary human hepatocytes (donor HH223; BD Biosciences, Erembodegen, Belgium) as previously described [18]. Engraftment and repopulation of the mouse liver by the transplanted human hepatocytes was evaluated by quantifying the amount of human albumin present in the mouse plasma (Bethyl Laboratories, Montgomery, Tx).

doi:10.1371/journal.pone.0087906.t001

Phasms

All plasmids used in this work are pcDNA3 (Invitrogen) derivatives. The primer sequences used in this work are presented in table 1. The plasmids pcDNA3-muIFNα2A, pcDNA3-muIFN-β6T and pcDNA3-muIFNα3 were described previously [8,19]. HuIFN-α3 was cloned into TOPO-huIFNα3 (Source Bioscience) into pcDNA3 (Invitrogen). The PCR-amplified fragment was cloned into pcDNA3 using the HindIII and Asp718 restriction sites. HuIFN-α2 was amplified from HeLa cells DNA. The PCR-amplified fragment was cloned into pcDNA3 using EcoRI and Not restriction sites.

Virus Infection

TURH (H7/N1) virus is a mouse-adapted hepatotropic variant of influenza virus strain A/TURKEY/England 63 (Havl, Nav3) [20]. 8–9 week-old Mx-IIFNAR10/0 and Mx-IIFNLRI0/0 mice were used in this experiment. For each genotype, twelve mice were infected intraperitoneally with 10^7 plaque-forming units (pfu) of TURH. Livers were collected at 24 h (n = 2) and 48 h (n = 6) post infection. Four mice, used as negative control, received phosphate buffer saline (PBS) and were sacrificed after 48 h.

DNA Electroinjection and Recombinant IFN Administration

Mx-wt mice or chimeric human liver uPA-SCID mice were anesthetized and electroinjected as previously described [8]. Briefly, 10 μg of endotoxin-free plasmid DNA (Quiagen endofree) suspended in PBS, were injected in a volume of 25 μl in the left and right tibialis anterior muscles. DNA was electroporated using
Lack of IFN-λ Response in Mouse Hepatocytes

a Cliniporator system (Cliniporator, IGEA, Carpi, Italy). Mice were then woken up by intraperitoneal injection of 250 μl of Atipamezol 500 μg/ml (Antisedan) and kept in an insulator for 7 days prior to sacrifice and organ harvest. For recombinant IFN administration, 6–8 week-old Mx-IFNAR10/0, Mx-IFNLR10/0 or Mx-IFNAR10/0 IFNLR10/0 were treated subcutaneously with 100 μl of PBS containing either 1 μg of cross-reactive human

IFN-α/B/D [21], 1 μg of recombinant mouse IFN-λ2 (PeproTech), or a mixture of both cytokines.

RNA Extraction and Quantitative Real-time Reverse Transcription (RT-qPCR)

Mice were anesthetized and perfused intracardially with PBS before organs harvest. RNA was isolated from organs, reverse-transcribed and subjected to quantitative RT-PCR (RT-qPCR) as
previously described [22], using SybrGreen and the MyIQ™ apparatus (Biorad). The primer sequences used are described in Table 1. Standards consisted of 10-fold dilutions of known concentrations of a plasmid carrying a PCR fragment from cDNA encoding the influenza A virus matrix protein M1, OASl2, OAS1, MxA or β-actin. All RT-qPCR results were normalized to β-actin cDNA levels in a sample.

**Immunohistofluorescence**

Mx-wt mice or chimeric human liver-uPA-SCID mice were anesthetized and perfused intracardially with PBS containing 1–

4% of paraformaldehyde (PFA) before organ harvest. Freshly collected organs were immersed in 4% buffered formic acid for 4 h at room temperature and then paraffin-embedded. Tissues were cut at 4 μm with a microtome and sections were placed on SuperFrost Plus slides, dried at 37°C overnight, and processed by standard methods for immunohistochemistry. Briefly, tissue sections were deparaffinized, permeabilized for 5 min in PBS/0.1% Triton X-100 and washed in PBS. Unmasking of antigens was done by treating tissue sections for 60 min at 97°C in 10 mM sodium citrate buffer (pH 5.8) before blocking with Antibody Diluent with Background Reducing Components (Dako #S3022). Primary and secondary antibodies were diluted in blocking solution.

The following primary antibodies and dilutions were used: rabbit polyclonal anti-influenza virus (FLUAV #178, Freiburg University) at 1:1000, rabbit polyclonal anti-mouse Mx1 at 1/200 (AP5#2771, [23]), mouse monoclonal anti-human HNF4α/NR2A1 (HNF4) at 1/300 (R&D Systems #PP-H1415-00), mouse monoclonal anti-pan cytokeratin at 1/500 (Sigma, #C5992), mouse monoclonal anti-human MxA at 1/2500 (#M143 [24]), rabbit polyclonal anti-human MxA at 1/2500 (#41, Freiburg University), mouse monoclonal anti-human cytokeratin 18 (Clone DC 10, Dako, # M 7010), rabbit monoclonal anti-human albumin (Merek Millipore, #126584).

Secondary antibodies were AlexaFluor conjugates (Invitrogen). The following antibodies and dilutions were used: goat anti-mouse AlexaFluor 594 cross-adsorbed at 1/400 (HNF4 and Cytokeratin immunostainings), goat anti-rabbit AlexaFluor 594 at 1/400 (albumin immunostainings), goat anti-rabbit HRP at 1/100 (influenza virus, Mx1 and MxA (#41) immunostainings) and goat anti-mouse HRP at 1/100 (MxA (#143) immunostainings). For influenza A virus, Mx1 and MxA immunostainings, detection required amplification using tyramide signal amplification (TSA) (#NEL701001KT and NEL702001KT, PerkinElmer). Nuclei were stained with Hoechst33258 (Roche) or DAPI (Vectorshied H-1200, Vector Laboratories).

Statistical Analysis
Data were analyzed with Prism version 4.0c using one-tailed Mann-Whitney U test. P values ≤0.05 were considered significant.

Results
Cholangiocytes but not Hepatocytes Respond to IFN-λ, in Mouse Livers
Previously published data from in vivo experiments show a very weak IFN-λ response in the mouse liver [8,13]. As a first approach to identify IFN-λ-responsive cells in mouse liver, we performed Mx1 immunolabelings on liver sections from mice that were electroinjected with IFN expression vectors. We used the previously described mice that carry a functional Mx1 gene so that the IFN response can be detected by immunohistochemistry. We used antibodies detecting Mx1, which gives a characteristic nuclear signal. Mx-IFNLR10/0, Mx-IFNAR10/0 or Mx-IFNAR10/0 IFNLR10/0 mice were electroinjected in the tibialis anterior muscle with IFN-λ or IFN-β expression vectors, or with the empty vector (pcDNA3). This method allows a long lasting expression of circulating IFN [8]. Mx1 immunodetection was used to identify IFN-λ responding cells. IFN-λ-responing cells were identified in Mx-IFNAR10/0 mice electroinjected with the IFN-λ expressing plasmid, whereas IFN-α-responsive cells were identified in Mx-IFNLR10/0 mice electroinjected with the IFN-α-expressing plasmid. Mx-IFNAR10/0 IFNLR10/0 mice served as negative controls. We observed a response to IFN-λ in cytokeratin-positive cholangiocytes, but not in hepatocytes (Fig. 1A). The response to IFN-λ differed strikingly from the response to IFN-α. Many interstitial cells as well as endothelial cells responded to IFN-α. Surprisingly, however, no IFN-α response was observed in hepatocytes (Fig. 1B). As expected, the liver of Mx-IFNAR10/0 mice responded neither to IFN-α nor to IFN-λ, although very few unidentified interstitial cells appeared to constitutively express Mx1 (data not shown).

It was reported that prolonged stimulation of liver cells with IFN-α triggers desensitization of the IFN response pathway [25]. Such refractoriness was not observed, however, in the case of IFN-λ [26]. To rule out that the lack of Mx1 expression in mouse hepatocytes was related to IFN refractoriness, we monitored Mx1 expression in the liver of mice subcutaneously injected with a single dose of recombinant IFN-α or IFN-λ (Fig. 1C). In this case, Mx1 expression could be readily detected in hepatocytes of Mx-IFNLR10/0 mice treated with IFN-α. However, as in the previous experiment, no Mx1 expression was detected in hepatocytes of Mx-IFNAR10/0 mice treated with IFN-λ.

Hepatocytes do not Respond to IFN-λ, in Livers Infected with a Hepatotropic Strain of Influenza A Virus
The apparent absence of IFN response in hepatocytes observed in the previous experiment was unexpected. It might be explained by low-level supply of IFN from the bloodstream after plasmid electroinjection-based expression in mice. This artificial system might not mimic the local high concentrations of IFN which are probably reached in virus-infected tissues. To test whether hepatocytes can respond to IFN-λ, we infected local concentrations of IFN, Mx-IFNLR10/0 and Mx-IFNAR10/0 mice were infected for 24 (not shown) and 48 hours, respectively, with mouse hepatotropic influenza A virus strain TURH. RT-qPCR and immunohistochemistry confirmed the infection of livers and lungs (Fig. 2A–C). Livers and lungs of Mx-IFNAR10/0 mice were much more strongly infected than those of Mx-IFNLR10/0 mice, in agreement with the previous report showing stronger influence of type-I IFN on influenza A virus infection [13]. Both in the liver and in the lung, Oasl2 mRNA expression was strongly induced in IFNAR10/0 mice (Fig. 2D–E), suggesting that these tissues readily responded to IFN-λ produced in response to infection. IFN was produced locally in response to viral infection, as transcription of both IFN-β and IFN-λ genes was strongly upregulated in the livers of infected Mx-IFNAR10/0 mice (Fig. 2F–G).

To study the IFN response in hepatocytes, we performed Mx1 immunolabelings on liver sections from mice infected for 48 hours (Fig. 3). In infected Mx-IFNLR10/0 mice, many scattered Mx1-positive hepatocytes were detected in the liver (Fig. 3A), with the response being most intense close to infection foci, confirming the ability of hepatocytes to respond to type I IFN. In contrast, no response to type III IFN was detected in hepatocytes of Mx-IFNAR10/0 mice. In livers of these mice, the only cells responding to type III IFN were the cholangiocytes, as previously observed with electroinjected animals (Fig. 3B). Thus, in spite of massive local IFN production, hepatocytes did not respond to type III IFN, while they responded to type I IFN.

Human but not Mouse Hepatocytes Respond to IFN-λ
The data presented above, as well as previously published works show that, unlike human hepatocytes [9,11], mouse hepatocytes do not respond to IFN-λ [8,13]. This raised the question of whether the lack of responsiveness of mouse hepatocytes to IFN-λ was due to the nature of the hepatocytes, or to the microenvironment in mouse livers. To answer this question we used Alb-uPA-SCID transgenic mice, which were engrafted with human
hepatocytes. These mice have chimeric livers containing both mouse and human hepatocytes [10,27,28]. Chimeric mice were electroinjected either with a plasmid expressing human IFN-λ3, or a mix of plasmids expressing human and mouse IFN-α, or with the empty vector (pCDNA3). The antiviral activity of type I IFN is species-specific [29,30]. Therefore, in order to monitor the IFN-α response in chimeric livers, a 50:50 mixture of plasmids expressing human IFNα2 and mouse IFN-α2 was used for electroinjection. In contrast, mouse cells can respond to human IFN-λ and vice versa (Fig. S1). Therefore, we used a single plasmid expressing hIFN-λ3 for electroinjection. At 7 days post-electrotransfer, ISG expression was measured in the kidneys and livers, using RT-qPCR, to evaluate the overall IFN response (Fig. 4A-B). The response of mouse cells was quantified by measuring expression of mouse Oasl2. The response of human hepatocytes was quantified by measuring expression of human OAS1 and MX1. In IFN-α-expressing mice, we observed a significant increase of mouse Oasl2 transcripts in chimeric livers (p = 0.05). As in previous experiments, no significant mouse Oasl2 response to IFN-λ was detected in livers (p = 0.2), while a clear response to this cytokine was observed in kidneys (p = 0.05) (Fig. 4A). Importantly, we observed very good human OAS1 and MX1 responses to IFN-λ in chimeric livers (p = 0.05) (Fig. 4B).

The prominent IFN-λ response of human hepatocytes was further visualized by immunohistofluorescence analysis of liver sections. Human hepatocytes were identified using anti-human cytokeratin 18 (Fig. 4C) or anti-human albumin antibodies (Fig. S2). In chimeric mice treated with either IFN-λ or IFN-α, most human hepatocytes were strongly positive for MxA. Taken together, these results show that human hepatocytes in a mouse environment are able to respond to type III IFN.

Discussion

In this work, we highlight the lack of responsiveness of mouse hepatocytes to IFN-λ in vivo. Even when high amounts of IFN-λ were produced locally after influenza A virus infection, the IFN-λ response was confined to cholangiocytes. Previous works showed that mouse livers responded poorly to IFN-λ [8,13]. However, using RT-qPCR and Northern blot analysis a recent study showed that primary mouse hepatocytes can respond to IFN-λ [9]. Nonetheless, since these results were obtained in vitro, it remains possible that the hepatocytes did not behave exactly as they would in vivo. Here, we analyzed the IFN-λ response, at the cellular level, in the intact mouse liver. We show that cholangiocytes were the predominant cells responding to IFN-λ in mouse liver. No response to IFN-λ was observed in hepatocytes, even in infected livers where high amounts of IFN were expected to be produced locally.

Human hepatocytes, however, were shown to be responsive to IFN-λ in vitro [9,11]. In vivo, good antiviral activity was observed against HCV with PEG-IFN-λ [12]. Clinical studies are currently ongoing for the use of IFN-λ in the treatment of viral diseases in human.

However, to our knowledge, a formal proof that hepatocytes directly respond to IFN-λ is still lacking. The most compelling evidences that IFN-λ acts on human hepatocytes are the detection of IFNLR1 by immunohistochemistry on hepatocytes in sections of hepatic biopsies [11], and the relatively high expression level of IFNLRI mRNA in human hepatocytes engrafed in mice with chimeric livers [31].

Using Alb-uPA-SCID mice with chimeric livers we demonstrated that human hepatocytes present in a mouse environment can respond to circulating IFN-λ. This result does not unequivocally prove that human hepatocytes are physiologically responsive to IFN-λ. Indeed, although these hepatocytes were not cultured in vitro, one cannot completely rule out the fact that IFNLRI expression was consequent to the hepatocyte isolation procedure. Yet, it is very likely that human hepatocytes do respond to IFN-λ and we postulate that epigenetic factors might silence IFN-λ receptor expression in mouse but not human hepatocytes.

Our results further show that the lack of responsiveness of mouse hepatocytes to IFN-λ is not due to the murine environment since human hepatocytes present in the same tissue readily responded to IFN-λ.

In conclusion, our data suggest that human but not mouse hepatocytes are responsive to IFN-λ. This highlights the existence of some limits to the use of mouse models in the study of human hepatotropic pathogens.

Fluorescence microscopy images showing co-immunostainings of human MxA and human albumin in liver sections of Alb-uPA-SCID transgenic mice electroinjected with IFN-α or IFN-λ expression plasmids or with the empty plasmid (mock). Hoechst: nuclear staining. Results are representative of two independent experiments. (TIF)

Materials and Methods S1 This section describes the cells [33,34] and procedures used to produce and quantify IFNs. (DOCX)

Acknowledgments

We are grateful to Muriel Minet and Lieve Verhoey for expert technical assistance. We thank S. Kotenko (New Jersey Medical School, Newark, NJ, USA) for the gift of IFN-λ-expressing plasmids. We also thank F. Lemaigre (de Duve Institute, Univ. of Louvain, Belgium) and Isabelle Leclercq (Institute of experimental and clinical research, IREC, Univ. of Louvain, Belgium) for the gift of antibodies and advices in the detection of hepatocytes by immunohistochemistry.

Author Contributions

Conceived and designed the experiments: PH CD T. Mahlakoiv PS PM T. Michiels. Performed the experiments: PH CD T. Mahlakoiv PS PM T. Michiels. Analyzed the data: PH CD T. Mahlakoiv PS PM T. Michiels. Wrote the paper: PH CD T. Mahlakoiv PS PM T. Michiels.
