Reaction of 2,2,4,4-tetrakis(trifluoromethyl)-1,3-dithiethane with N-vinyl compounds

Viacheslav A. Petrov*1,§ and Will Marshall2

Abstract

The reaction of hexafluorothioacetone dimer (2,2,4,4-tetrakis(trifluoromethyl)-1,3-dithiethane, 1) with vinylamides leads to the rapid formation of [2 + 2] cycloadducts: 4-amino-2,2-bis(trifluoromethyl)thietanes. The reaction proceeds in polar solvents (DMF, DMSO) in the absence of a catalyst at elevated temperature producing the corresponding cycloadducts in 47–86% yield. The reaction of N-vinylimidazole unexpectedly led to the formation of the corresponding 1-(hexafluoroisopropyl)-3-vinyl-1,3-dihydro-2H-imidazole-2-thione (5). The structure of this compound, along with the structures of two new thietanes was confirmed by single crystal X-ray diffraction.

Introduction

Hexafluorothioacetone (HFTA) and hexafluorothioacetone dimer (2,2,4,4-tetrakis(trifluoromethyl)-1,3-dithiethane (I) were shown to react with a wide variety of electron-rich olefins and dienes, producing the corresponding cycloadducts. Reported examples include the corresponding thietanes, derived from the reaction of HFTA with vinyl ethers, vinyl sulfides, cyclic dienes and styrenes [1,2], fluoride anion-catalyzed reactions of compound 1 with vinyl ethers [1,3,4], vinyl sulfides [3], ketene dimethylacetal [5], styrenes [6,7], cyclic dienes [8] and quadracyclane [9]. At this point, no data for the reaction of HFTA or HFTA dimer with vinylamines can be found in the literature, despite the fact that (CF3)2C≡C=S (which exhibits a reactivity very similar to the reactivity of HFTA) was reported to react with N-vinylcarbazole to give a [2 + 2] cycloadduct [10]. In this paper we report the synthesis of 2,2-bis(trifluoromethyl)-4-amino-substituted thietanes by a reaction of 1 with selected vinylated amino compounds.

Results and Discussion

It was found that N-vinylamides 2a,b react with 1 in the absence of a catalyst in polar solvents to produce the corresponding thietanes 3a,b in moderate yield (Scheme 1). The reaction can be carried out at either ambient or elevated temperature (see Table 1).
Table 1: Reaction conditions, yields, melting/boiling points and MS data for compounds 3a–e and 5.

| Compound | Methoda | Temp. (°C)/Time (h), Solvent | Yield (%) | Mp (°C), (bp °C/mmHg) | MS (m/z) |
|----------|---------|-----------------------------|-----------|------------------------|----------|
| 3a       | A       | 25/72, DMF                  | 47        | orange oil\(^b\)       | 253 (M\(^+\), C\(_6\)H\(_5\)F\(_6\)NOS\(^+\)) |

\(^a\)Method A: no catalyst; method B: HFP, S\(_x\), DMF, one-pot reaction. \(^b\)Purity 98%, GC–MS, NMR. \(^c\)90% by NMR. \(^d\)Three molar excess of vinylamide was used.

Interestingly, the \(^{19}\)F and \(^1\)H NMR spectra of both compounds 3a and 3b show two sets of signals, probably being a result of restricted rotation around the C–N bond in the amide fragment, similar to restricted rotation of –N(CH\(_3\))\(_2\) in dimethylformamide. Cyclic lactames 2c, d bearing a vinyl group at the nitrogen also undergo reaction with 1 producing the corresponding thietanes 3c, d (Scheme 2).

Scheme 1: Reaction of vinylamides 2a, b with 1.

It should be pointed out that in case of compound 2b the reaction can be performed in an excess of vinylamine as the solvent. The reaction is highly selective (NMR), leading to the exclusive formation of thietanes and fluctuations in the isolated yields of compounds 3a and 3b are connected to the isolation protocol (see Experimental). In contrast to the corresponding cycloadducts of vinyl ethers and HFTA (2,2-bis(trifluoromethyl)-4-alkoxythietanes), which are high-boiling liquids [3], thietanes 3a and 3b are solids at room temperature. The structure of purified 3b was established by single crystal X-ray diffraction (Figure 1).

Scheme 2: Reaction of N-vinylactames 2c, d with 1.

Figure 1: Crystal structure of 3b with thermal ellipsoids drawn at the 30% probability level.

N-vinylcarbazole (2e) was found to have the highest reactivity towards 1. Indeed, when the mixture of 2e and 1 in DMF was heated at 70 °C, no starting carbazole was found in the reaction
mixture after 2 hours (NMR). This reaction led to the selective formation of thietane 3e, isolated in 67% yield (Scheme 3). The structure of 3e was established by single crystal X-ray diffraction (Figure 2).

Interestingly, the $^{19}$F and $^1$H NMR spectra of 3e showed only one set of signals, despite the fact that in the corresponding cyclopropane (prepared by the reaction of compound 3e with PBu$_3$), restricted rotation around the C–N bond was observed [11].

$N$-vinylimidazole (4) was found to have a different reactivity profile. The reaction of 4 with 1 (25 °C, 48 h) unexpectedly led to the formation of thione 5 (rather than the corresponding thietane) as a sole product (NMR, Scheme 4). Thione 5 was isolated in 48–50% yield and its structure was established by single crystal X-ray diffraction (Figure 3).

At elevated temperature, the reaction of 4 with 1 was significantly faster and it was completed after 2 h at 70 °C in DMF. On the other hand, $N$-vinyl-1,3,4-triazole was found to be inert towards dimer 1 and even after prolonged heating (70 °C, 48 h, DMF) only starting materials were observed in the reaction mixture (NMR).

The mechanistic aspect of thione 5 formation is not clear at this point. The formation of the corresponding thiones in the reaction of 1 with $N$-alkylimidazoles was found to be common in nature.

**Experimental**

$^1$H NMR and $^{19}$F NMR spectra were recorded on a Bruker DRX-500 (499.87 MHz) instrument by using CFCl$_3$ or TMS as an internal standard. CDCl$_3$ was used as a lock solvent. GC and GC–MS analyses were carried out on a HP-6890 instrument by using an HP FFAP capillary column and either TCD (GC) or mass-selective (GC–MS) detectors, respectively. Dry DMF (water <100 ppm), vinylamines 2a–e and 4 (Aldrich), sulfur (Alfa Aesar, sublimed, 99.5%, 100 mesh) and hexafluoropropene (DuPont) were purchased and used without further purification. CsF (Aldrich, 99%) was dried at 100–120 °C under dynamic vacuum and stored and handled inside of glove box.

Compound 1 (liquid, purity 93–98%) was prepared by using modified literature procedure reported in [12] and was used without further purification.

Due to the high ratio of sulfur to fluorine, the elemental analysis of new materials was not attempted. The purity of all new compounds established by GC and NMR spectroscopy was at least 98%.
Crystallography
X-ray data for 3b, 3c and 5a were collected at −100 °C by using a Bruker 1K CCD system equipped with a sealed tube molybdenum source and a graphite monochromator. The structures were solved and refined with the Shelxtl [13] software package, refinement by full-matrix least squares on F², scattering factors from Int. Tab. Vol. C Tables 4.2.6.8 and 6.1.1.4. Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC #956557-956559. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, (fax: +44 1223 336033 or e-mail: deposit@ccdc.cam.ac.uk).

Reaction of 1 with 2a–e and 4 (typical procedure)
Method A: To a solution of the corresponding vinyl compound (0.01–0.02 mol) in 15 mL of solvent was added 0.005–0.01 mol of dimer 1. The reaction mixture was agitated for 2–72 h at either ambient or elevated temperature. The reaction mixture was diluted with water (300 mL), extracted with hexane (3 × 50 mL). Combined organic layers were washed by water (3 × 200 mL) and dried over MgSO₄. The solvent was removed under reduced pressure and the residue was purified either by crystallization from hexane or distillation (compound 5).

Method B: Inside a glove box a dry three-necked round-bottomed flask was charged with 0.5–1.0 g of dry CsF. The flask was taken out and equipped with dry-ice condenser, thermocouple, gas inlet tube and 100 mL of dry DMF was added by using a syringe, followed by the addition of 6.4 g (0.2 mol) of sublimed sulfur. The reaction mixture was agitated for 15–20 min, while the temperature was raised up to 35–40 °C. This process was accompanied by the development of a dark blue–brown color of the reaction mixture. Hexafluoropropene 32 g (0.21 mol) was added as a gas to the reaction mixture, and the temperature usually rose to 65–70 °C during the addition and at the end all sulfur went into solution. The reaction mixture was cooled to an ambient temperature followed by the addition of the corresponding N-vinyl compound, and the reaction mixture was agitated for 12–16 h. Afterwards the mixture was diluted with water (500 mL) and extracted with hexane (3 × 100 mL). The combined organic layers were washed with water (3 × 200 mL) and dried over MgSO₄. The solvent was removed under reduced pressure, and the residue was purified either by crystallization from hexane or distillation (see Table 1 for conditions and yields and Table 2 for NMR data).
