By analyzing a unique dataset of more than 270,000 scientists, we discovered substantial gender differences in scientific collaborations. While men are more likely to collaborate with other men, women are more egalitarian. This is consistently observed over all fields and regardless of the number of collaborators a scientist has. The only exception is observed in the field of engineering, where this gender bias disappears with increasing number of collaborators. We also found that the distribution of the number of collaborators follows a truncated power law with a cut-off that is gender dependent and related to the gender differences in the number of published papers. Considering interdisciplinary research, our analysis shows that men and women behave similarly across fields, except in the case of natural sciences, where women with many collaborators are more likely to have collaborators from other fields.

INTRODUCTION

The challenges faced by women in academia are considered to be responsible for their ubiquitous underrepresentation [1–4]. Signs of gender asymmetries are reported in several academic related activities such as hiring [5], grant funding [6], collaboration strategies [7], and even in the ordering of the list of authors in papers [8]. These studies are usually based on indirect analysis of scientific productivity [9] and the evaluation of their career strategy [4, 7, 10]. Here, we address the question of gender asymmetry from a different perspective. Many successful and high-impact research works result from the combination of skills, methods, and ideas of distinct team members. Thus the mechanisms of team building strongly affect the collaboration network structure and, consequently, its performance [11]. It is under this framework that we analyze a dataset with more than 270,000 scientists in Brazil and find that men are more likely to collaborate with other men than one would expect from the gender distribution across fields. By contrast, for women no significant gender bias is observed.

In order to apply for grants and fellowships at any career level, scientists in Brazil are required to register in the Lattes Platform [12]. This results in a very detailed public database, which includes all active scientists in Brazil and their full list of scientific publications. In contrast with other databases, in this platform, articles are uniquely identified by their DOI and possible ambiguities related to author names are practically solved [13, 14]. Besides, it also includes personal information such as gender, research field, and actual and previous academic positions. As a consequence, the application of network science methods [15–18] to the collaboration network can provide quantitative information for future discussions on the mechanisms responsible for the observed gender disparities [19].

The manuscript is organized as follows. In the next section, we present the results for the distribution of the number of collaborators, gender differences, and degree of research interdisciplinarity. Final conclusions and details about the methods are discussed afterwards.

RESULTS

The number of collaborators a scientist has is a cumulative quantity that depends on the entire scientific career. As shown in Fig. 1a, the resulting distributions for men and women are consistent with a truncated power law, $P = Ak^{-\alpha}e^{-k/\beta}$, with the same exponent $\alpha = 1.53$ for both genders. However, the value of the parameter $\beta$ for men is almost twice the one obtained for women, namely, 85.4 and 49.5, respectively. This difference reflects the tendency for men to have more collaborators than women.

In order to distinguish circumstantial from recurrent collaborations, we define the weight $w$ of a collaboration between a pair of authors as the total number of papers co-authored by them. Figure 1b shows the distribution of weights for both genders. The list-squares fit of the data to a power law, $P(w) = Bw^{-\lambda}$, gives $\lambda = 3.17 \pm 0.06$ and $\lambda = 2.68 \pm 0.04$, for men and women, respectively. This difference in $\lambda$ might be related to the difference in the number of collaborators and papers. Table I summarizes the average number of collaborators and papers split...
by gender and research field. On average, men produce more papers and have more collaborators than women even in the fields where women are traditionally highly represented. An exception is the average number of collaborators in Linguistics and Arts, which is very similar for both genders.

To evaluate homophily in the collaboration network,

we define the gender ratio of a scientist \(i\), \(g\)-ratio\(_i\), as

\[
g\text{-ratio}_i = \frac{\sum_j w_{ij}}{\sum_j w_{ij}} \tag{1}
\]

where the sum in the denominator is over all collaborations, while the one in the numerator is only over collaborations with women, and \(w_{ij}\) is the weight of the collaboration between scientist \(i\) and \(j\). Figure 2 depicts the average \(g\)-ratio for men and women across eight dif-

![FIG. 1. a) Distribution of the number of collaborators for men (blue squares) and women (red asterisks). The distributions are fitted with a truncated power law, \(P(k) = Ak^{-\alpha}e^{-k/\beta}\), plotted as dashed lines with colors corresponding to data points. The best fit is obtained for \(\alpha = 1.53\), and \(\beta = 85.4\) and \(\beta = 49.5\), for men and women, respectively. b) Distribution of the number of recurrent collaborations between scientists (weights) for men (blue squares) and women (red asterisks). Solid lines are power-law fits, \(P(w) = Bw^{-\lambda}\), with colors corresponding to data points. For men, \(\lambda = 2.68 \pm 0.04\), while for women \(\lambda = 3.17 \pm 0.06\).](image)

For Engineering, the \(g\)-ratio is even above the fraction of women in the field. Error bars indicate the standard error for each bin.](image)
different fields. On average, women display a higher \textit{g-ratio}, regardless of the field, and always close to the fraction of women working in the respective field. Men have relatively more collaborations with other men, indicating a tendency to a homophilic pattern. Previous results based on a rather small number of scientists suggested that women collaborate more with other women [10, 20], but we show that this is not the case for this much larger dataset.

The evidence of gender asymmetries raises the question of how it depends on the number of collaborators \( k \). Except for \textit{Engineering} (see inset in Fig. 3), the \textit{g-ratio} does not depend strongly on \( k \). The values for women are always closer to the fraction of women in the respective field and the values for men are always consistently lower. This is exemplarily shown for \textit{Biological Sciences} in Fig. 3. For \textit{Engineering}, collaboration with women grows continuously with \( k \) and even beyond the fraction of female scientists for men and women with more collaborators (see inset).

It has been reported that women are more involved in interdisciplinary research than their male peers [15]. To evaluate this tendency in our dataset, we define the interdisciplinary ratio \( m\text{-ratio}_i \), as,

\[
m\text{-ratio}_i = \frac{\sum_j w_{ij}}{\sum_j w_{ij}}
\]

where the sum in the denominator is over all collaborators, while the one in the numerator is only over collaborators in a different field. The results are summarized in Table II. We observe that women have more interdisciplinary collaborations than men for six fields, the exceptions being the fields of \textit{Humanities} and \textit{Linguistics and Arts}. The largest discrepancy is observed for \textit{Exact and Earth Sciences}. Nonetheless, the differences are consistently smaller than the ones found for the \textit{g-ratio}. When analyzing the dependence on the number of collaborators, we observe the same tendency for men and women, as shown in Fig. 4. However, for \textit{Exact and Earth Sciences}, women with a larger number of collaborators (more than 100) are considerably more engaged in interdisciplinary research than men, with similar number of collaborators (see inset).

| ENG   | 0.331 ± 0.005 | 0.254 ± 0.003 |
| LIN   | 0.274 ± 0.007 | 0.303 ± 0.011 |

**CONCLUSION**

We have found gender differences regarding scientific collaborations in the Lattes Platform, a large dataset comprising more than 270,000 scientists. The number of collaborators and the weight of collaborations, measured in terms of the number of common publications, are both heavy tailed for men and women. Two metrics were introduced to investigate gender differences, namely, the \textit{g-ratio}, that measures the fraction of collaborations with women, and the \textit{m-ratio}, measuring the fraction of interdisciplinary collaborations.

With the \textit{g-ratio}, we found that men collaborate more with other men than with women, and this happens systematically across different fields and regardless of their number of collaborators. The \textit{m-ratio} analysis reveals that men and women have the same tendency to participate in interdisciplinary research, with women being slightly more engaged. For \textit{Exact and Earth Sciences}, women with a larger number of collaborators are considerably more likely to work with scientists of a different field.

The path to gender balance in academia must involve not only government and institutional support, but also consciousness of the asymmetries in the current collaboration network. Our results are expected to provide quantitative support to future analyses and discussions.
The specific causes for the homophilic pattern should also be investigated.

METHODS

For analyzing the collaboration patterns in Lattes Platform, the XHTML source code from circa 2.7 million curricula were extracted from the website [12] in June 2012. A parser was developed to extract information from the downloaded information.

When filling their curricula, scientists may choose up to three research fields. These are research topics organized in a hierarchical tree-like structure comprising eight major fields: Agricultural Sciences (AGR), Applied Social Sciences (SOC), Biological Sciences (BIO), Exact and Earth Sciences (EXA), Humanities (HUM), Health Sciences (HEA), Engineering (ENG) and Linguistics and Arts (LIN). Each of these have their own subfields. When assigning a specific field to a scientist, we considered the first displayed major field.

The procedure adopted to identify the collaborations is based on previous studies of the Lattes Platform [21]. A list, containing title, year of publication and number of authors of each paper published is created. More than 3.5 million papers are present in this list. The collaborations are identified by looking for duplicate records in the list. Due to typographical errors [22], an exact string matching would fail to identify collaborations. The Demearau-Levenshstein approximate string matching algorithm [23] is therefore used to define a distance between paper titles. Papers distant by less than 10% of the maximum distance, with the same number of authors and published in the same year are considered to be the same. Due to the extensive number of records, only papers published in the same year, with the same number of authors and starting with the same letter are compared. Following this procedure, more than 620 thousand collaborations were identified.

With a list of duplicate papers, a bipartite network BN is constructed containing two vertex classes, scientists (R) and papers (P). In this work, we analyze the projection of BN onto R, which we call TCN (Total Collaboration Network). Two scientists are said to collaborate if they are connected to a same paper in BN. The weight wij of their collaboration is defined as the number of papers in BN which both are connected to. We note that these networks are cumulative, with publications date spanning more than five decades. 11.5% of the scientists in TCN do not include field information on their curricula. The proportions of female scientists varies across fields [8] and the values for TCN are shown in Table III.

Previous works on gender and collaboration [7, 10, 15, 20, 24] had information from a much smaller number of authors, usually much less than 10,000. Here, we have information concerning the productivity (as measured by article output) of 275,061 scientists with published papers on periodicals, 130,525 men (47.4%) and 144,440 women (52.5%). Only 96 scientists do not display the gender information on the curriculum. 90.4% belong to the giant component of the TCN.
