Abstract

**Background:** Interleukin-4 (IL-4), as the most prominent anti-inflammatory cytokine, plays an important role in modulating microglial activation and inflammatory responses in Alzheimer’s disease (AD), a chronic inflammatory disorder.

**Objectives:** The current study aimed to develop a new recombinant Adeno-associated viral (rAAV) vector that delivers IL-4 and then assess the counterbalancing effect of the new construct along with recombinant IL-4 (rIL-4) protein in in-vitro models of AD.

**Materials and Methods:** The rAAV-IL4 was originally prepared and then employed along with rIL-4 protein to counter Amyloid β (1-42)-induced proinflammatory cytokines in a primary microglia cell culture and the B92 rat microglia continuous cell line, using relative Real-Time PCR assay.

**Results:** Aβ (1-42) stimulated the production of the proinflammatory cytokines IL6, IL1β, TNFα, and IL18 in both the primary microglia cell culture and the B92 cell line. Both the rAAV-IL4 construct and the rIL-4 protein were found to inhibit production of the most important Aβ (1-42)-induced proinflammatory cytokine mRNAs in the two types of cells with different patterns.

**Conclusions:** It seems that the new construct can serve as an appropriate option in the modulation of Aβ-induced proinflammatory cytokine gene expression and microglia activation in patients affected by AD.

**Keywords:** Alzheimer Disease, Adeno-Associated Viral Vector, Amyloid β (1-42), Proinflammatory Cytokines, IL-4, Primary Microglia Cell, B-92 Cell Line

1. Background

Recombinant Adeno-associated viral (rAAV) vector is one of the most desirable vehicles for gene delivery to the central nervous system (CNS), post-mitotic tissues, and in immune-privileged situations (1).

Adeno-associated virus is a small DNA virus having a 4.7 kb genome and belonging to the Parvoviridae family, the Parvovirinae subfamily, and the Dependovirus genus. Currently, more than 100 isolates of AAV species from various animals have been identified (2). Diverse tissue tropism; very mild immune reaction; no relation to any well-known disease; genome integration; and long-term, stable gene expression make this virus an appropriate vector to deliver trans-complementary genes to various problematic organs and tissues such as muscle, liver, eye, and CNS (2,3). Recently, AAV viral vector has been used to investigate various neurological disorders such as Alzheimer’s disease (AD) (4,5), Parkinson’s disease (PD) (6), and spinal cord injury (7).

Alzheimer’s disease is the most frequent cause of dementia in the aging population. It is expected that the number of those with AD will increase by approximately 50% by 2050 (8,9). Brain atrophy and neuronal-cell loss are the main hallmarks of this disease (10,11) and are associated with two significant neuropathological features: neurofibrillary tangles (NFTs) and neuritic plaques (10). Neurofibrillary tangles are inter-neuronal, dense bundles of hyper-phosphorylated tau protein, and neuritic plaques are intra-neuronal masses surrounding a fibrillar β-amyloid core. Activated microglia are consistently associated with these plaques, and it is believed they are stimulated by Amyloid-β (Aβ). Amyloid-β fragments serve as immunoglobulin (Ig) and activate inflammatory mechanisms via alternative pathways, while the classic inflammatory response is absent (12).

The activation of microglia associated with neuritic plaques leads to the production of proinflammatory cytokines, inflammatory markers, and neurotoxic mediators, including MHC-I and II, TNF-α, IL-6, IL-1β, B7-I,
B7-2, IFN-α, GMCSF, type B of IL-8 receptor, MCP-4, iNOS, NO, CD40, and others (10, 13-15).

Given the established evidence demonstrating the role of the inflammatory process in AD pathogenesis, researchers are investigating the use of anti-inflammatory drugs as a treatment option for the disorder (5, 16). IL-4, the most popular anti-inflammatory cytokine, has a significant inhibitory role in the expression and release of the proinflammatory markers, including IL-1, IL-6, IL-8, and TNF-α, and stimulates the synthesis of IL-1 receptor antagonist (IL-1ra), which blocks the action of IL-1α and IL-1β (17-20). In addition, IL-4 expression results in marked expression of the scavenger receptor CD36, the Amyloid-β degradation enzyme neprilysin (NEP), and insulin-degrading enzyme (IDE) (19).

2. Objectives

The present study aims to construct a unique rAAV vector that expresses IL-4, which counters AD and its deleterious immune reactivated pathways. For this purpose, we generate high-transduction efficiency rAAV that encodes IL-4 and model its effect for the first time in vitro, evaluating its inhibitory effects on the inflammatory process induced by Aβ (1-42) in primary and continuous cell lines using real-time PCR assay.

3. Materials and Methods

3.1. RNA Extraction, cDNA Synthesis, and Cloning of the PCR Product

Adult male Sprague Dawley rats weighing 175 - 200 g were procured from Shiraz University of Medical Sciences Animal Center and housed in the Animal House of Nemazi Hospital, Shiraz, Iran. The tail artery was cut to drain the oxalate blood. Total RNA was isolated from fresh peripheral blood mononuclear cells (PBMCs) with the use of QIAamp RNA blood mini kits (QIAGEN; Valencia, CA), according to the instructions provided by the manufacturer. Appropriate primers for the IL-4 gene were designed based on the published RNA sequences. The rat IL-4 primer sequences were as follows: IL-4 upstream: 5’- CGCGGATCCCTGACTGTAGAGAG-3’ and IL-4 downstream: 5’- CCCCAGATCCTCTCGTAGAGAG-3’. The expected length of the PCR products was 444 bp.

The RNA was reverse-transcribed and amplified by PCR with a one-step RT-PCR assay in a total volume of 50 µL with 0.2 mg of total RNA and 1 mM each of upstream- and downstream-specific primer corresponding to the interested sequences. Reactions were incubated at 48°C for 45 minutes, heated to 94°C for 2 minutes, and cycled according to the following parameters: 94°C for 30 seconds, 52°C for 1 minute, and 72°C for 2 minutes for a total of 40 cycles. After 40 cycles, a 20-minute final extension at 72°C was performed.

The cloning of the IL-4 cDNA into pTZ57R/T was performed as described by the supplier (InstaClone PCR cloning kit; Fermentas; USA). Then, it was transformed into the Escherichia coli DH5α. The transformants were chosen on LB-Amp (50 mg/mL) agar plates supplemented with IPTG and X-Gal. Desired constructs were confirmed by PCR, restriction enzyme analysis, and, finally, DNA sequencing (MWG Co; Germany) using universal M13 PUC primers.

3.2. Generation, Purification, and Quantification of rAAV-IL4 Gene Expression

The pTZ57R/T-IL4 was digested with BamHI/EcoRI and subcloned into corresponding restriction sites of pAAV-IRES-Hygro (CMV promoter; Cell Biolab; San Diego, CA). To prepare the rAAV-IL4, the desired construct (pAAV-IRES-Hygro-IL4) was cotransfected with the pAAV-DJ/8 Vector (containing AAV-2 Rep, AAV-DJ/8 Cap, and ampicillin resistance genes) and Helper Vector (containing Adeno E2A, Adeno E4, and Adeno VA) into the AAV-293 cell line, using Lipofectamine 2000. The rAAV-IL4 vector was purified using ViraBin AAV purification kits (Cell Biolab; San Diego, CA). The genome copy number was assessed by QuickTiter AAV quantitation kits (Cell Biolab; San Diego, CA).

3.3. Primary Microglia and the B92 Cell Culture

Primary cultures of microglia were provided from Wistar rat pups 1 - 2 days old. Briefly, in aseptic conditions, the skull (without any brain squish) was removed and 3 layers of meninges were stripped from the cortices in a sterile Petri dish containing pre-chilled Hank’s buffer salt solution (HBSS). Dissected cortex tissue was transferred into 50 mL of sterile, ice-cold, conical tubes containing 10 mL of dissociation media (CaCl2 and MgCl2 - free MEM + penstrep + 0.25% trypsin-EDTA) on ice. Maintaining the cold-chain condition, cultured media was replaced with 12 mL of dissociation media as often as possible, and the cortex was then gently pulverized and homogenized 10 - 15 times using a fire-polished 10-mL glass, Pasteur pipette and, finally, stirred for 10 minutes at 37°C in the laminar-flow hood. Once the homogenized suspension reached 50 mL, high glucose DMEM + 10%, inactivated FBS + penstrep was added and centrifuged 1000 × g for 10 minutes. The cells were re-suspended in growth medium, followed by seeding of 1.5 × 10^6 cells in 25 cm² flasks coated with poly-l-lysine and grown at 37°C in a 95% humidified, 5% CO2 cell-culture incubator. Growth medium was replaced 7 days after mixed-
glial cell culture occurred. Approximately 2 weeks after initial plating, when astrocytes reached 100% confluence, microglia, growing as a small, rounded cell on the top layer, was detached from the astrocytes bed by gentle shaking, and then, $2 \times 10^5$ viable cells/well were reseeded in 24-well culture plates.

The B92 cells were prepared from the Pasteur Institute of Iran and maintained in DMEM + 10% FBS + penstrep at 37°C in a 95% humidified, 5% CO₂ cell-culture incubator, and $3 \times 10^5$ cells were plated in 24-well culture plates.

3.4. Treatment of Primary Microglia and B92 Cells With $\text{A}\beta$ in the Presence or Absence of rAAV-IL4 and rIL-4 Protein

In the first experiment, to evaluate $\text{A}\beta$ (1-42)-induced proinflammatory cytokine expression patterns, one 8-series of $3 \times 10^5$ of B92 cells and $2 \times 10^5$ of primary microglia cells were grown in a 500-l medium containing 10% FBS in 24-well plate tissue-culture plates for 24 hours. After incubation overnight, cells were incubated with 500 l of 10% FBS growth media containing 10 µM of $\text{A}\beta$ (1-42) for 0, 1, 2, 4, 8, 16, 24, and 48 hours.

In another experiment to assess the counterbalancing effect of IL-4 against $\text{A}\beta$ (1-42)-induced proinflammatory cytokines, both B92 cells and primary microglia cells were grown, following the same method as used in the above experiment, for 24 hours. The following morning, the medium was replaced with 200 l of fresh medium containing 10% FBS and 150 l of culture medium containing 10 nM of recombinant rat IL-4 protein or 1010 pfu of rAAV-rat-IL4 construct. Both were incubated for 1 hour, and then 150 l of culture medium containing 34 µM of $\text{A}\beta$ (1-42) was added to the plates and incubated for 0, 1, 2, 4, 8, 16, 24, and 48 hours.

3.5. Real-time Quantitative PCR to Detect Changing of Cytokine Gene Expression

In both series of the above experiments, the proinflammatory mRNA expression levels were quantified using the SYBR green PCR assay system. The reaction mixtures (20 l) consisted of 1X power SYBR green PCR master mix buffer (Applied Biosystems; UK), 400 nM of each primer, and 200 ng of cDNA. Table 1 shows the primer sequences of the desired proinflammatory cytokines. The reaction conditions were an initial 2 minutes at 50°C and 10 minutes at 95°C, followed by 40 cycles of 15 sec at 95°C and 30 seconds at 65°C.

3.6. Statistical Analysis

The results were analyzed by SPSS for windows systems (Version 16.0, 2007; SPSS Inc; Chicago, IL). A two-sided Student’s t test was applied to analyze the RT PCR results. Values were considered significant when $P < 0.05$. The results were expressed as mean ± SEM.

4. Results

4.1. Preparation of the rat rAAV-IL4

The total PBMCs RNAs of the rats were extracted, and 444 bp of IL-4 cDNA was synthesized. The desired gene was amplified using specific primers and then evaluated through electrophoresis on 2% gel agarose Figure 1. The IL-4 cDNA was cloned in pTZ57R/T cloning vector and then evaluated by restriction-enzyme analysis and sequencing (Figure 2). The EcoRI/BamHI digested construct was subcloned into the corresponding restriction site of the AAV plasmid. The presence of a desired gene was confirmed by restriction-enzyme analysis.

4.2. mRNAs’ Proinflammatory Cytokine Patterns Induced by $\text{A}\beta$ (1-42)

The current study investigated the mRNA expression level of the specified proinflammatory cytokines, IL1-β, IL-6, TNF-α, and IL-18, in $\text{A}\beta$ (1-42)-induced rat primary microglia cell culture and the B92 cell line over a 48 hours period.

In the primary microglia cell culture, the greatest fold changes occurred in the expression of IL1-β, TNF-α, IL-6,
Table 1. Sequences of Forward and Reverse Primers for Quantitative PCR

| Primer Name | Forward Primers | Reverse Primers |
|-------------|-----------------|-----------------|
| rat IL-6    | 5’CGAGCCCACCAGGAACGAAAGTC3’ | 5’CTGGCTGGAAGTCTCTTGCGGAG3’ |

Abbreviations: AD, Alzheimer’s disease; IL-4, Interleukine-4; IL-18, Interleukine-18; IL-1β, interleukine-1β; IL-6, interleukine-6; TNF-alpha, tumor necrosis factor-alpha.

and IL-18 mRNAs sequentially, while the primary raised cytokine was TNF-α within 4 hours after Aβ(1-42) treatment (Figure 3A). In the B92 cells, TNF-α increased remarkably, followed by IL-1β, IL-6, and IL-18 (Figure 3B). It is notable that the expression level of proinflammatory cytokines in microglia primary cell cultures was generally higher than in the B92 cell line.

4.3. Inhibitory Effect of rIL-4 and rAAV-IL4 on Proinflammatory Cytokine Production in the B92 Cell Line and the Primary Microglia Cell Culture

The present study surveyed the modulatory effects of both recombinant IL-4 protein and rAAV that expressed IL-4 on the production of the selected proinflammatory cytokines in both primary microglia and the B92 cell line. Recombinant IL-4 protein down-regulated the expression of Aβ-induced IL-1β, IL-6, TNF-α, and IL-18 mRNAs in both cell types, although the TNF-α changes were slight (Figure 4).

Since the AAV vector used in this study has a relatively high transfection capability in vitro compared to other naive AAV vectors, rAAV-IL4 can inhibit the production of the above proinflammatory cytokines in both primary microglia cell culture and the B92 cells, except TNF-α and IL-1 mRNA expression, and especially in those B92 cells that were slightly attenuated.

5. Discussion

Various studies have shown the detrimental effects on AD patients’ CNS of proinflammatory cytokines, which are predominantly elicited from microglial cells with chronic exposure to Aβ. The injurious effects of proinflammatory cytokines can lead to neuronal dysfunction and death through mechanisms including the induction of nitric oxide (NO) production (21, 22); long-term potentiation (LTP) of synaptic transmission inhibition, which plays a key role in the formation of memory (23, 24); and reduced hippocampal neurogenesis (25).

Immunotherapy is a newly developed strategy that can help to slow cognitive impairment and reduce the AD-associated lesions (26). Since anti-inflammatory cytokines can protect the CNS from lesions caused by proinflammatory cytokines (27-29), IL-4, as the most prominent anti-inflammatory cytokine, has a wide range of implications for treating AD (4, 26, 27, 30, 31). This cytokine can polarize T-cells and macrophages to Type 2 morphology (Th2 and M2) and accelerate amyloidosis (32). Kiyota et al. showed that AAV-mediated IL-4 can reduce the burden of Aβ(1-42) in vivo (4). Zhao et al. demonstrated that IL-4 can protect the microglia by inhibiting production of free radicals (33). In addition, several other mechanisms of the inhibitory effects of IL-4 have been noted, including its inhibition of formyl peptide receptor (FPR) (34).

This study established that AAV encoding IL-4 the same as rIL-4 protein against Aβ(1-42)-induced IL1β, IL-6, TNF-α, and IL-18 proinflammatory cytokines in rat primary microglia and in the B92 rat microglia cell line (28). The AAV vector used has a complex library of hybrid capsids from eight different wild-type viruses and has high transduction efficacies, especially in vitro, compared to other wild type serotypes.

Several studies have shown an elevated level of TNF-α in the serum and cerebrospinal fluid (CSF) of AD patients and have confirmed the potential involvement of this prominent proinflammatory cytokine in AD pathology (31, 35). Tobinick et al. demonstrated that consumption of a TNF-α inhibitor (Etanercept) by AD patients leads to a significant improvement (38). Szczepanik et al. (28) reported that TNF-α was secreted from Aβ(1-42)-induced primary microglia and the THP-1 cell line (39). The current study used quantitative PCR assay to confirm acceleration of the mRNA level of TNF-α in Aβ(1-42)-induced primary and con-
Elevated levels of IL-6 (40, 41) and its contribution to pathophysiology in AD patients has been shown by Cojocaru et al. (41). As shown in Figure 3, the mRNA of this cytokine increased markedly against Aβ (1-42) induction. Bossu et al. (42) demonstrated an increased IL-18 cytokine level in AD patients and a positive correlation between IL-18 expression and AD-related cognitive impairment (43, 44). The present study demonstrated that Aβ (1-42), like other assessed proinflammatory cytokines (45), can induce IL18 mRNA expression, while its expression can be inhibited by the anti-inflammatory cytokines, either rIL-4 or rAAV-IL4.

In AD-affected patients, the expression of Aβ (1-42)-induced proinflammatory cytokines can cause progressive dementia because of negative neurodegenerative effects. IL-4 not only protects neurons from further injury, but also revives the impaired neurodegenerative lesions (46) by inhibiting IFN-λ priming of microglia through cAMP signaling, with later reduction in impairing proinflammatory cytokines such as TNF-α, IL-1β, and nitric oxide (47).

In conclusion, this study has shown that anti-inflammatory gene delivery by AAV vector plays a significant role in modulating immune response in Aβ (1-42)-induced processes. In addition, it seems that this newly suggested treatment could have implications in other allergic disorders, autoimmune diseases, and
transplant rejection.

Acknowledgments

Our special thanks go to Dr. MR Namavar, whose help with manipulation and isolation of rat microglia cells is highly appreciated. We also thank Dr. Hassan Khajehei for copy editing the manuscript.
